Vehicles, on favorable roads, should be required to maintain the maximum catalogued speed. All vehicles should be fitted with lamps, horns and such tools and spare parts as catalogue calls for, but none other. Each vehicle should be in charge of a driver and if desirable a helper who must do all the work of adjusting and repairing, and, in addition, an experienced unbiased observer to note the performance of all work done upon his truck and to keep a thorough record of same.

At the various stops, which will amount to a "control," the machines may be exhibited to interested people, but no work or adjustment of any kind allowed, all of such must be done upon the road. The running schedule of each car should be rigidly insisted upon and no credit given for reaching "control" ahead of its particular schedule.

All gas and oil tanks as well as radiators should be carefully measured previous to the start of the run, in order that each official observer may be able to keep careful record of all gasoline, oil and water used during the test. The circumference of each tire should be ascertained by means of a steel tape previous to the start of the test, in order that the wear may be determined at the completion of the run.

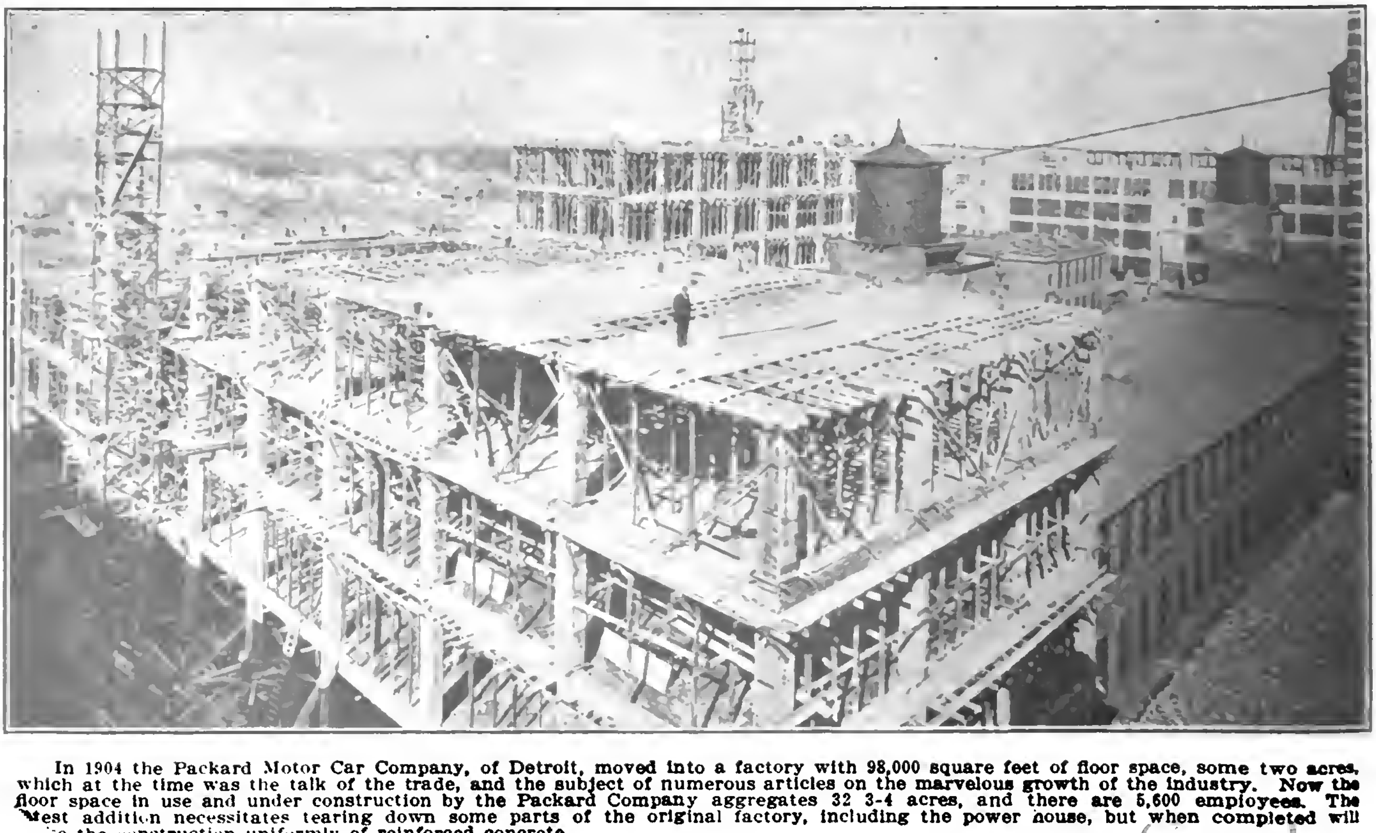
At the completion of the test, the official observers will turn over to those in charge all of their data and awards for reliability and efficiency should be based upon the weight of load carried plus weight of body; gasoline, oil, grease and water used, nature and number of adjustments and replacements made as well as any other trouble together with the mileage and running time. Other regulations may be devised if the situation so indicates.

PLOW FACTORY MAKES ROOM FOR CARS

In order to provide more room for a motor car factory, the Hartford Plow Company, a concern which contributed to the foundation of the Kissel Motor Car Company, of Hartford, Wis., has been sold to the David Bradley Manufacturing Company, of Bradley, Ill. All of the employes of the Hartford Plow works will remain as employes of the Kissel Company.

PLANS FASTER STANLEY STEAMER

Worcester, Apr. 7—The Worcester Automobile Club to-day sent out notices to automobile manufacturers and dealers calling attention to the annual hill climb on Dead Horse Hill, Saturday, June 4. Freeland O. Stanley, of Stanley Brothers, builders of steam automobiles, was in Worcester this week relative to plans for a new racing car.



In 1904 the Packard Motor Car Company, of Detroit, moved into a factory with 98,000 square feet of floor space, some two acres, which at the time was the talk of the trade, and the subject of numerous articles on the marvelous growth of the industry. Now the floor space in use and under construction by the Packard Company aggregates 32 3-4 acres, and there are 5,600 employees. The latest addition necessitates tearing down some parts of the original factory, including the power house, but when completed will make the construction uniformly of reinforced concrete.

Jersey Club Lays Out Interesting Route

PARTICULARLY interesting is the 150-mile course laid out for the road contest of the New Jersey Auto and Motor Club of Newark, which will take place in the early part of June. The pathfinding party went over the route last Sunday and their report on their experiences shows that, in any weather, the course selected will test the stamina of any car. While the weather in June is generally fine, the hills found along the way were steep enough to give the cars an adequate try-out, even in the best of weather.

As it was, the pathfinders had a rather exciting time of it on the slippery dirt roads. One-third of the route is over such going, but the remainder of the trip is over good macadam pavement. The run will start from the clubhouse at 6 o'clock and will extend over 15 hours of running time. While this makes a long day's work for the contestants, it is expected to turn out all right. The route selected is as follows:

The course starts at the clubhouse at Newark, goes out Central avenue to Grove street, over to Plainfield avenue, then through Plainfield, Montclair; at the top of the Montclair hill turns to the right and goes through Pompton, and turns to the left at Newfoundland; then over past Green Pond to Rockaway, Dover; through Dover to Budge Lake, and then to Hackettstown, which will be one of the controls; from Hackettstown the course is laid through Washington, New Hampton, Clinton, Glen Gardner, Flemington, White House, Somerville, Dunellen, Plainfield, Scotch Plains, Springfield and back to the clubhouse in Newark.

MANY ENTRIES IN PRINCE HENRY TOUR

BERLIN, Apr. 1—Entries for the Prince Henry Tour number 50 so far and a large additional list of cars will undoubtedly enter before the books close. William Opel, winner last year, has sent in an entry, making nine Opel cars to participate. A like number of Austrian Daimler cars have been entered. Eight Benz machines and eight Mercedes will take part.

The Berlin Motor and Aero Club's show is attracting an immense amount of attention. The Emperor and royal house are exhibitors, as the auxiliary boats, attached to the royal yachts, are being shown. Two airships and a number of fast motor boats are being exhibited.

NEW REPAIR SHOP FOR WINTON PLANT

Work is being pushed on the new building of the Winton plant at Cleveland, which will be occupied exclusively as a repair shop and parts departments when it is finished. It will be 308 by 70 feet, and of steel and brick construction. Several of the present buildings will be relieved by the new structure, and the facilities of the plant will be materially increased.

REPRISALS ON NEW JERSEY TOURISTS

BOSTON, Apr. 9—If a measure now under consideration by the committee on roads and bridges of the Legislature goes through, Massachusetts will be the first State to retaliate upon New Jersey and other States which do not grant the same privileges to Massachusetts motorists as Massachusetts grants to motorists from those States. It is proposed to limit the time a non-resident can drive in Massachusetts to ten days in any one year and to extend this courtesy only to such States and countries as extend similar privileges to residents of Massachusetts.

SENTINEL TOUR ARRANGED FOR JULY

George A. West, chairman of the contest committee of the Wisconsin State Automobile Association, has sent out a circular to owners and dealers in Wisconsin in regard to the first annual tour for the Milwaukee *Sentinel* $1,000 trophy. The contest will be held during July, and will be under A. A. A. sanction.

"The principal objects of the tour," says Mr. West, "will be to stimulate motoring interest and establish a closer affiliation among dealers and owners throughout the State.

Additional floor space in their factory, to the amount of 70,000 square feet, will be gained by the erection of another big building by Wheeler & Schebler, makers of the Schebler carbureter, at Indianapolis. The building is now in course of construction. It will be three stories, of reinforced concrete and will give facilities for 200 more employees, raising the total product of the company to 1,000 carbureters a day. The company has now installed gas engines developing 350 horsepower.

Elgin Has a Natural Race Course to Consider

CHICAGO, Apr. 18—A stock chassis road race run by the Chicago Motor Club is one of the possibilities of the present season, the first step in that direction being taken last Friday night when a committee from the club attended a meeting called by the citizens of Elgin, Illinois, for the purpose of considering the proposition. Elgin has a natural course which was discovered by Frank Wood, manager of the Chicago Knox branch and a recent inspection of it by the motor club brought about a desire on the part of its officers to use it for racing purposes. Elgin citizens spoken to in regard to the matter were favorably impressed and the meeting was the result.

Big enterprises like this are not put through in a day or even a week, and therefore the meeting did not make any decision in the matter. The Elgin citizens listened to the talk of the motorists as to the advantages the town would derive through having such a big event run at its very doors, seemed impressed with the idea and wound up by appointing a committee consisting of M. M. Cloudman a leading coal dealer of the town; W. W. Willson, publisher of an Elgin paper; and Fred W. Jenks, manager of the opera house. This committee has undertaken to canvass the situation thoroughly and secure from the business men of Elgin a guarantee fund of $15,000 with which to promote the race. This committee has promised to report by May 1 and from the talk of the evening it was believed that the report will be a favorable one.

According to the plans outlined at the meeting, the Chicago Motor Club favors holding the race the latter part of August or the first part of September, possibly asking the contest board of the American Automobile Association to make it a national stock chassis event now that Lowell, Mass., has decided it will not promote that classic this year. It is figured that the expense of putting on such a race would not be great because of the natural advantages offered by Elgin, which is only 38 miles from Chicago and with excellent transportation both by electric trolley and by railroad. The course itself is at the end of Highland avenue and exactly one mile from the business center of the town. A trolley runs to within 100 feet of the course, while at the northwest corner of it is the McQueen railroad station. The course itself is gravel the entire distance, and the exact distance around is 8.4 miles. At the present time the road is in need of scraping, which would not involve a very great expenditure of money. Scraped and oiled, it would be as fast a circuit as Riverhead, Long Island, it is believed, and it ought not to cost much more than $8,500 to put it into racing condition.

It is almost certain that the Chicago Automobile Club will not promote a road race this year, which would leave an excellent opening for the Chicago Motor Club which already has planned a strenuous campaign for 1910, including an economy run on April 28; a demountable rim test, in May; the annual hill-climb at Algonquin in August; and the 1,000-mile reliability in October.

TESTING TAXIMETERS FOR ACCURACY

WASHINGTON, D. C., Apr. 18.—Col. W. C. Haskell, Sealer of Weights and Measures, is the greatest friend the taxicab rider ever had. The picture portrays the Colonel in his original act entitled "Testing a Taximeter." The device by which the Colonel makes the test is an invention of his own, and is probably the only machine of the kind. By attaching the flexible wire of the taximeter to the large wheel the Colonel can find out in one hundred turns of the big wheel whether or not the taximeter is cheating the rider or the chauffeur. One hundred turns of the wheel represent a quarter mile riding by taxicab. Every taxicab in the District has to carry a tested taximeter, and every one of them is tested on Col. Haskell's home-made taximeter tester

Col. Haskell and His Taximeter Testing Device at Work

DEATH CLAIMS AUTOMOBILE MAKER

Thomas M. McLean, president of the Embree-McLean Carriage Company, of St. Louis, died at his home April 9 after an illness extending over several months. He was born at Hollidaysburg, Pa., in 1846 and removed to St. Louis after the great fire in Chicago in 1871 which destroyed the plant of the concern for which he was working. He engaged in the hardware business until about twenty years ago when with James G. Embree he founded the present company. Recently an automobile department was added to the concern and Mr. McLean devoted his most enthusiastic efforts to it.

ELECTRICS ON SHOW AT NASHVILLE

NASHVILLE, Apr. 17—An event of interest to the Nashville public and autoists in particular is the exhibition of the Rauch & Lang Electric Automobile Company of many kinds of handsome cars manufactured by that company. The show was held Thursday, Friday and Saturday of last week. The local agent of the company is A. R. Whiteman. Runabouts, stanhopes, victorias and coupes were on exhibition and demonstrations were given of the "Exide" battery and the mercury arc rectifier, upon the charging of cars.

FIVE ENTRIES FOR GLIDDEN TOUR

Entries for the Glidden Tour have been made by the Premier Motor Manufacturing Company for two cars, which will be numbered 1 and 2. The Moline Automobile Company have entered three cars for the Chicago trophy and they have been given numbers 101, 102 and 103. At least fifty cars are expected to enter.

A. C. A. FINANCES GARAGE PROJECT

Justice Blanchard of the New York Supreme Court granted permission to the Automobile Club of America to mortgage its Fifty-fifth street property for $400,000. Quarter of this will be used to retire a previous mortgage and the rest will be utilized in the building of a luxurious clubhouse and garage.

Endurance Tour To Scranton Will Be Arduous

NORRISTOWN, PA., Apr. 11—A score of local clubmen and Philadelphia newspaper men spent three days last week in spying out the land for the coming third annual endurance run of the Norristown Automobile Club, May 18-19. The six carfuls of pioneers successfully "pathfound" the 327-mile route to Scranton and return, and reported the trip one of the finest in point of scenic attractions and one of the most strenuous as regards physical difficulties ever planned for the club's annual fixture.

The cars which carried the exploring party were an American, an E-M-F, an Otto, a Selden, a Knox and a Premier.

All the preliminaries in the way of securing garage accommodations at the overnight stop and the establishment of intermediate checking stations were attended to, and the running schedule adopted will be close to the 24-mile-an hour maximum allowed by the State law. The itinerary for the two days is as follows:

First Day

	Miles
Norristown (Hotel Montgomery) to Reading (Mansion House)	37.4
To Pottsville (Allen House)	35.6
To Hazleton (Central Hotel)	33.2
To Wilkesbarre (Hotel Sterling)	26.6
To Scranton (Hotel Jermyn)	18.6
	151.4

Second Day

	Miles
To Stroudsburg (Hotel Fulmer)	46.2
To Easton (Hotel Karldon)	27.2
To Allentown (Allen House)	27.3
To Philadelphia (Auto Trade Assn.)	52.4
To Norristown (Hotel Montgomery)	22.5
	175.6

There will be a large proportion of low-gear mountain work from Pottsville to Wilkesbarre on the first day, and from Scranton to Stroudsburg on the second, but the magnificent Pocono scenery and the beautiful Delaware Water Gap section will doubtless be much enjoyed by the travelers.

TIMERS AND SCORERS FORM CLUB

Expert timers and scores of Philadelphia, to the number of twenty-two met last week at the rooms of the Quaker City Motor Club and formed an organization known as the Timers and Scorers Club of Philadelphia. Much difficulty has been experienced in the past in Philadelphia and in fact nearly everywhere on account of amateur work in timing and scoring road and track events, and it is the avowed purpose of the newly formed club to obviate difficulties of that kind.

Prior to the running of such an event as the Fairmount Park Road Race, the club will meet and go over the situation with care, arranging the details so that all contingencies may be met.

They will install automatic electric timing devices and in the Fairmount race they are preparing a score board of an improved type. For the club's roadability tour April 30 to Atlantic City synchronized clocks at Philadelphia and Atlantic City will settle any possible disputes as to running time. E. S. Nyce has been named chairman of the timing committee.

The officers of the club are as follows: Paul B. Huyette, president; George E. Potts, vice-president; A. Paul Oliver, treasurer; I. C. Minford, secretary; Thomas F. Meehan, assistant timer; W. C. Jackson, chief scorer; S. W. Waddington and L. W. Williams, assistant scorers.

ALL-CONNECTICUT RELIABILITY CONTEST

Definite announcement of the details of the All-Connecticut Reliability Contest has been made. The run will start May 19 and will extend over three days, covering about 600 miles. The affair will be conducted by the Contest Committee of the Automobile Club of Hartford, assisted by the automobile clubs of Bridgeport, New Haven, Litchfield County, Willimantic and New Britain.

PREPARE FOR ORPHAN'S DAY

Thursday, June 2, will be Orphans' Automobile Day in New York City. The place as usual, for the day's outing, will be Coney Island, although the exact amusement resort has not as yet been selected. This was decided upon at a well-attended meeting of the Orphans' automobile day committee of N. Y. Col. K. C. Pardee presided, with Alex. Schwalbach as secretary.

MAC MANUS-KELLEY MOVES TO DETROIT

In order to be close to the seat of greatest activity, the MacManus-Kelley Company has removed to Detroit. This big concern, which has a large and important clientele, is now located in the Ford Building, in the Michigan metropolis.

OWEN ON BOARD OF REO COMPANY

Raymond M. Owen, head of R. M. Owen & Company, general sales agents of the Reo Motor Car Company, has been elected vice-president and director of the latter company, having purchased the interest of R. Shettler, retiring vice-president.

In 1901, Mr. Owen was instrumental in placing the largest order on record up to that time for automobiles when he and his partner ordered 1,000 Reo cars for their New York territory. Three years later he arranged to market the entire product of the Reo company and since that time, largely as a result of his business foresight, over 30,000 Reo cars have been sold.

WINNERS IN SAVANNAH ROAD RACE

SAVANNAH, GA., Apr. 18—Winning cars in the three classes that competed in the recent Savannah-Jacksonville road tour were as follows:

Class A—Stevens-Duryea, 24-horsepower, driven by A. Solomon; perfect score. Class B—Cole, 30-horsepower, driven by R. S. Brown; perfect score. Class C—Maxwell, 12-horsepower, driven by Mrs. L. W. Hazard, and Hupmobile, driven by Chris Jacobs. They were tied with a perfect score.

BUICK WINS MATCH HILL CLIMB

W. J. Stoddard, of Atlanta, was obliged to act as host at a dinner party held at the Hotel Piedmont of that city as the result of a hill-climbing contest in which his car, a National 40, met defeat in the match event on Stewart avenue. A Buick 16 proved the winner. William Oldknow was the driver of the victor, as well as guest of honor at the dinner.

William Oldknow in Buick, Winner of Match Hill Climb at Atlanta

County Bridge Between Middletown and Shelbyville, Ky., Where Louisville Enthusiasts Met the Glidden Pathfinder

Glidden Pathfinder Has Varied Experiences

EVERY variety of automobile experience was enjoyed during the first week of the 1910 Glidden Tour, pathfinding expedition. All kinds of weather conditions have prevailed, except sandstorms and blizzards, but aside from delays, caused by washouts and swollen streams, satisfactory progress has been made.

Scout Lewis and his party have had a rather strenuous time in spots, but, as a whole, the trip has been enjoyable so far.

From Cincinnati to Lexington the roads are fine, having a limestone foundation and kept in excellent repair. From Lexington to Louisville the same delightful road conditions prevail, or at least they will prevail when the tour proper commences. A series of terrific rainstorms has swept the valley recently and, as a result, little streams boom along with a picturesque savagery that will undoubtedly be tamed by the middle of June.

The run to Nashville was generally pleasant, but in spots the pathfinders had to lend a shoulder or do some wading. A big welcome was given the car at Nashville. This city prides itself upon its progressive spirit, prosperous commerce and pretty girls, and the reception was particularly warm and hospitable. Nashville will be a night control of the tour and the advent of the pathfinders had the effect of arousing such a furor of automobile enthusiasm, that it is quite likely that before the tourists arrive there will be a full-fledged automobile club to act as hosts.

E. L. Ferguson, tour manager, and Mr. Lewis, scout, were called upon for advice as to the formation of the club. They recommend a democratic body with a low entrance fee and a wide scope of activity. The city has over 800 automobiles in use.

From Nashville the car crossed into Alabama where swollen streams and deep roads resulted in considerable hard work and more delay.

The weather began to clear and the going proved easier just before the close of the first week, but the Alabama rivulets effectually prevented anything like good time. Across the Mississippi River, the Arkansas roads are reported swampy and the trip across that State and on to Dallas will doubtless consume more time than was anticipated in making the preliminary schedule.

WILDWOOD CLUB LAYS PLANS FOR RUNS

PHILADELPHIA, Apr. 11—At a meeting last Wednesday night, the plans of the North Wildwood Automobile Club for the coming season were officially decided upon. They include the usual July 4 meet on the Wildwood Speedway, preceded by a club run from this city; a similar meet on July 30; a motorcycle meet on August 6, and the Labor Day wind-up on September 5, when an effort will be made to have all the national cracks on hand for a series of short-distance events on the Speedway.

The club's $12,000 club house, located on the Speedway, has been refitted, and the membership, now numbering 104, will, it is believed, be increased to upwards of 200, before Independence Day.

Arrangements were made for the entertainment of the contestants in the endurance run of the Motor Club of Harrisburg, who are scheduled to spend the night of May 10 at Wildwood.

A score of ladies, who compose the Ladies' Auxiliary were present at the meeting and the supper which followed.

ELKHART'S PLEA FOR GOOD ROADS

ELKHART, IND., Apr. 18—Co-operation of farmers and residents in the bettering of conditions of country roads is asked by the Industrial Association of this city. In an endeavor to prove to every resident of the northern part of the county the benefit to be derived from good roads, the association will shortly send out pamphlets to 10,000 persons giving statistics and facts to prove the need of such improvements. The book is entitled "Elkhart's Plea for Good Roads."

GARAGE OWNERS FORM ORGANIZATION

Garage owners of New York formed a preliminary organization Tuesday for the purpose of effecting a number of general reforms in that line of industry. The meeting was held at Reisenweber's and was attended by over a score of leading members of the business. The objects, as stated at the meeting, are to eliminate the criminal element among chauffeurs; to provide for concerted action and to foster the best automobile interests.

Durant and Morgan Deny Merger Reports

REPORTS circulated rather vigorously during the past week to the effect that J. P. Morgan & Company were preparing to merge several large automobile interests, have been met with sharp denials. The chief of these rumors was that the United States Motor Company and the General Motors Company, with all their ramifications, were to be amalgamated. J. P. Morgan, Jr., entered a positive denial of the alleged merger as far as the great banking house is concerned, and W. C. Durant of the General Motors Company was equally forceful in stating the position of his company.

"So far as they refer to General Motors," said Mr. Durant in speaking of the reports, "there is not a word of truth in them."

"The General Motors Company is not interested in any merger, pending or prospective, and I wish to state that the published and reiterated reports that J. P. Morgan & Company had any part in the formation of the General Motors Company is without semblance of truth. I might add that J. P. Morgan & Company have no interest in General Motors at present as far as I know.

"For over a year," continued Mr. Durant, "this company has carefully refrained from denying fanciful and baseless stories published about its antecedents and activities. Such denials would congest news space in many publications and if we had attempted to make them, the work involved would have proved burdensome. Another viewpoint from which this situation might be examined is that the public is likely to look upon denials of news and alleged news as a variety of undignified publicity.

"The company wishes to avoid giving ground for such an impression, which ought to be sufficient reason for our silence during a long period of misrepresentation. The company is not for sale."

A. L. A. M. SUING AND ALSO SUED

Litigation of the cross-fire order, based upon the Selden patents has been started for and against the Association of Licensed Automobile Manufacturers. The association recently filed seven suits at Detroit, naming as many unlicensed makers as defendants. These companies are: Owen, Abbott, Demot, Warren-Detroit, Paige-Detroit, Velie and Parry motor car companies.

Wednesday advices from Milwaukee tell of the filing of a suit for $500,000 damages by the Velie Motor Company of Moline, Ill., against the A. L. A. M. In the complaint it is alleged that the efforts to enforce the Selden patents works as a restraint of trade, within the purview of the anti-trust act.

MAKING PROGRESS IN SELDEN CASE

Judge Hough of the United States Circuit Court on Monday heard arguments with regard to a supplementary bill filed by the complainants in the suit of The Electric Vehicle Company and Selden against the Ford Motor Company, Panhard et al., to substitute the Columbia Motor Car Company for the Electric Vehicle Company, as party complainants. This action would have been unnecessary if the proceedings under the original suit had been followed out, but at the last moment the Ford company declined to accede to the substitution and the supplemental bill was resorted to.

The court allowed the attorneys until Wednesday to submit briefs covering the law points involved.

Los Angeles Meet Proves Success

ONE of the most spectacular race meetings ever given in this country was concluded when the motordrome meet at Los Angeles was finished last Sunday. The races demonstrated that the track is fast and comparatively safe and records fell like tenpins before the rush of the flying motors. Many of the contests were won by narrow margins and accidents were remarkably few.

The summaries:

April 13—First heat, ten-mile, free-for-all, Darracq (Kerscher) first, Fiat (De Palma) second. Time, 7:01.

Five-mile, free-for-all handicap, Stoddard-Dayton (Livingstone), 12 seconds, first; Marmon (Harroun), 10 seconds, second; Isotta (Marquis), 11 seconds, third. Time, 3:50.55.

Fifty-mile free-for-all, Fiat (De Palma) first, Stoddard-Dayton (Livingstone) second, Marmon (Harroun) third. Time, 37:55.53.

April 15—Ten-mile, stock chassis, 161-230 cubic inches, Buick (Nikrent) first, Cole (Endicott) second, Firestone (Miller) third. Time, 8:40.17.

Ten-mile, free-for-all, Fiat (De Palma) first, Fiat 90 (Bragg) second. Time, 7:11.62.

Ten-mile, free-for-all, stock chassis, 600 cubic inches, Fiat, (De Palma) first, Knox (Oldfield) second, Marmon (Harroun) third. Time, 7:38.23.

Ten-mile stock chassis, 451-600 cubic inches, Knox (Oldfield) first, Fiat (De Palma) second. Time, 7:22.92.

Fifty-mile, stock chassis, 390-450 cubic inches, Marmon (Harroun) first, Marmon (Wade) second. Time, 39:53.55.

April 16—Five-mile, stock chassis, 301-450 cubic inches, Buick (Nikrent) first, Marmon (Harroun) second, Marmon (Wade) third. Time, 3:56.68.

Ten-mile, stock chassis, 451-600 cubic inches, Knox (Oldfield) first, Stoddard-Dayton (Livingstone) second. Time, 7:20.66.

Two-mile match race between Fiat (Bragg) and Benz (Oldfield), won by Fiat. Time, 1:28.73.

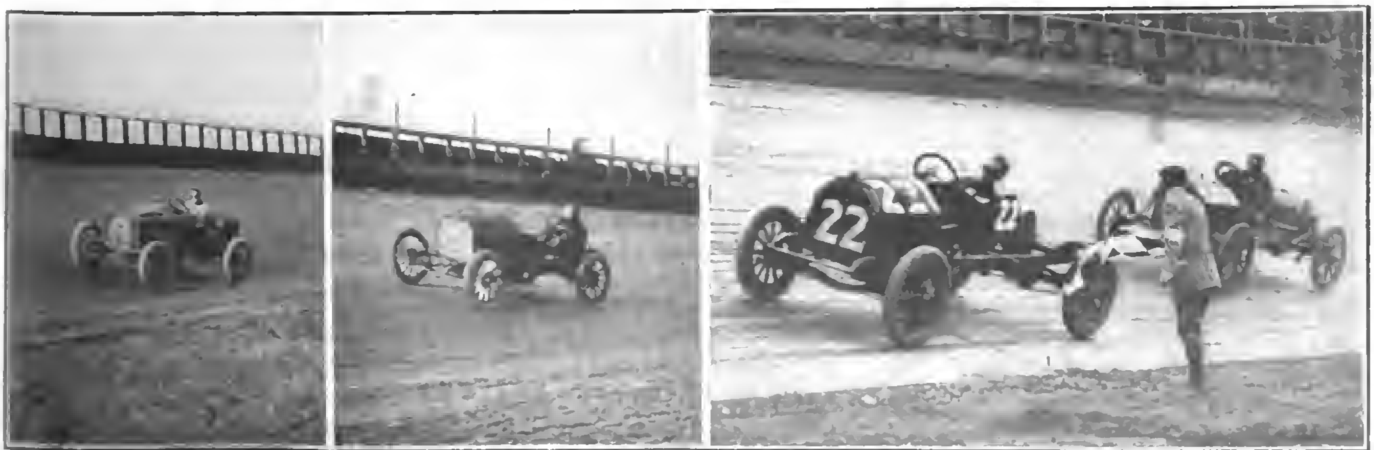
April 17—Ten-mile, 161-230, Cole (Endicott) first, Warren-Detroit (Miller) second, Buick (Nikrent) third. Time, 8:46.74.

Three-mile, stock chassis, Three Fords, driven by Pratt, Stearns and Olsen, finished in order. Time, 4:62.

Ten-mile, 301-450, Buick (Nikrent) first, Marmon (Harroun) second, Marmon (Wade) third. Time, 7:36.61.

Two-mile, second heat of match race, Fiat (Bragg) first, Benz (Oldfield) second. Time, 1:19.48.

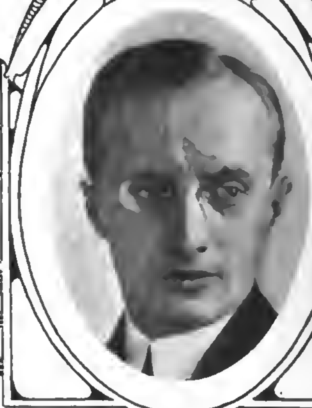
One-hundred mile, stock chassis, under 600, Marmon (Harroun) first, Buick (Nikrent) second, Knox (Oldfield) third. Time, 1:16:21.80.



Kerscher in Darracq, Robertson in Simplex, and Endicott in Cole Winning Ten Mile Stock Chassis Race at Los Angeles

Among the Garages

Fleet of White Taxicabs owned and operated in Boston by Saunders & Butler. This form of conveyance has become deservedly popular in the Hub



Frank G. Van Dyke, president of the Van Dyke Motor Car Company

Ground has been broken at Newport, R. I., for the most elaborate private garage in America for Mr. and Mrs. Edward J. Berwind, close to their estate on Bellevue avenue, and it will cost about $150,000. Of limestone and fireproof material, the building will measure 125 by 70 feet. It will be two stories high and will have sunken wells for gasoline. The main part of the building, with its wings, will have in the center an immense ring, where Mr. and Mrs. Berwind or their guests can try out new machines. The garage will be roomy enough for storing eight machines.

John Conway, T. W. Orbison and others on Washington street, Appleton, Wis., have become associated for the purpose of building a large fireproof garage at a cost of $25,000. The garage will be leased by Harry Griffin and Chester Scott, who have been operating a garage in connection with the agency for the Kissel, Buick and Cameron, in the former Ullman livery stable. The garage will be 50 by 125 feet, one story high, of solid brick and concrete. Fire walls will separate the garage from the repair shop at the rear, making it possible to do repair work at night by artificial light, without danger.

The Penn Auto Supply Company which recently opened a branch at 1407 Filbert street, Philadelphia, opposite the City Hall and Broad Street Station, has inaugurated an innovation by making the branch an "open-at-night" establishment, and the first week of the experiment has proved so successful that President John W. Lee contemplates making it a permanent feature. The same idea will be followed out at the company's Atlantic City branch during the Summer season.

The Van Da Grift Auto Car Company will open its new garage in Louisville about May 15. The plant will be fireproof, steam heated and modern in every respect. Both gasoline and electric cars will be handled and a complete machine shop in connection will furnish the means of reconstructing cars from wheelbase to canopy.

Howard G. Robinson, for several years garage manager for the Rauch & Lang Company, and A. J. Mills, who has had ten years' experience with gasoline cars, have opened a garage on Emily street, Cleveland. Before formally opening the new garage the two men had practically contracted for enough cars to fill it.

G. H. Luck & Company, Keene Valley, N. Y., have just completed their new fireproof garage on Market street. It is up to date in every respect. A first-class repair man will be kept, and any job outside a factory can be done. A full line of automobile supplies will be kept.

The Bound Brook Garage, Bates-Wilder Company, at North Scituate, Mass., is making an addition of about 1,500 square feet to the fireproof garage and is building a new office. The company is local agent for the Maxwell line.

Gadsden, Ala., is rejoicing over the starting of work on the garage of the K.-E. Auto & Electric Company on Broad street, between Fifth and Sixth. The building will be 50 by 100 feet, one story in height and fireproof, designed especially with view to occupancy as a garage.

The Toledo Garage & Supply Company, of Toledo, Ohio, was incorporated with a capital of $5,000 by George T. Browning, F. M. Bushong, E. E. Sheppard, Charles A. Langdon and Alvin C. Jones.

The Portage Motor Car Company, of Akron, Ohio, was incorporated with a capital stock of $5,000 by Louis P. Dettling, Emma C. Dettling, Albert Buehrle, B. Buehrle and Albert J. Engle.

The Howard-Cregor Company, of Nashville, will move into its new garage within the next week. The location is ideal, on Broadway, and the building is well adapted for its purpose.

The Rhinelander Iron Company, of Rhinelander, Wis., has started construction work on a new repair shop, 30 by 50 feet. The new building will have ample garage facilities.

Charles D. Fenn, of Antigo, Wis., has started the erection of a garage of solid brick, 26 by 75 feet in dimensions.

Brief Personal Trade Mention

H. A. Brown, Jr., formerly on the staff of the Hyatt Roller Bearing Company, has accepted an offer from the Holcomb Steel Company of Syracuse, N. Y. Mr. Brown's headquarters will be in the New York branch of the concern which makes a full line of automobile steel.

Harvey H. Colbath, manager of the Philadelphia Morgan & Wright branch, was married last Wednesday in the Protestant Episcopal Church of the Annunciation, to Helen V. Cadwalader. They are now enjoying their honeymoon in the South.

Alexander Winton, accompanied by Mrs. Winton, sailed for a trip to Europe on the *Mauretania*, April 13. After a short visit in Scotland, Mr. Winton expects to take delivery of his Antoinette monoplane at Paris.

George A. Horner was promoted to the post of general manager of the Rapid Motor Vehicle Company, of Pontiac, Mich., April 1, vice Harry Hamilton, who died recently.

C. Booth Tomlins, of Chicago, has been appointed manager of the motor car department of the W. H. Hobbs Supply Company, of Eau Claire, Wis.

F. A. Flint, assistant sales manager of the Moon Motor Car Company, was married on April 14 to Miss Nellie Allie Harper, of St. Louis.

H. J. Newman, designer of the Coates-Goshen Automobile Company, of Goshen, N. Y., resigned his position April 1.

With the Agencies

Group of finished Kisselkars, which were formed in line and driven from the factory at Hartford, Wis., to Chicago on account of shortage of freight cars there

S. H. Mora, president and general manager, Mora Motor Car Company

By a decision rendered by Attorney-General Denman of Ohio, it is held that all dealers in motor cars must take out licenses as such. The term agent means one who either handles automobiles for himself or for someone else. The licenses that are to be given agents are the same as those given manufacturers of automobiles.

A branch of the Franklin Automobile Company has been formed at Baltimore with Edward W. Orr as manager. The company has established headquarters at Maryland and Mount Royal avenues. The Franklin car was formerly in the hands of the Mar-Del Company, now exclusive agent for the Packard cars.

J. T. Sweeney, until recently purchasing agent for the Times Square Automobile Company of New York and Philadelphia, has organized the Sweeney Automobile Company and opened salesrooms and offices at 208 North Broad street, where he will deal in high-grade used cars exclusively.

F. C. Reamer, Jr., and Carroll A. Haines, with headquarters at the Park Garage, 2214 Spring Garden street, have been awarded the Philadelphia agency for the Baker electric, which was bandled in the Quaker City some years ago by the Foss-Hughes Motor Car Company.

E. R. Jackson, who formerly managed the White branch in Baltimore, and later connected with the Studebaker branch in Philadelpbia, has transferred his allegiance to the Longstreth Motor Car Company, Philadelphia agents for the Pullman and Alco.

The Hokanson Automobile Company, of Madison, Wis., bas established a branch at Monroe, Wis. Temple Robson, of Benton, Wis., and William G. Breessee, formerly associated with the Holloway Auto Company, of Monroe, are managers.

Frank Lawell, manager of the Franklin Motor Car Company, of Columbus, has taken the Central Ohio agency for the Inter-State. The agency will be handled from the office of the Franklin Motor Car Company, North Fourth street.

A partnership consisting of E. E. Minick, H. S. Pitz and Dr. Sniveley has been formed to take over the Central Ohio agency for the Cole "30," which has been handled by John T. Gill. The agency covers six counties in Central Ohio.

Ralph P. Dowse and L. H. Christian, of Detroit, have taken over the agency of the Car Makers' Selling Company in the Southwest, and will handle the Anhut, De Tamble and Cutting cars from Kansas City headquarters.

August Huerth, of Madison, Wis., and Jobn Knipschield, of Merrimac, Wis., have opened a garage and repair shop in the Gaukel Building at Sauk City, Wis. They will represent the Oldsmobile and Buick.

F. S. Hyatt, purchasing agent of the Columbia Motor Car Company at Hartford, and its predecessor in business, the Electric Vehicle Company, has resigned and has been succeeded by Lyman Smith, of that city.

Fred. E. Devlin, formerly connected with the Pierce-Arrow agencies in Baltimore and Pbiladelphia, has been appointed manager of the Hills Motor Car Company, Philadelphia agents for the Royal Tourist.

Dr. Wadsworth Warren, Detroit pbysician, bas joined the forces of tbe General Motors Company, and will have charge of the racing team which will be put out by the Buick Company this Summer.

Benjamin O. Willebrands, until recently general manager of the Willebrands Machinery Company, is now associated with John P. Schneider, veteran automobile dealer, in Detroit.

The Ford Motor Company has leased a large four-story brick building at 5929-5931 Baum street, East End, for five years and will remodel it for its permanent city headquarters.

On page 533 of The Automobile, published March 17, the picture of a fire department automobile which is credited to Taunton, Mass., should be credited to Tampa, Fla.

The Burton-Littlewood Company, 112-114 East Wilson street, Madison, Wis., has been made sales agent for the Studebaker line in a large territory of Western Wisconsin.

D. Tbomas Kennan has been appointed manager of the branch of the Swinehart Tire and Rubber Company just established in Philadelphia, at 1437 Vine street.

The agency of the Mea Company, high-tension magnetos and the S. R. O. ball-bearings, has removed to larger quarters at 1777 Broadway, New York.

H. L. Hoppe, former agent of the Hupmobile, has taken the Hartford agency for tbe Warren Detroit, another of the Western newcomers in that section.

R. D. Rockstead, 323 East Wilson street, Madison, Wis., has been appointed southern Wisconsin representative of the Warren-Detroit.

The Swinehart Tire & Rubber Company has opened a Boston branch at 727 Boylston street. A. J. Greene is in charge.

The Deere Implement & Vehicle Company, of Montgomery, Ala., will handle the Jackson this year.

Dinsmore & Calkins, of Delavan, Wis., have been appointed agents for the Maxwell and Overland.

W. J. Cochrane & Son, of Fox Lake, Wis., are new agents for the Jackson and Fuller lines.

E. E. Houk, of Nashville, Tenn., will handle the Jackson line of automobiles the coming year.

Making a Demonstration

A

C

D

A—Alco Car in Fire Department Service at Schenectady, N. Y.
B—Palmer-Singer Car in Which Lewis J. Lampke Made Trip to Coast
C—Lozier Lakeland Model Used by Joseph M. Gilbert of Tire Fame
D—Hupmobile Which Will Prove Strenuous Ability in Flag to Flag Race

(A) In view of the well developed inertia of the average municipality, those who have occasion to note the progress which is being made in the adaptation of automobiles for fire department service are much inclined to the opinion that it will be but a matter of a year or so when the chief and the field officers of every department of any moment in the country will respond to alarms with the speed which comes from using automobiles. As an example of this character of activity, this illustration presents a 40 horsepower Alco operated by Chief Engineer Henry R. Yates, of the Schenectady, N. Y., Fire Department.

(B) The time has now arrived when family tours extend across the continent, not infrequently, and it is in these long jaunts that evidences of mechanical refinement of automobiles drop out. Obviously it would be an enormous undertaking, fraught with much hardship, were tours of great length undertaken, unless the automobiles used could be implicitly relied upon. Lewis J. Lampke, wife and family, in a Palmer-Singer 40 combines business with pleasure in a trip which he is making from the Atlantic to the Pacific, in which he has scheduled calls upon his customers.

(C) That the gun-boat type of body offers unusual opportunity for touring under pleasurable conditions seems to be a fairly established fact, and Joseph M. Gilbert, manager of the Continental Caoutchouc Company, after a most pleasant experience in a Lozier Lakewood model, is an enthusiastic advocate, claiming that it lends itself either to rapid work or loafing.

(D) The Flag to Flag Contest offers wide opportunity for the strenuous testing of automobiles, and E. W. Swanbrough, of Denver, has entered a Hupmobile, with a view to showing how well this make of car will travel from Denver to Mexico City. The distance strings out on the tape for long, but this is not the important matter; the car will have to negotiate 1,000 miles of sand-strewn flats, some scores of troublesome rivers, and a desert or two.

MOTOR RACING ASS'N CLUBHOUSE

FORMAL opening of the new city clubhouse of the Motor Racing Association at 304 West Fifty-eighth street took place recently when a reception was held to the newly elected associate members of the association. The commodiousness and attractiveness of the club building was a decided surprise to the several hundred people who were present. These were welcomed by C. F. Wyckoff, president; E. R. Hollender, vice-president; Carl H. Page, treasurer, and W. C. Allen, secretary.

The building, an old brownstone mansion, has been fitted for club purposes and has every equipment and convenience to make a comfortable and attractive town house for those interested in speed competition or in the trade. On the main floor are located the offices of the M. R. A., a reception and a dining room. On the floor above are billiard and pool tables. Card and writing rooms occupy the third floor, while on the fourth floor are located several suites of sleeping apartments.

Office

Card Room

Seventieth Street Front of Winton Combined Office, Sales, and Garage Building, Showing Two Garage Entrances

Prominent New York City Garages—II—Winton

IN a city the size of New York there are many large garages which can do very well taking in but one class of or one make of cars, that is, the product of but one maker. In this class might be described the garage of the Winton Company, located well up in Automobile Row, at the northeast corner of Broadway and West Seventieth street. While other makes of car are not refused, it has just happened that the clientele of this garage numbers so many Winton owners as to take up all of the available space, and thus, the place has received the name of being exclusively a Winton garage, which of course, is not the case.

The garage part of the building—the Broadway front is utilized as a salesroom and offices for the New York Winton branch—is located on the entire second, third, and fourth floors of the building, the entire roof, and the Seventieth street front of the ground floor, there being no basement. The entrance is

View on Second Floor, Devoted to Live Storage. Also Third Floor, for Dead Storage

Fourth Floor Showing Machine Shop, Also Roof with Repair Work in Progress on Two Cars

on the Seventieth street side, through two twelve-foot doors, between which are located the garage offices and checker.

Driving straight in to the center of the building, the elevator is reached, which serves the floors above. The whole available space of the ground floor—necessarily small on account of leaving space from both the doors to the elevator—is used for live storage, as is also the whole second floor. Above that, the third floor is given up wholly to dead storage, while the fourth floor houses the repair shops, some dead storage, and when pressed for room, some cars on live storage also. Above this, the roof shows a unique feature, being finished off just like any of the lower floors, excepting only for the covering, which is but 25 or 30 feet wide around the south and west sides. Under this roofed part, are placed electric lights, while the elevator shaft carries up, that making of the roof an additional floor of full size in fair weather, and about half size during bad, cold, or inclement weather. At the time the pictures shown herewith were taken, this roof was being used for dismantling two cars, preparatory to spring overhauling and repairing.

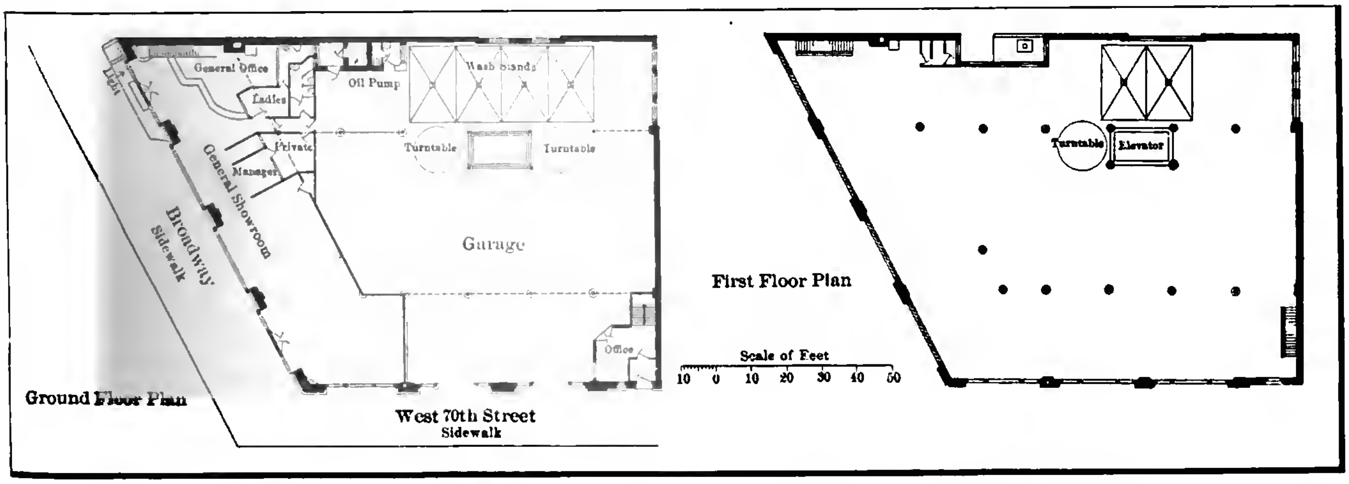
The building is comparatively new, having been built but three years ago, that is, in the fall of 1907, and like all modern buildings, is well equipped. Gasoline and oils are kept on the ground floor, a special room containing the latter, in barrel lots, while the former, is housed in a 400-gallon tank, in a separate room, of brick, and kept locked at all times.

The full capacity is said to be no less than 110 cars on live storage and 75 on dead storage, the whole capacity being slightly less than 200 cars, the present distribution being according to the figures given. To handle this number of cars, and handle them properly, about 50 to 55 men are employed, exclusive of sales and office employees, who are kept separate.

In the arrangement of the distribution of the cars, the vital point in a city garage where space is at a premium, the arrangement is good, consisting of the aforementioned elevator in the center of the building with turntables on each side of it on the ground floor, and on but one side on all other floors, except the roof, where there is no turntable. Not all of the turntables are in constant use, they being of an old pattern, but on the floors where they are in working order, the men find them a very useful adjunct, saving as they do much manual labor in pulling and hauling the cars around, as well as saving the tires.

On the ground floor are also located the lockers for chauffeurs, the rest or play room for the latter, as well as the washstands for the cars. On each of the upper floors, there is placed one or more additional washstands, so that the car may be washed and then taken to its proper floor, or taken up to the floor on which it belongs and washed there, just as circumstances would seem to indicate which course was best.

The machine shop is complete as garage machine shops go, and has in connection with it a very large stock room, containing not only repair parts for all model Winton cars, but also a good supply of standard parts, bolts and nuts, bar stock, and similar material, which would be necessary in the repair of any make of car.



Winton Garage—Ground Floor and Typical Higher Floor Plans, Showing Irregular Shape of Building

THE LAW OF THE ROAD

(*Continued from page 769.*)

RIGHT OF WAY

Police, fire department, fire patrol, traffic emergency repair, U. S. Mail vehicles and ambulances shall have the right of way in any street and through any procession.

Subject to Section I of this article, everything being equal, all vehicles and street cars going in a northerly or southerly direction shall have the right of way over all vehicles and street cars going in an easterly or westerly direction.

Subject to Section I of this article, street cars shall have the right of way between cross streets, over all other vehicles; and the driver of any vehicle, proceeding upon the track in front of a street car, shall immediately turn out upon signal by the motorman, driver or conductor of the car.

No vehicle or street car shall so occupy any street as to interfere with or interrupt the passage of other street cars or vehicles.

A vehicle waiting at the curb shall promptly give place to a vehicle about to take on or let off passengers.

The driver of a vehicle, on the approach of a fire engine or any other fire apparatus, shall immediately draw up said vehicle as near as practicable to the right-hand curb and parallel thereto and bring it to a standstill.

The driver of a street car shall immediately stop said car and keep it stationary upon the approach of a fire engine or other fire apparatus.

MAXIMUM SPEED

No vehicle shall proceed at any time at a greater speed than the law allows and is safe and proper under the conditions then obtaining.

No vehicle shall cross any street or avenue running north and south or make any turn at a speed rate exceeding one-half its legal speed limit.

OVERTAKING STREET CARS

A driver of a vehicle overtaking a street car shall exercise due caution not to interfere with or injure passengers getting on or off said car.

GENERAL PROVISIONS

No one shall drive a vehicle that is so covered in or constructed as to prevent the driver thereof from having a sufficient view of the traffic following and at the sides of such vehicle.

No one shall drive or conduct any vehicle in such condition, so constructed or so loaded as to be likely to cause delay in traffic or accident or injury to man, beast or property.

No one shall so load a vehicle, or drive a vehicle so loaded, with iron or other material that may strike together without its being properly "deafened" so as to cause no unnecessary noise.

No one shall ride upon the rear end of any vehicle without the consent of the driver, and when so riding no part of the person's body shall protrude beyond the limits of the vehicle.

RIGHTS AND DUTIES OF DRIVERS AND PEDESTRIANS

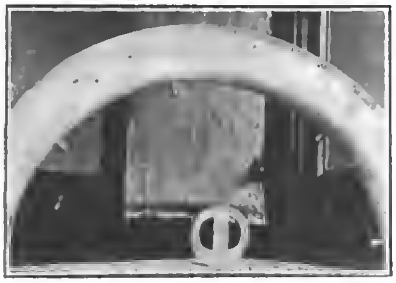
The roadbeds of highways and streets are primarily intended for vehicles, but pedestrians have the right to cross them in safety, and drivers of vehicles and street cars must exercise all possible care not to injure pedestrians. Pedestrians should, on their part, never step from the sidewalk to the roadbed without first looking to see what is approaching, and should not, needlessly, interfere with the passage of vehicles or street cars.

By crossing a street as nearly as possible at right angles, preferably at a regular crossing, and when a traffic policeman is stationed there, by waiting for his signal, pedestrians will greatly add to their own safety, facilitate the movement of traffic, and make it much less difficult for the horses, which often have to be reined in suddenly and painfully to avoid careless and unthinking pedestrians. Nothing in the foregoing should excuse drivers from constant vigilance to avoid injury to pedestrians under all conditions.

The word vehicle includes equestrians, led horses and every-

PROMINENT ACCESSORIES

The old problem of producing a puncture-proof automobile tire without reducing air space and the resiliency (which is the main purpose of a tire) too much, has found a new solution through the efforts of Dr. T. J. Cooper, of Paterson, N. J., who has produced the "Fear-Naught" tire shown in the accompanying illustration. Dr. Cooper is a veterinary surgeon, like Dunlop, the erstwhile inventor of the pneumatic tire, and has spent a good part of the past eight years in bringing his invention into practical shape, the difficulties lying mostly in perfecting manufacturing processes so as to reduce cost and weight to a minimum. It can now be made either as a plain single-tube tire to be fastened to the rim and prevented from creeping by means of metal studs projecting at intervals from the inner periphery, or provided with flanges of rubber and fabric for application to the universal clincher rim. A "Fear-Naught" tire of the latter type of 3⅛-inch diameter and adapted for a 30 by 3-inch rim weighs 22 pounds, while an ordinary clincher tire of 2⅞-inch diameter. adapted for the same rim, weighs 15 pounds. The difference is due mostly to the thick vertical web, made of rubber 50 degrees pure, which separates the air space in Dr. Cooper's tire into two parallel divisions, and to which are due the tire's non-collapsible and almost puncture-proof qualities.



View of Cooper Tire Showing Lugs

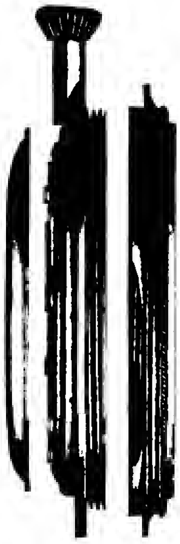
The tire is inflated through a single valve, from which the air duct forks Y-like through the vertical web, and the apertures to each of the air chambers are closed with one-way rubber flap valves admitting air during inflation but preventing one chamber from losing its inflation if the other should happen to become punctured. Even if both chambers are deflated, however, the tire still supports its load and no rim cutting takes place, as has been proved to users by severe and long-continued tests, especially in Paterson, where several automobiles have been fitted with these tires for four years. The inventor himself used one on a rear wheel of an automobile, and wore out three other pneumatic tires on the other rear wheel in competition with it. Dr. Cooper is negotiating with the Board of Trade of his home town with a view to arranging for the establishment of a manufacturing plant.

Section of Cooper Tire with Air Space

Carbon removal is at best a difficult job, and one that is never welcome to the amateur owner, nor to the professional chauffeur. So, it is with great relief that car owners and drivers are now turning to the various preparations on the market for doing this work, but doing it insidiously and quietly, without tearing down the engine. One of these decarbonizers is called by the makers, the Flash Manufacturing Company, Zanesville, Ohio, "Flash," from its very rapid action. This decarbonizer is a compound dissolvent in dry form, that is, a powder, which is placed in the cylinders, is aerated by the combustion, and the mephitic vapors given off check the formation of carbon, or if already there, loosen it from the cylinder or other walls, so that it is blown out through the exhaust pipes.

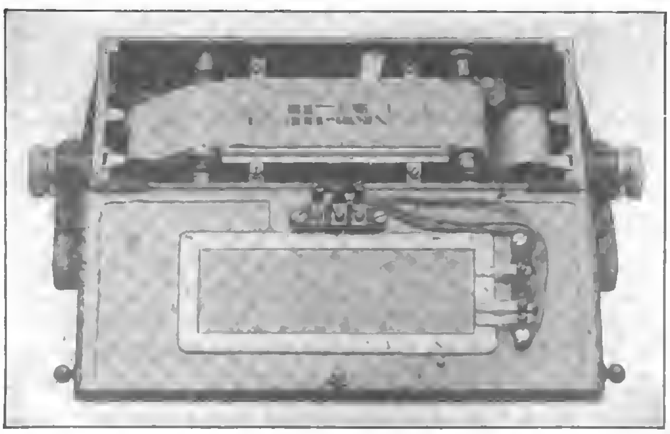
A new spark plug, the Blue Blaze, is that made and sold by the National Steel Products Company, Lorain, Ohio. The greatest features of this plug is that the lower or firing end is closed with the exception of a single very small diameter hole. The spark is thus made inside of the body of the plug, and passes out to the combustion chamber through the small hole. The result is that no soot or carbon can accumulate, the action being that of self-purification. So well has this worked in actual practice that a Blue Blaze plug has been known to run sixteen months without removal from the cylinder, to say nothing of cleaning. The plug is made with both porcelain and mica cores, the buyer being offered his choice.

A new watch for use in broughams, landaulets, and other closed cars is that of the New England Watch Company, Waterbury, Conn. As the illustration shows, the back of the watch snaps on, making the delicate mechanism of the inside dust and damp-proof. The watch is fitted to the toilet case by screwing the front or bevel to the flange, so that the watch and toilet case are the same as if made in one. The dial has heavy black figures and hands, making it an easy matter to read the time by means of it at any time of day or night. The movement is very high class, being fitted with a double-roller lever movement, seven jewels, Breguet hair spring, cut expansion balance, etc.



New England Watch Company's Limousine Watch

Since one's location on the road is fully as important as the speed, the time, or the condition of the road, a new device, herewith illustrated, should find favor with automobilists. This is a position indicator, which shows at all times the exact location of the machine upon the road which is being traveled. In appearance, it is a square wooden box about 6 in. high and wide by 10 in. long, which is fastened to the dashboard. On the upper glass face, a ribbon or map passes under a thread which indicates the automobile position. The map, corresponding to the route traveled, and being geared to the wheels, the correct position is always shown.



Hofmann Location Indicator, a New Device

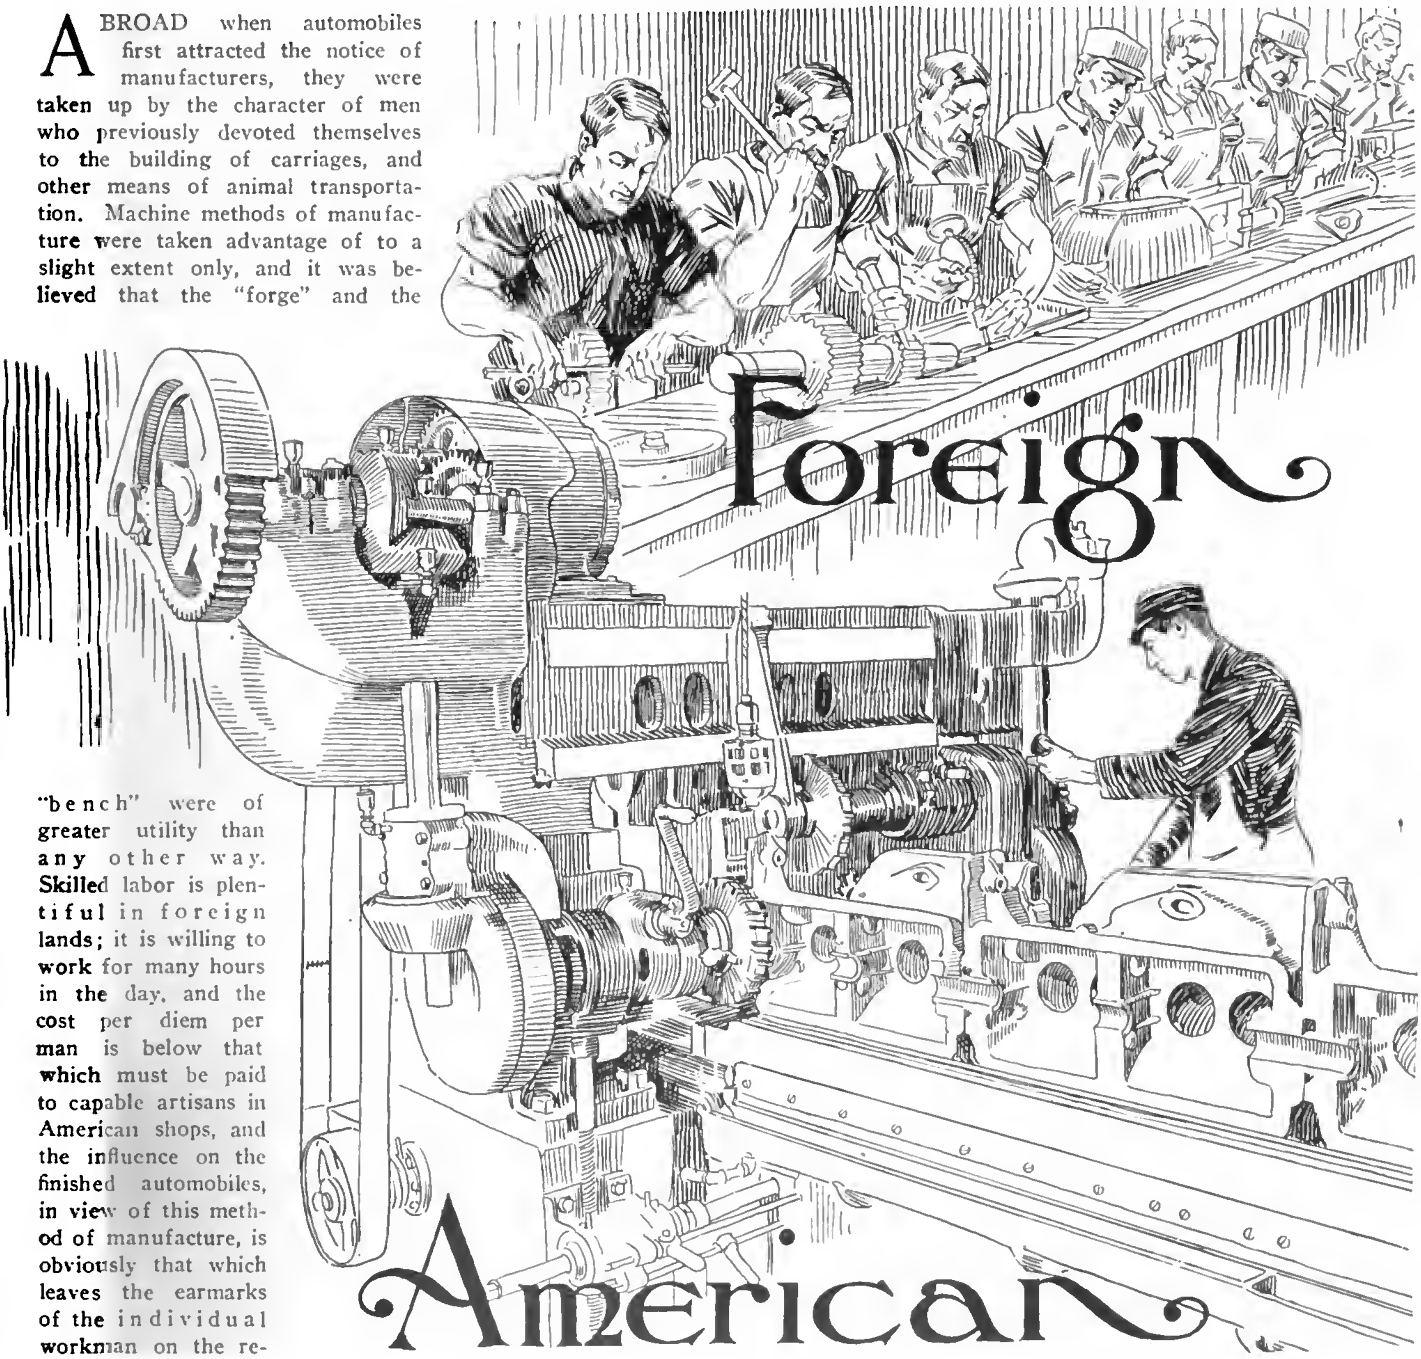
INDEX TO ADVERTISERS

XXII NEW YORK—THURSDAY, APRIL 28, 1910—CHICAGO No. 17

THE AUTOMOBILE

HOW PRODUCTION PROBLEMS ARE SOLVED

ABROAD when automobiles first attracted the notice of manufacturers, they were taken up by the character of men who previously devoted themselves to the building of carriages, and other means of animal transportation. Machine methods of manufacture were taken advantage of to a slight extent only, and it was believed that the "forge" and the "bench" were of greater utility than any other way. Skilled labor is plentiful in foreign lands; it is willing to work for many hours in the day, and the cost per diem per man is below that which must be paid to capable artisans in American shops, and the influence on the finished automobiles, in view of this method of manufacture, is obviously that which leaves the earmarks of the individual workman on the respective automobiles.



The finished product so made is at the expense of an unusually large number of man-hours, and the quality of the product, aside from the question of the material employed, is the net and direct result of the skill of the workmen employed. The total cost of these cars would be enormously high in America, because living wages are paid to the men who do the work, and in this country, in order to be able to satisfy all phases of the problem, dependence is put upon highly developed

Fig. 2—Battery of Fellow's shapers, which are substantially automatic, requiring but one man to keep them running

machine tools, under certain well-defined conditions of manufacture, thus eliminating the army of workmen, unusually long hours of labor, and certain other involved variables.

Despite the cheapness of labor as it obtains abroad, and the low price commanded for the materials used, the prices of foreign automobiles were found to be so high that they were regarded in this country as toys for the luxuriantly inclined. Experience, and the extension of output, tended to the lowering of the unit price of cars so made, but it was soon found that a popular level could not be reached, even when the workmen were urged to the point where a semblance of interchangeability of the parts is all that could be claimed.

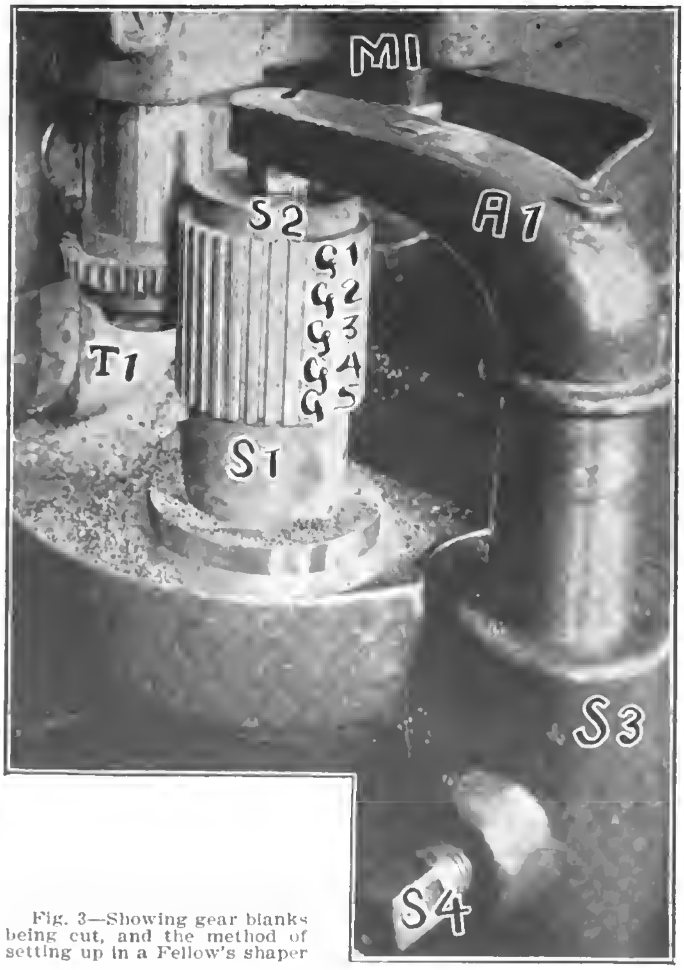


Fig. 3—Showing gear blanks being cut, and the method of setting up in a Fellow's shaper

Some of the earlier efforts in America were in replica of these foreign attempts, modified somewhat perhaps, by the influence which the machine tool methods of that time necessarily brought to bear. Under such conditions, even the American manufacturing situation left a trail of formidable difficulties, which had to be erased before it could be said that quality and price were as companions in the enterprise.

HERE WERE IMPORTANT MATTERS TO BE CONSIDERED

It was soon ascertained that interchangeability of the component parts of automobiles was not possible when a plurality of men were depended upon for co-operation in the process, nor did it matter if the men, severally, were skilled. No two men, however equipped with instruments of precision, are agreed as to the dimensions of given parts, although it is true that the amount of the disagreement is but slight in many cases. The difference is always sufficient to make it impossible to ship a repair for an automobile to a distant point, and feel that it will go into place without having to be dressed and fitted at

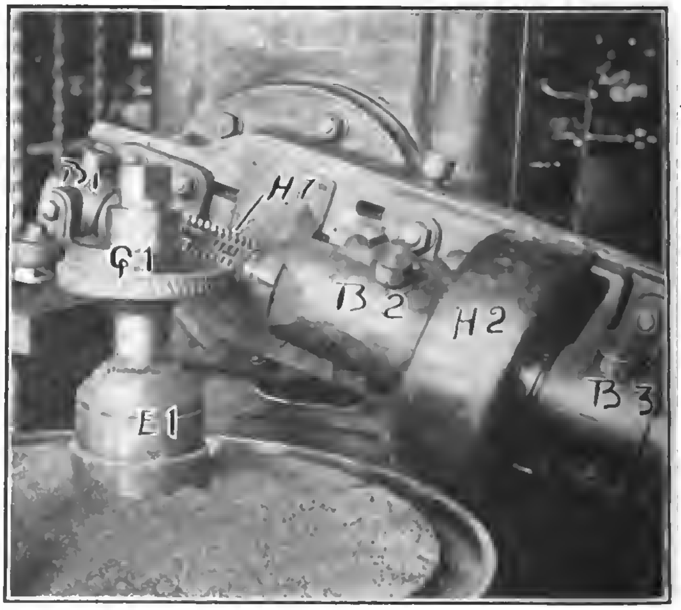

Fig 4—Hobbing machine working on the balancing gear of a Brush Runabout motor, showing continuous cutting operation

the expense of some skill on the part of the man who may do the work, and with a fair chance that the part may have to be centered in a lathe or in a grinder, and brought down to suitable dimensions, all things considered.

Interchangeability of the component parts must certainly be regarded as one of the important considerations, but a hand-whittled automobile can never measure up to this requirement, because the limit of tolerance will never strike within the range required. As an illustration of the exactness demanded, if the parts are to be interchangeable, it is only necessary to call attention to the great influence that a slight change in dimensions will have upon the fit of certain parts. It is well understood that a flywheel, for instance, if it is not securely adhered to the crankshaft will go adrift, and the damage it will do, in view of the energy it stores, is past reckoning. Let it be assumed that the flywheel is fetched up on a taper, which may be say, 3/16 of one inch per foot. Were the diameter of this taper to vary from a given standard by barely 0.001 of an inch, the flywheel would have to be moved up on the taper 1-16 of one inch. In other words, for every variation in diameter of the taper, the axlewise movement of the flywheel on the shaft will be 62 1-2 times the diametral variation.

The foregoing is not an unusual example of the differences which must be reckoned with when variations creep in during the manufacture of parts. That these variations will obtain, is an unavoidable certainty if a standard is not adhered to, and if each workman relies upon his own skill in the search for accuracy. In the absence of an arbitrary mechanical standard, there will be nothing but the plurality of standards of the respective operators; each one will have his own version of what he terms a neat fit, and there is nothing so surprising as the differences of opinion which actually do obtain as between men of recognized skill in this connection.

The quality of an automobile is not necessarily reflected in the design, as the same may be expressed in drawings. The engineer gives expression to his views when he supervises draftsmen, and they reduce the product of his creative genius into working drawings. The drawings serve for a certain utility purpose, if they are so clearly executed that they tell the workman what to do in definite language. It is a well established fact that while a one-inch round plug should go into a one inch hole, no one has ever succeeded in accomplishing the feat, and in practice an allowance must be made to satisfy an incongruous situation.

Limits of tolerance, if they are properly expressed upon the

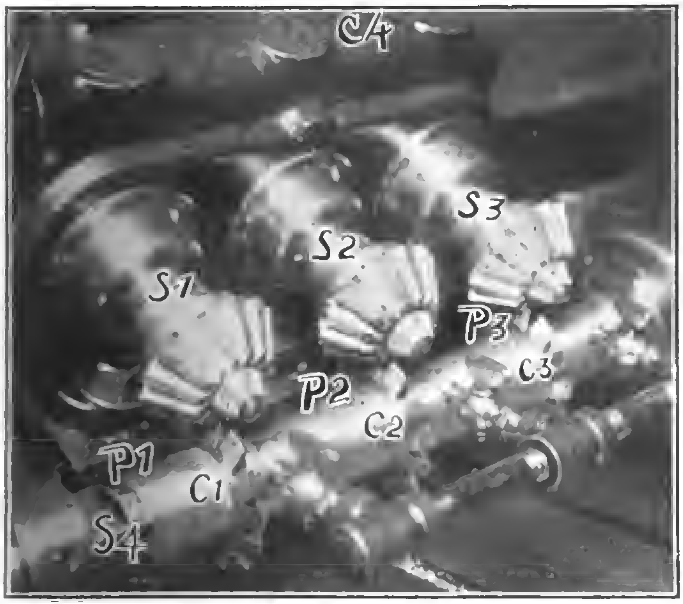

Fig. 5—Beveled pinions in a gashing machine with fixed cutters working three sets at one time

working drawings, tell the workman how much of an allowance he may be permitted to make, having in mind the necessity of so manufacturing the parts that they will satisfy the interchangeability idea. These limits must be varied with the diameters of relating parts, as for illustration, tbe practicable difference, considering a part with a one inch diameter, may be considerably less than the difference which will have to be instituted when the parts are say six inches in diameter.

This situation is so fraught with complication that the tabular values of the allowable limits of tolerance, require years of refinements ere it can be said that the interchangeable situation will be adequately represented, and the principle of operation is such that the algebraic sum of the allowances must be equal to zero.

PREDETERMINED INACCURACY PRESENTS THE RIGHT IDEA

From what has been said, a normal conclusion may be reached when it is decided to control the inaccuracies with the drawings in hand with which to execute the scheme of the designer, and the limits of tolerance thereon, which will tell of the allowable variations; the workman may then be permitted to proceed, but unaided by some further and scientific process, he cannot possibly execute the design on a basis of interchangeability. If it

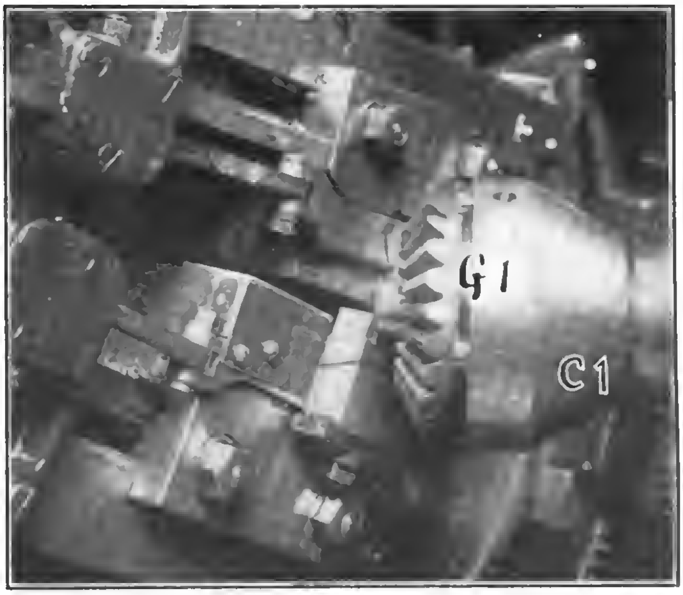

Fig. 6—Gleason planer profiling bevel gears after they have been gashed in the milling machine

is admitted that no two workmen can measure a given diameter of a part and arrive at the same conclusion, this is equal to admitting that no two workmen can make a given allowance in departure from a neat diameter. It is just as difficult to machine a part down to some variable from a fixed diameter; as it is to execute the work in the absence of any allowance at all, unless it is true that the allowable variation is several times that which should obtain on a basis of the interchangeability of parts.

Even with the accurate machine methods, as they obtain at the present time in America, limits of tolerance must be taken advantage of in order to satisfy the situation. The machine process has for its basis the quick and

Fig. 7—Double spindle vertical boring equipment with a special fixture, working on Regal cylinders

substantially accurate method of production so contrived that the variable, whatever it is, will be the same in all the parts produced, no matter how many men are employed, or which one of them performs a given operation.

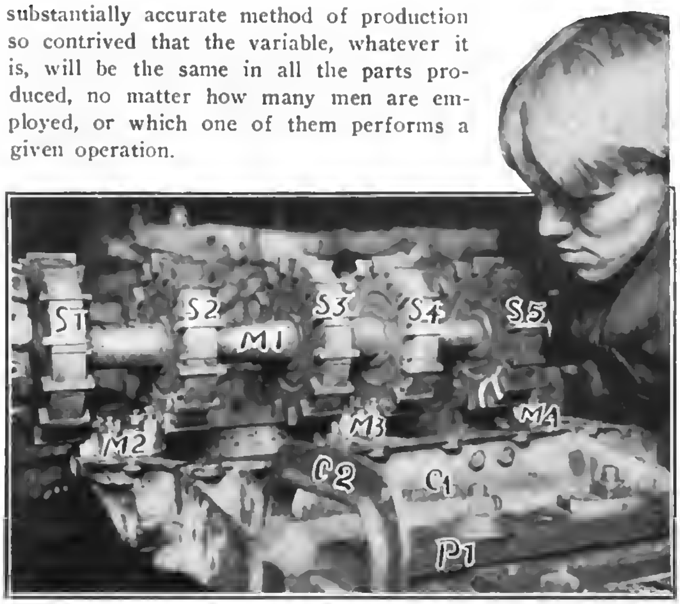

Fig. 8—Regal crankcase having main bearings ended off by means of a straddle mill set on a large milling machine

What the American makers of automobiles started out to do was to reduce the cost of automobiles without reducing the quality thereof. They were compelled to consider the higher cost of American labor, and the use of good material naturally had a further influence on the cost, with an upward trend. The very fact that American labor will take the initiative when it is left to its own devices constitutes a danger, and the personal equation represents a serious situation, which, like the inaccuracies of process, must be subdued and controlled.

DRAWINGS ARE NOT USED TO BUILD AUTOMOBILES

In the execution of the plan of the designer, since no two workmen can be depended upon to arrive at the same conclusion in measuring the dimensions of the parts, it is a self-evident fact that drawings are valueless for the purpose; what they are for, and why they are made, is quite another story. Workmen, in order that they may be utilized under conditions of rapid production, are given the required special machine tools to operate, and the parts to be machined are locked into fixtures, which are so contrived that they serve as jigs, and the cutting processes, whatever they may be, are done by means of special tools, which are sharpened and sized in a tool room by men who are schooled in the art. Under such conditions, if a workman is required to drill say four holes in the flange plate of a cylinder, all he can do is to mount the cylinder into a fixture in the one way that it will go, lock it into place, and with the drill given him, which is properly sized before he gets it, drill the four holes just where they register, by means of the jig plate, which is a part of the fixture.

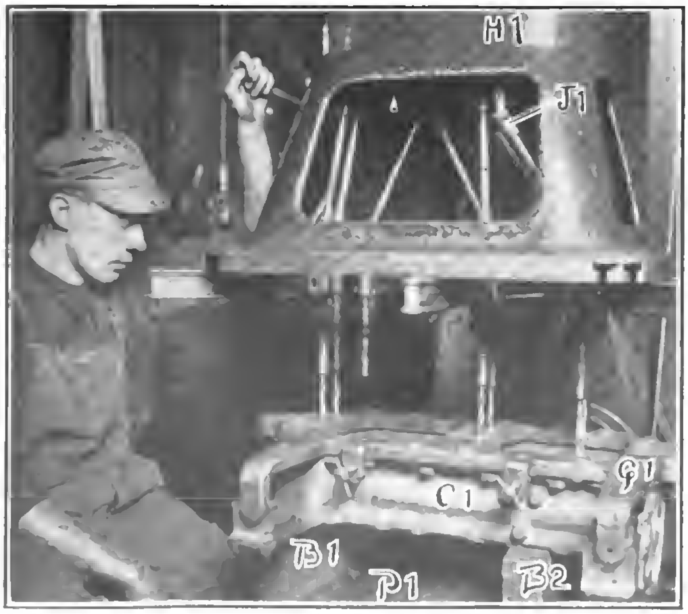

Fig. 9—A multiple spindle drill having 16 spindles, some of which are engaged on a Regal crankcase, guided by a jig

What the drawings are for, then, is to guide the toolmakers who produce the special fixtures, jigs, gauges and tools. If there is any inaccuracy it is that which will come from mistakes made hy the toolmaker specialists. By a system of checking in the

Fig. 10—Multiple spindle drill in the Regal plant working in conjunction with a jig fixture, reaming connecting rods

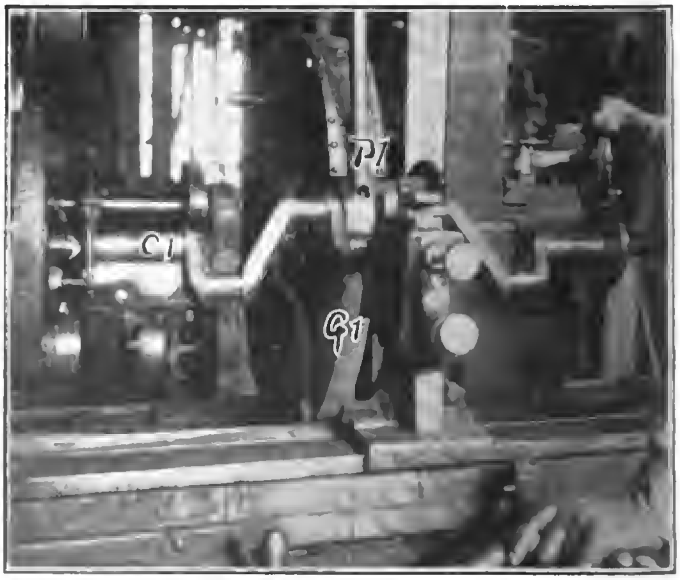

Fig. 11—Landis Grinder in the Regal plant finishing crankshaft bearings to make them round and true

tool room, all such mistakes are likely to be discovered. Even if a mistake should be made in the production of a fixture, it does not necessarily react to disadvantage, because every automobile produced will have this mistake in it and the parts will be interchangeable notwithstanding its presence. It is perfectly feasible to standardize a part, even though departure may be made from the drawings, the difference, if it creeps in during the production of the tools, may be tolerated if only it does not interfere with the manufacture and assembling of the products, nor is it far-fetched to reach the conclusion that a mistake from the toolmaker's point of view, ceases to be such.

DIVERS MAKERS FURNISH A WORKING EXAMPLE

If it is understood that the accuracy and speed of production is dependent upon the process and the machinery equipment, rather than upon the skill of the workmen and other like considerations, the reader will be ready to go into the shops and review the processes involved and employed, in order to learn why it is that American automobiles may be produced in the large numbers that they are, and be the better for it. The very facts reviewed thus far reflect quality as the companion of

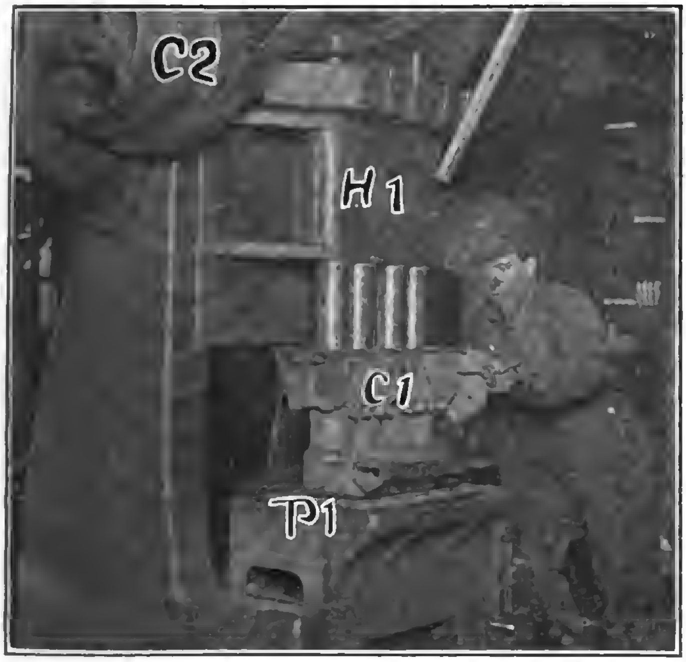

Fig. 12—Special vertical boring mill with 4 spindles so spaced as to finish Everitt en bloc cylinders simultaneously

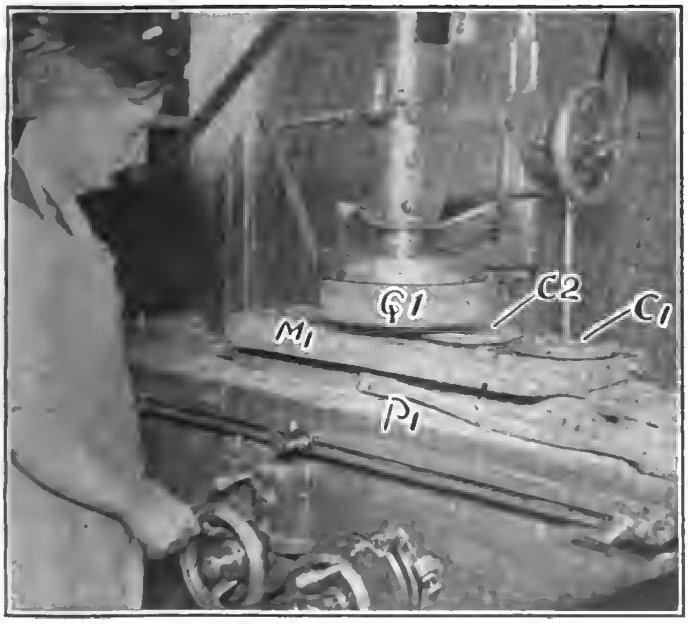

Fig. 13—Flat grinder with magnetic chuck working on hand-hole plates in the Excelsior plant

quantity, and the trend of the theme has for its foundation the fact that interchangeability of parts, and harmony in the relation of the components, cannot be the child of the individual uncontrolled efforts of men however skilled they may be.

Multiple operations are taken advantage of to a marvelous extent, and it is of course true that a machine tool, if it will turn out five parts instead of one, will do the work of five men

Fig. 14—Piston ring grinder with magnetic chuck finishing piston rings for Excelsior motors

at the cost of one. On the other hand, if it will do the work of one man with sufficient accuracy for its intended purpose, the same accuracy will obtain for all of the operations.

The special machine tools which are designed for multiple operations are so made in many cases that they perform their respective functions continuously. Turntable platens in some cases permit of setting up work to be done at one point on the platens, while work is being done by the tool at some other point thereon.

THE AUTOMATIC PRINCIPLE IS TAKEN ADVANTAGE OF

In divers examples, the multiple operation idea fails to satisfy the needs of the situation, and automatic machine tools are introduced in order to expedite work. Fig. 2 shows a row of Fellow's shapers which are excellent representatives of this idea. This equipment is in part representative of the process utilized in

(*Continued on Page* 808)

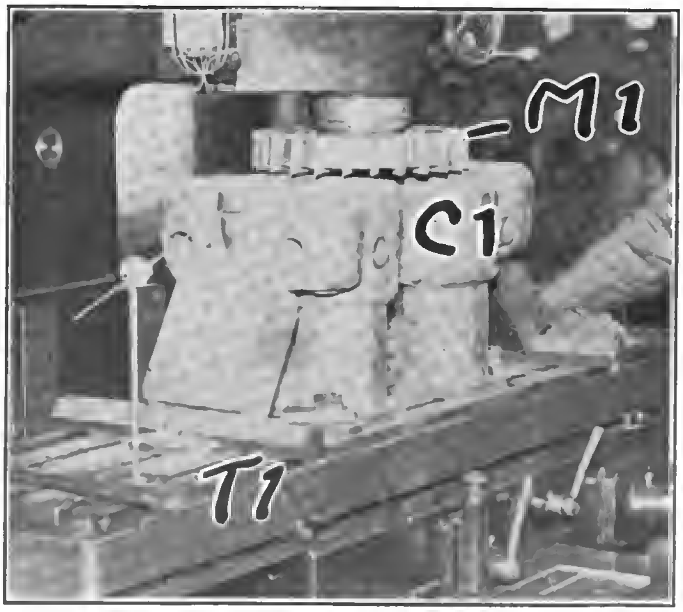

Fig. 15—Cat head on a No. 4 vertical Cincinnati mill finishing 4 Excelsior cylinders at one time

BEST MEANS FOR DUSTPROOFING THE HIGHWAY

By MARIUS C. KRARUP

ONE of the objects of this article is to contribute to the success of the good roads agitation by pointing out a systematic method for making information on the subject of dustless roads applicable to any given set of requirements. Incidentally, it will appear, by this method, that the available information is insufficient for this purpose and in need of being supplemented.

A mass of scattered literature has been accumulated, here and abroad, during the past ten years, on the subject of improved, modern road construction and maintenance, with special reference to the damage done to the best roads of the earlier types by rapid automobile traffic, to the means for avoiding this injury to the roadbed and, most particularly, to that symptom of destructive road wear which is in itself a nuisance and a source of disease and expense: The dust.

But this literature, expensive as it is, must be read with pen in hand and copious taking of notes, if the reader shall avoid feeling himself driven by the strong current of events and opinions toward the acceptance of certain conclusions which after all may not be fully justified or applicable to the practical case of contemplated road improvement with regard to which he seeks enlightenment. On the surface of all records of recent achievements in road improvement there is written a strong testimonial to the superior qualities of the new-built macadam road, protected against subsoil water by drainage and against rain and detrition by immersion of its materials in a matrix of refined coal tar. Durability, long-time economy and freedom from dust, noise and vibration seem to be demonstrated as more fully combined in this type of road, properly built, than in any other. Built for heavy traffic, it should, according to widely accepted data, offer decided advantages over granite setts, and, built for light traffic, it should prove cheaper than an ordinary graveled or stoned country road, by reason of reduced cost for maintenance. In the light of plain engineering, which assumes that the higher first cost may be defrayed by means of a loan drawing 4 per cent. interest or by some other legitimate financial operation on the part of the community which is to pay the cost, there seems to be no reason why roads of any other type should be built. The freedom from dust is a gratuitous addition to its advantages. This conclusion, however, is flatly contradicted in practice. The measurement of road values in absolute dollars and cents is not accepted, partly because the values considered are always prospective, but also for other reasons. Political, legal, financial, economical, engineering and labor conditions conspire to render the stupendous American road problem one of the most complex with which any man can grapple. And little has been done to simplify it.

Only those who refuse to recognize road improvement as urgent have a simple solution—this of doing nothing or as little as possible. Their position may be similar, in some respects, to that of the "common people" of whom Lincoln said, that God must like them, since he made so many of them. They refuse to be stampeded into paying, wholly or in part, for building an expensive road where only a dirt track is needed for occasional travel, in their judgment. In the rubbing and jostling of opposing interests, they represent properly the thousands of miles of roads which should not be improved by public means, because they carry little traffic and would not carry much more traffic of economic value if they were improved. In the great division of the road problem, as to where roads should be improved and how roads should be improved, they represent the questions under the first branch as intelligently as anybody, but trespass, of course, on the second, as all conservative interests do when roused by opposition. When they are in error in a financial comparison between the final costs of one type of road and a better one, and choose the type involving lesser risk rather than the one promising most economical results, it is fair to presume not that they are temperamentally opposed to progress, but that no convincing argument has been placed before them, or that they have observed many discouraging cases within their own municipal experience, where incapacity or corruption saddled a heavy burden of maintenance upon a community through the miserable execution of excellent plans. From this point of view, the problem of the good roads movement becomes largely the problem of establishing a reliable system of guarantees for the proper selection of the most advisable type of road in each case, for the proper workmanship in its construction and for the maintenance of the road for a definite period, such as twenty years. Often the legal status interferes with the establishments of such guarantees as alone would satisfy hardheaded objectors. Frequently local ordinances relating to the debt limits prevent the financing of a project which is meritorious only if financed with thorough provisions for continued maintenance of the values which it is to establish.

The questions of proper financing and of proper guarantees are now admitted by several authoritative good roads advocates to constitute part and parcel of the problem of comparative road economy. Road values, as pronounced by the road engineer, are consequently subject to modifications, accordingly as the financing and the guarantees actually available are more or less removed from perfection.

The Romans, of old, removed the questions of maintenance cost and organization by building deeply founded, broad-based stone roads to last for ages without repairs, and they settled the question of location by military edict and the difficulty of high first cost by employing serf labor, but in a self-ruling State composed of self-ruling communities, the majority of voters must somehow be convinced that they get value, and not only that the intangible and faraway abstraction, known as the State or the larger commonwealth is benefitted. To get order out of chaos and indecision under democratic institutions, a strong, convincing educational campaign is admitted by all to be a requisite, but in the matter of dustless road construction there is at present only a mass of road engineers' notes and data, and to simply hurl this at the heads of the unwilling does not seem to constitute the best method of persuasion.

There is a still more important limitation to the road engineer's dictum as to the relative values of different kinds of roads. More important, at the bottom of things, than any distinction as to where a good road is justified and where a makeshift road is more sensible and more important than any consideration of difficulties in financing and guaranteeing of the work, the question whether any proposed type of road construction admits of procuring materials and labor within the boundaries of the community which must pay for these materials and labor, looms up as one which the responsible members of the communities are justified in considering in the very first line. It is related of MacAdam that he took great pride in getting much of the road construction work for which history has honored him, done by "old men and women," whose time would have been wasted in idleness, if the road building enterprises had not provided an occupation for which they were as well suited as younger persons. This had special reference to the breaking of stone at the roadside, and is, of course, inapplicable to modern American conditions, but the principle that work which is simply added to the sum of work ordinarily done in a community, and the wages for which are paid to a class of workmen who practically spend all their earnings in the local purchase of life's necessities and deposit possible savings in local banks where they become available for industry and commerce, that such work in reality costs nothing, while adding to the wealth of the community by producing a value or a luxury which is wanted.

is a tenet of social economy of which the engineer's estimate takes no cognizance, but which is honored in the decisions of many local authorities, often in contravention of ordinances which provide that the lowest responsible bid shall be accepted. And it is still a peculiarity of road work that it appeals largely to a class of workmen who have no liking for steady labor, but who are inoffensive citizens willing to work hard at intervals in order to gain leisure for other periods. Every town and village seems to have its contingent of persons who subscribe to this easy philosophy, and in the economy of the community they take the place of MacAdam's "old men and women," whose work for the improvement of the roads he considered a clear gain.

It is probably clear that acknowledgement of the claims for the greatest possible local participation in road improvement work does not restrict the usefulness of the road engineer, but on the contrary enlarges the sphere of knowledge on his subject of which he must possess himself in order to become indispensable and thereby raises his occupation to the level of a distinct branch of civil engineering, not easily to be mastered except as a specialty and life vocation.

And the activities of the great national construction companies could hardly be enlarged and diversified by any safer means than by kindling local interest in road improvements through a broad acknowledgement of the active part which the locality may often assume in the production of the materials and the labor required for the work. An example is afforded in the possibilities which exist for establishing a plant for the refining of coal tar in every town possessing gas works, it being admitted and urged by road engineers all over the civilized world, no less than by the construction companies, that the highest durability of bitulithic roads and of every road which is improved by means of coal tar treatment, depends upon obtaining perfectly definite and known grades of coal tar for the work, while at present the shipment of these grades from distant production centers represents a considerable addition to the necessary cost in this class of road-building.

Still another very large factor obstructs the probabilities for having the road engineering data, which have been compiled during the past ten years, applied in a simple and direct manner and on a purely financial and mechanical basis, to every projected road improvement enterprise in this broad land. As above referred to, these data relating to the testing out of many and diverse processes for meeting the demand of the age for lasting and dustless roads, converge in their recommendations of coal tar products as indispensable for true economy, with various residues of asphaltic petroleums the only competing materials, except in special localities, as in California, where crude petroleum as such, locally produced and very rich in asphaltum, also competes, or perhaps predominates, owing to a favorable climate.

The question arises at once whether the national production of coal tar is or can be made to equal in quantity the vast amounts which would be required, if the conclusions arrived at by the authorities on road construction in the United States and Europe were to be unanimously accepted and acted upon. Only relatively short stretches of dustless roads have so far been built, mostly suburban in this country, though both France and England have treated or rebuilt a considerable mileage of country roads, largely with special preparations of water-gas tar, but showing a leaning recently in favor of refined coal tars. It is a foregone conclusion that the price of coal tar will rise steadily, if the agitation for dustless roads achieves a true popular success in this country. It seems more than doubtful if a town with gas works will be able to supply the material in sufficent quantity for its own outlying streets and roads, as well as for the other industrial purposes, such as roofing and the production of dyes, for which coal tar is used. And if a positive shortage is bound to result before the dustless road, accomplished by means of

(*To be Continued.*)

ELGIN GUARANTEES FUND FOR BIG RACE

PROGRESSIVE citizens of Elgin, Ill., have guaranteed a fund of at least $15,000 to make possible the holding of an automobile road race near Chicago this year. There is strong reason to believe that the event may assume the character of a national stock chassis contest since the Automobile Club of Lowell, Mass., has decided not to hold its authorized event.

M. M. Cloudman, merchant; W. W. Willson, editor and Fred W. Jenks, theatrical manager constituted the committee of Elgin business men who succeeded in securing the promises of financial support from the city of watches and butter and as a result of their success along this line, enthusiasm runs high in Elgin and the Chicago Motor Club is very complacent.

The course that has been discovered near Elgin is an irregular polygon with two long sides and is about eight and a half miles in circumference. Starting at the northeast corner of the course, the route follows the old McQueen road in a generally northwesterly direction and passes over the only hill of any importance about midway between West Elgin and McQueen. This hill is approximately 12 per cent gradient, but is short in length. On the other side, the descent is easier and when the route turns southward, just this side of McQueen, the road level is practically the same as it is at West Elgin. The south leg is short and the turn at Udina brings the contestant around to the east where the road stretches away almost straight and flat as a board as far as West Elgin. South from the course the wonderful, rich Illinois prairie, black and deep with the fatness of the earth, extends as far as the eye can reach. The last leg of the course is northward to the point of beginning.

In some respects the Elgin route possesses more natural advantages than any similar track in the country. There is not a dangerous spot in the eight and a half miles and the turns can be banked with little effort so that high speed will be possible.

Elgin will donate steam rollers, horses and working apparatus as well as the services of the road supervisors, who have volunteered to take charge of the job. It is estimated that it will cost $8,500 to put the course in racing shape and the latest reports indicate that at least $16,500 will be raised. This amount is well over the tentative figures suggested by President David Beecroft of the Chicago Motor Club when he first considered the advantages of the Elgin course.

The discovery of the course is credited to Frank Wood, manager of the Chicago Knox branch and after a careful inspection by the C. M. C. the matter was laid before the business community of Elgin with a suggestion for co-operation. The advantages to the locality were so patent that the movement had instantaneous growth and vigor and the progressive city that "Makes the Whole World Tick" seized upon the opportunity presented.

Definite plans for the initial contest have not been made so far, but as soon as the final word is given, the scope of the plans will be considered in detail. The situation is full of possibilities as the schedule for big racing events about Chicago have been in a doubtful state for some time and more uncertainty looming up for the future.

The new course has excellent transportation facilities. It is only about thirty-eight miles from Chicago and is reached by rail and trolley with practically continuous service. On big race days immense crowds could be easily handled to and from Chicago.

The idea of constructing this course seems to have met spontaneous approval from everybody concerned and all indications so far seem to point to realization of the hopes of motordom.

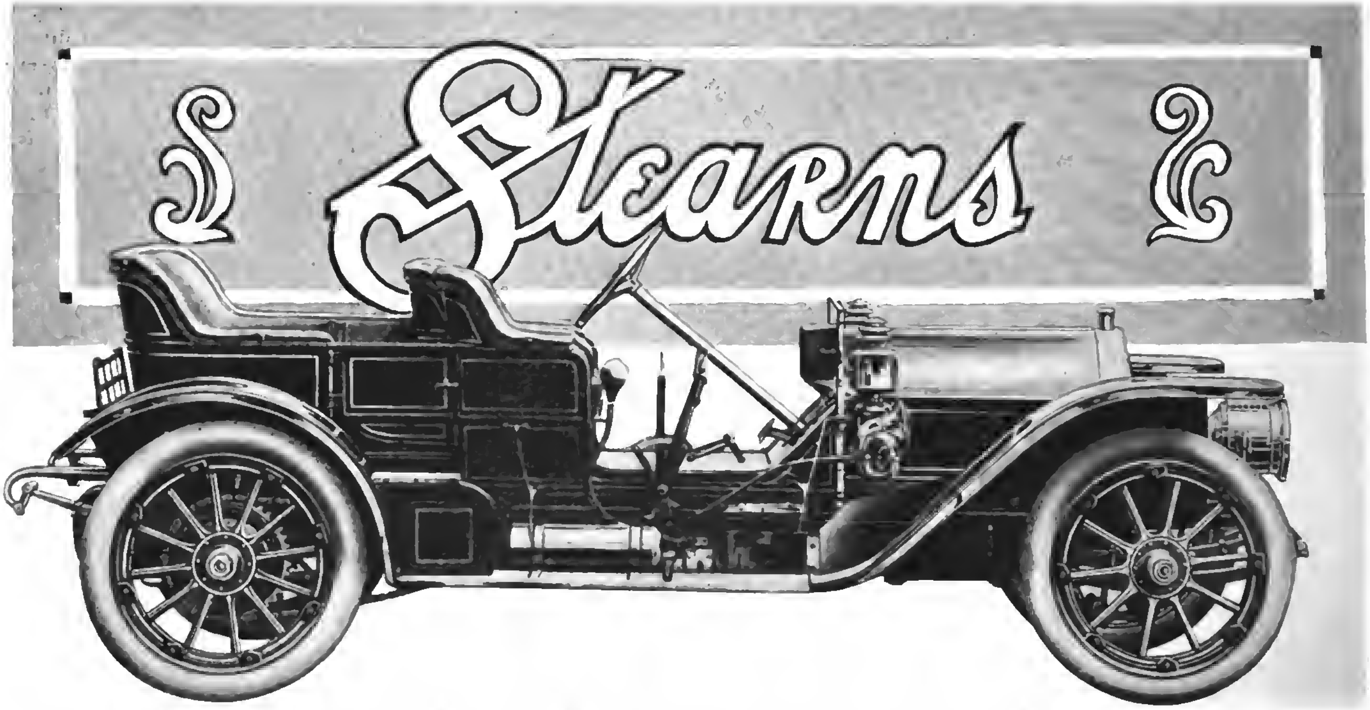

Fig. 1—Stearns 30-60 with a seven-passenger side entrance tonneau of the side chain drive design, showing ample room for the front seats as well as in the tonneau

THIS make of car as produced by the F. B. Stearns Company, Cleveland, Ohio, is offered to discriminating buyers in two models, the smaller of which is known as the 15-30, and the higher powered car is represented as a 30-60. Taking the model 15-30 as the subject for the moment, it may be described with a touring body as a car which seats five and sells for $3,200. The motor is of the four-cylinder type, with a bore 4 1-2 inches, and a stroke of 4 5-8 inches. The cylinders are of the T type, with the valves located on the left-hand side. The cylinder design is that designated as en bloc, utilizing the four-cycle principle. Lubrication is by splash, with a gear pump which is used for the purpose of maintaining a constant level and circulating the oil on a basis of profuse lubrication. A notable feature of this system lies in the control of the oil supply, which is by means of external leads; they are well designed, stout, and get-at-able. The gear pump is driven by a spiral gear.

Cooling is with water, circulated by a centrifugal pump, utilizing a cellular type of radiator of neat design for the purpose of absorbing the heat out of the water, and the air circulation is maintained at the desired rate through the use of a six-blade fan which is driven by a belt.

Ignition involves the use of a magneto, and an auxiliary means, the Bosch dual system is employed, and as is well appreciated by users, they are enabled to start with all the facility which is offered by a battery and coil, and to switch over to the magneto with its attending advantages at will. If, in the course of time, the magneto should become deranged, the auxiliary portion of the system is sufficiently complete in itself to serve the purpose. Carburetion is by means of a Stearns design of carbureter, in conjunction with a gasoline tank of ample capacity, and the gasoline flows to the carbureter impelled by pressure in the tank.

Coming down to the most pertinent of the mechanical features, the clutch is of the latest dry plate type, using steel on fireproof fabric, thus affording a soft but positive action,

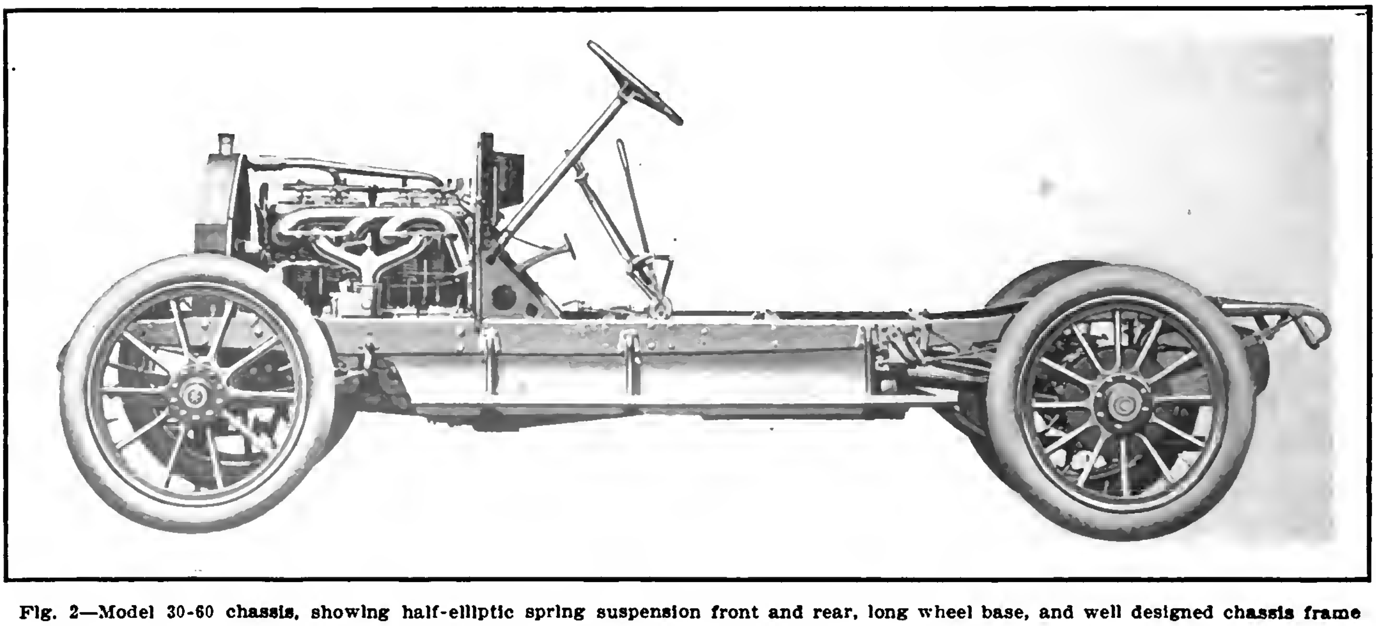

Fig. 2—Model 30-60 chassis, showing half-elliptic spring suspension front and rear, long wheel base, and well designed chassis frame

and other advantages, which were brought to prominence during the last year. From the clutch to the transmission gear the mechanical features are worked out to a nicety, and the gear itself is of the selective sliding type with three forward speeds and reverse. The transmission connects with a shaft drive, utilizing a torsion tube, and the rear axle is of the full floating type.

Bearings are of the anti-friction type at every point of the slightest moment. The crankshaft revolves on annular type ball bearings, of which there are three, and the same may be said of the camshaft, clutch spindle, transmission gear and rear axle. A thrust bearing is used in the clutch. The hub bearings for the front and rear wheels are of the roller type, self-sustaining as to thrust, and capable in the radial plane. Plain bearings are used in the steering knuckles.

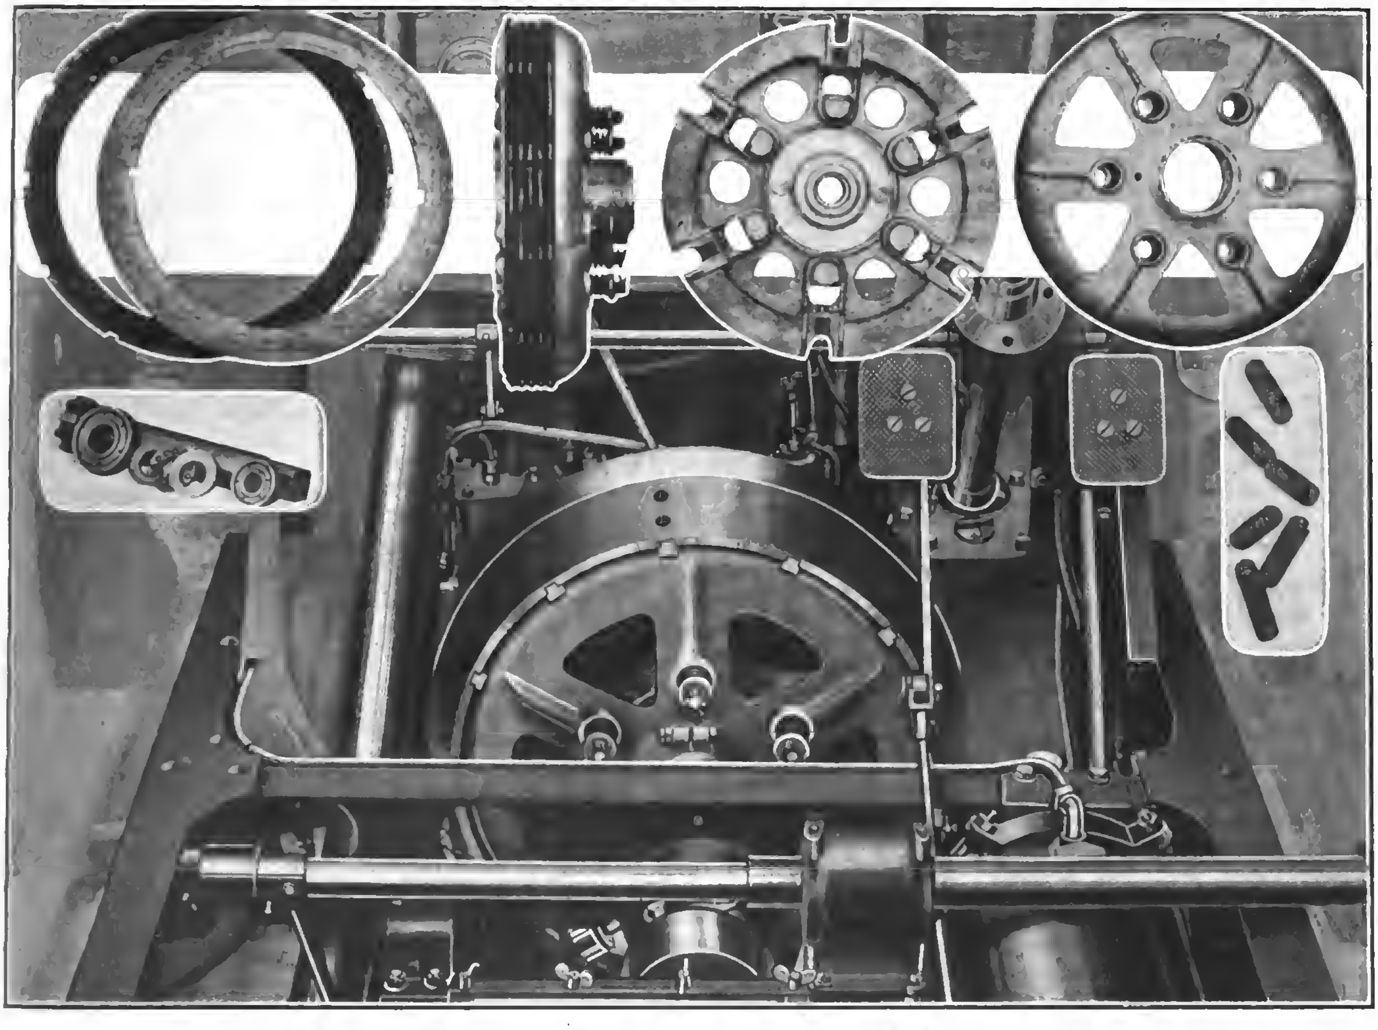

Fig. 3—Details of design and construction of the Stearns dry plate clutch, showing strength and stability throughout

The wheelbase of this car is 116 inches, with a 56 1-2-inch tread, and the wheels are fitted with 34 by 4-inch tires front and rear. The suspension of the chassis frame is of the semi-elliptic type of springs in front, they being 2 inches wide and 39 inches between eyes. The rear springs are three-quarter elliptic with 2 1-2-inch plates, and the span is 51 inches.

The front axle is of the I-beam section, forged without welds. and suitably treated to bring out the kinetic properties of the metal. The rear axle is a construction involving a double branch I-section with a differential gear and bevel drive suspended between the bows of the branching members, the idea being to eliminate the troubles which are normal to inferior live rear axles, which are manifest by sagging and disalignment generally. The wheels are fitted with Continental demountable rims, and the construction throughout is on a high engineering plane, using alloy steel at every point demanding high ability, and special heats in other grades of steel to induce a proper measure of harmony.

CHARACTERISTICS OF THE 30-60 STEARNS MODEL

This car, fitted with a touring body, with a capacity for seven persons, sells at $4,600. The motor is a four-cylinder, water-cooled type of the four-cycle genera. The bore of the cylinders is 5 3-8 inches, and it rates with the long-stroke type of design because the stroke is 5 7-8 inches. T-type cylinders are used, with the valves located on the left side, cylinders cast in pairs, and the design is conspicuous for the symmetrical arrangement of the components, a certain get-at-ableness embodying the idea of quick dissembling in the event it becomes necessary to make an investigation in an extended way for any purpose.

Lubrication is by splash, but the oil level is maintained at the right elevation through the good office of a gear pump, which is driven by a spiral gear, and the oil ducts are externally placed, rigid in their design, and open to inspection at will. The water circulation is by means of a commodious centrifugal pump, which is gear driven, and a thoroughly capable cellular type of radiator, in conjunction with a six-blade belt driven fan, co-operated in the cooling process. A conspicuous feature of the Stearns motor work, which is carried into the cooling system, is the character of the water piping, etc., in which the earmarks of capable coppersmiths may be readily observed.

Ignition is by Bosch magneto, hand controlled, with an auxiliary system of Bosch characteristics. A Stearns carbureter is responsible for the character of the mixture.

A discussion of the pertinent mechanical features of this model will bring out the use of a dry-plate clutch, with steel on fiber, particularly harmonious details of the control system as pedals, etc., and passing back to the gear-set discloses a four-speed selective sliding gear. It is claimed for this four-speed system that it induces economy in the operation, helps in the accelerating process, and has the virtue of reducing tire depreciation, because by the use of four speeds in a car of this size it is possible to apply the power of the motor progressively and by such graduations that a harmonious relation will obtain between the tractive ability between the point of contact of the wheels and the exertion of the motor.

The transmissions system involves a shaft drive, but at the option of the purchaser side chains are furnished instead. With a shaft drive a capable torsion tube is employed, whereas if the side-chain drive is selected solid radius rods are responsible for the accuracy of the location of the rear axle. In the shaft-drive type of this model a full floating rear axle is employed.

The crankshaft is equipped with three annular type ball bearings, the camshaft with four, and the clutch spindle gear set and rear axle are also fitted with annular type bearings. It is worthy of note that the thrust of the clutch is taken by a suitable anti-friction bearing. The front wheels are equipped with roller bearings, but the steering knuckles and steering gear have ball bearings. From what has been said, it will be observed that the bearing situation is well in hand.

The wheelbase of this car is 123 inches, with a 56 1-2-inch tread. The wheels are fitted with Continental demountable rims as regular equipment, and the tires are 36 by 4 1-2 inches front and rear. The front springs are semi-elliptic, with 2 1-2-inch plates, and the span is 41 1-2 inches. The rear springs are also semi-elliptical with 2 1-2-inch plates, but the span is 52 inches. The front axle is I-section of a highly kinetic grade of steel, forged in one piece. and suitably treated. The brakes, of which there are service and emergency, are fitted in the rear wheels; the service brakes are worked by a foot-pedal, and the emergency brakes are actuated by means of a side lever. The service brakes are of the contracting design, but the emergency brakes are of the expanding type. The chassis frame is pressed steel of excellent proportions, the further details of which will be rendered at once apparent by glancing at the illustrations here afforded.

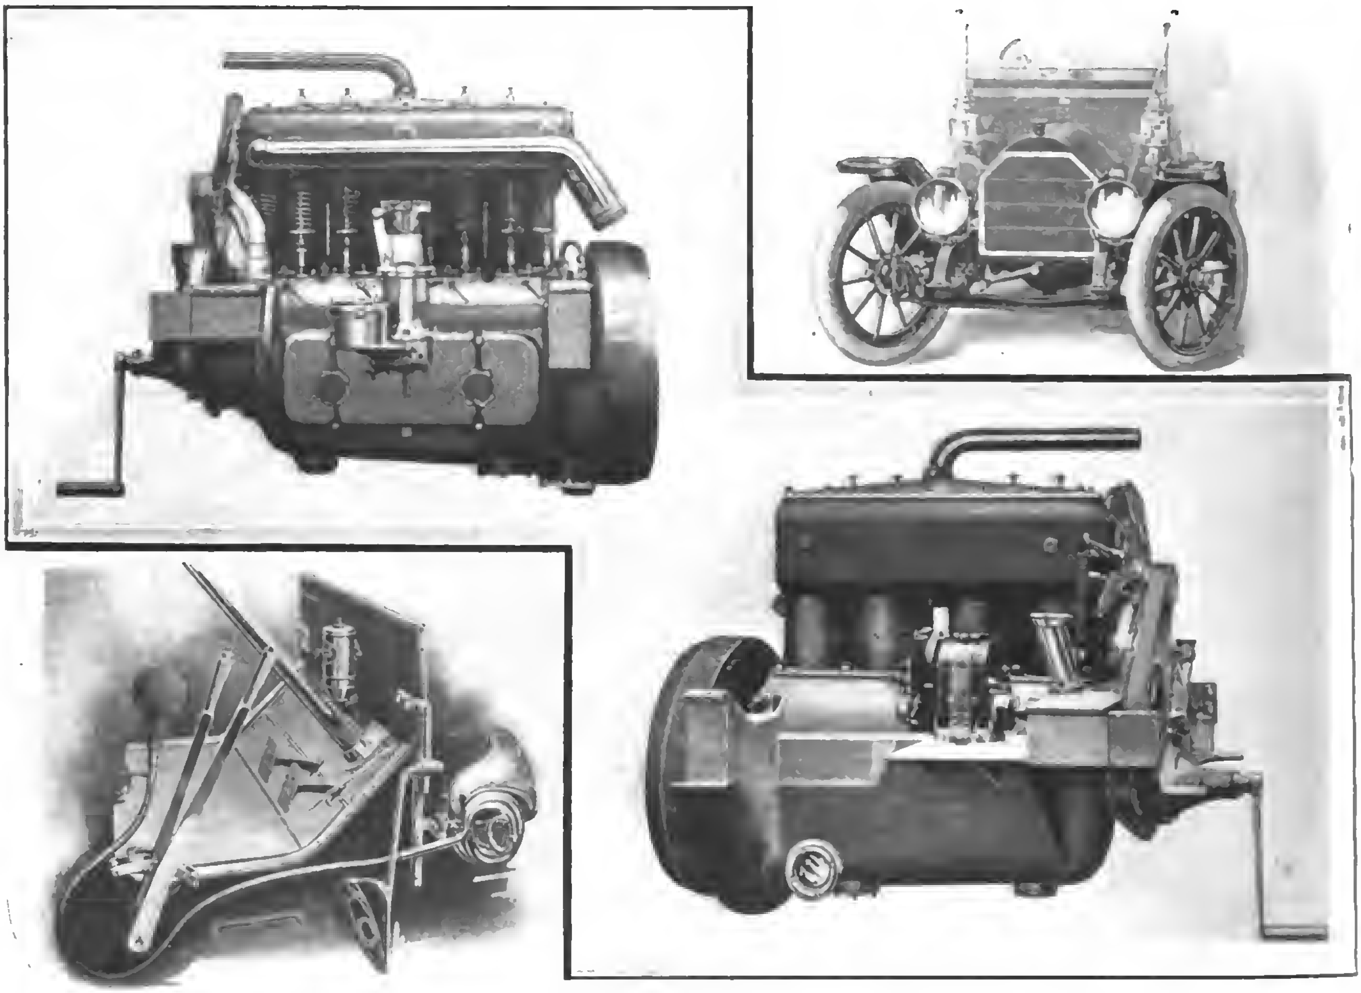

Fig. 4—Two views of the 15-30 motor, showing the carbureter on the left-hand side, and the magneto on the right. Two views of the chassis, one of which presents the characteristic Stearns front and the other depicts a clean dash

GENERAL CHARACTERISTICS OF STEARNS AUTOMOBILES

Carburetion has the virtue of having been used in previous years, and it is claimed by the designer that it has the advantage of two carbureters fed from the same float chamber, and actuated by the same throttle lever. It is well appreciated by autoists in general that extreme flexibility is difficult of realization when a single nozzle is employed. The relative sizes of air and gasoline passages are so proportioned that the mixture, considering the power required, is in substantial accord with power variations as they are indicated by road conditions and speed.

There are many points of refinement in relation to the power plant such as might be enlarged upon advantageously, as. for illustration, in the 15-30 the character of the block casting is up to a high standard. It is a perfectly symmetrical shape with a smooth and agreeable exterior, but passing beyond the question of mere appearance, it is to observe that the walls of the casting are uniform, bunching of metal is obviated, shrink holes are not prone to develop, and in the foundry in view of the large top opening, gases are permitted to escape most readily, and wasters are therefore avoided. The top cover being large. permits of

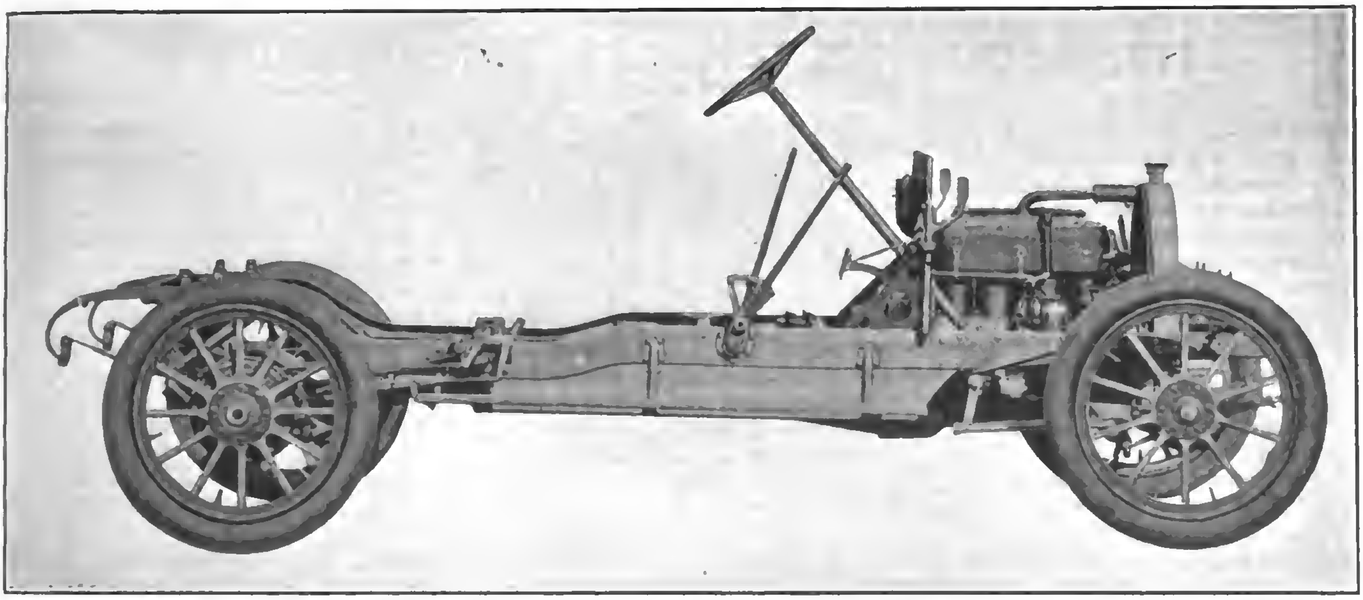

Fig. 5—15-30 chassis with double drop frame, three-quarter elliptic rear, and half elliptic front suspension

getting at the domes of the respective cylinders, and the volume of water available is such that cooling problems do not have to be coped with.

Passing back to the clutch for a moment, it will be observed that the dry plate members are sandwiched between a pair of capable master plates, and pressure is applied by means of six relatively light but live springs. Should the spring pressure be less than that desired by the owner of the car, he is offered the facilities of adjustment of the springs up to the limit of his own personal inclination, but should the springs press harder than the situation demands, the tendency to fierceness in the action of the clutch may be eliminated by the simple expedient of reducing the spring tension. The thicknesses of the clutch members are sufficient to take the torsional effort of the motor, and to accept resistance offered by the car as it negotiates road conditions, without undue surface pressure at the splines, so that the clutch engages and disengages readily, and undue wear on the pressure faces is done away with.

The chassis frame is stoutly braced in a lateral plane, and a cross-bar just back of the clutch is firmly anchored at its ends, and is so designed in point of strength as to present a neat appearance, evidences of strength, and to take the thrust without backing off so that the movement of the foot pedals is not reduced in effectiveness to the slightest degree.

The general appearance of the Stearns cars is enhanced because of the shape of the chassis frames, and the side entrance in both models is wide, comes well in front of the mudguards, and the height of the running boards is up to standard carriage practice, so that entrance and egress is on the most comfortable basis possible in automobile work. It is in matters of refinement such as this that the company has given much thought, and, considering the excellence of the general design, use of fine materials, character of the workmanship, etc., the reputation of the cars has expanded to excellent proportions.

From the point of view of safety in service, the straight line design of the cross and drag links, considering the quality of material and workmanship used, goes to show that this phase of the problem has been adequately attended to. The steering wheel and the method of its construction lends further promise to safety, and the relation of the driver in the seat to the steering wheel, foot pedals, side levers and other means of manipulation is that which has been found to be natural and efficacious.

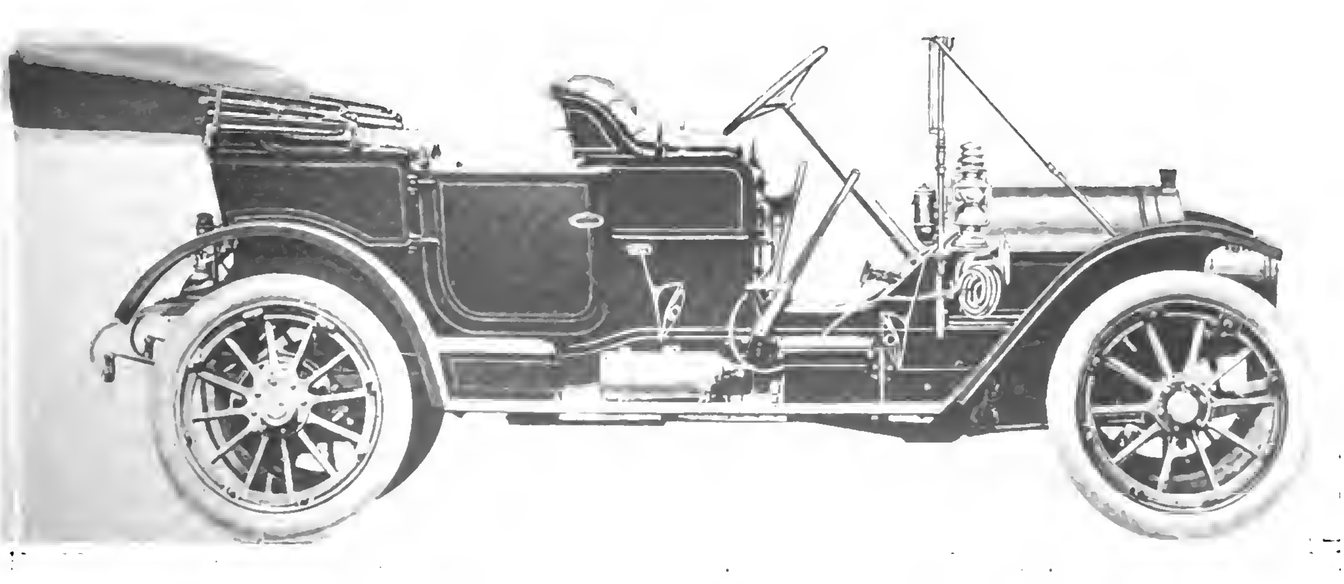

Fig. 6—Stearns model 30-60 presented complete for touring, offering evidences of ability and refinement

THE PROGRESSIVE TESTING OF MOTORS AND CARS

INCREASING output has its viscissitudes as well as its advantages. While it is admitted that the overhead charges reduce in dollars per automobiles built almost inversely proportional to the number of cars made, the fact remains that this can only be a true approximation if the facilities afforded are such as to avoid conjecture during the process. When it became apparent to the builders of automobiles that quantity production was an absolute necessity, not only in order to be able to supply the demand, but with a view to building well at a reasonable cost, it was directly realized that the testing question would become a source of much annoyance, if not a serious stumbling block, unless a means could be found which would permit makers to test as they go along.

It is useless to try to get out of testing every motor made; the necessity of testing really increases with the output. The chances of making mistakes are relatively slight when but a few men are employed, but they grow out of all proportion to the increasing product. When a man starts out to build one motor for use in say one automobile he no sooner completes the mechanical task than he busies himself in a prolonged and exacting test to ascertain the extent of his success. When the same man undertakes to build 1,000 such motors, he becomes enmeshed in a mass of intricate details, and if his caliber is inconsistent with the proportion of the undertaking, it is easy enough for him to conclude that further testing is inconsequential, and he abandons himself and his product to the uncertainties of fate.

The builders of automobiles of the class who succeed fully understand that if they fail to master the great task it will master them. It is a great task to test a large number of motors every day, and the only way it can be accomplished is to contrive a means at whatever cost of time, ingenuity and money. In the plant of the Regal Motor Car Company, Detroit, Mich., the problem has been coped with successfully and fortunately, and as it is the purpose here to show, the scheme employed has the merit of being simple as well as reliable.

When the motors are assembled, after the parts are completed, inspected and accepted, they are transferred to the initial test department, a section of which is shown in Fig. 1, where they are given a run-in test. In this undertaking the motors are operated under conditions of profuse lubrication, and they are given a critical inspection in divers ways, the idea being to note that they are complete and likely to survive in a more extended test under load conditions. As soon as the motors comply with the terms of the run-in test, all of which, for a given motor, transpire within an hour or two, the motors are dissembled, all the parts are given further inspection, thoroughly cleaned and the reassembling (which should be final) is undertaken.

After the final assembling all but a certain percentage of the motors go to the regular block test, a section of which is shown in Fig. 2. In this test they are run for a sufficiently long time under approximately normal conditions to ascertain as to their competence, in view of the service to which they are to be put, and the testers, who are skilled in this undertaking, go through a fixed formula and make records on a systematic basis, which records are properly numbered, identify the motors for all time, and reach the desk of General Manager Haines before 10 o'clock on the morning of the following day.

Throughout the plant everything moves in hundred lots, the idea being to complete 100 automobiles in each lot within the shortest possible time, consistent with the aim which is to build automobiles to live up to the Regal reputation. The management recognizes the fact that it is possible for the routine operators to drop into a groove and thereafter fail to appreciate the necessities of the occasion. To guard against troubles of this sort, a certain proportion of all the motors made are picked at random by the head of a separate testing department and are taken away to the electro-dynamometer room where they are put through just such a test as will bring out trouble, if there is any, and show the competence of the motors in any event. Fig. 3 presents the type of electro-dynamometer used, in which M1 is the motor to be tested, the arms of which are bolted to angle irons A1, which in turn rest upon cast iron standards S1 and S2, and they are supported by I-section beams B1 and B2. The beams extend across to the cradle C1 and C2 of the electro-dynamometer. The armature of the electro-dynamometer A1 rotates on its spindle, which is centered in the outboard bearings which extend up from the cradle members C1 and C2. The field F1 of the electro-dynamometer has inverted radially disposed poles upon which windings W1 (multipolar type) to the required number of ampere turns arranged for separate exciting are placed. The arm A2 extends out for a predetermined distance, and supports the weight W2, by means of which loading is accomplished.

The armature windings of the electro-dynamometer connect to brushes through a commutator in the ordinary way, and an external circuit runs to the switchboard S3, where the switches, instruments and field rheostat are placed. Resistance is introduced into the armature circuits according to the demands, by means of a water-rheostat W3, which is connected to a switch on the switchboard by the use of insulated copper wire of a suitable section, in view of the load to be carried. Varying the resistance of the field alters the excitation, and speed regulation is thereby accomplished. Varying the resistance W3 in the armature circuit changes the output of the same in the proportion of I square R equals W, which divided by 746 equals horsepower when I equals current in amperes, R equals resistance in ohms and W equals power in watts.

The field F1 of the dynamometer tends to rotate and it is only prevented from doing so by the weight W1. In ascertaining the power of the motor M1, it is brought up to the desired speed.

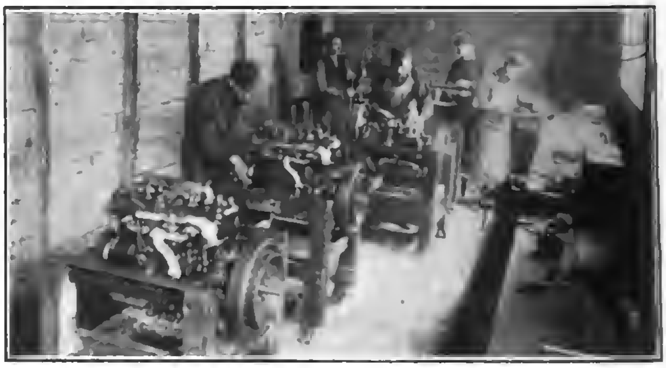

Fig. 1.—Preliminary run-in test under conditions of profuse lubrication, made for the purpose of ascertaining general competence of the motors.

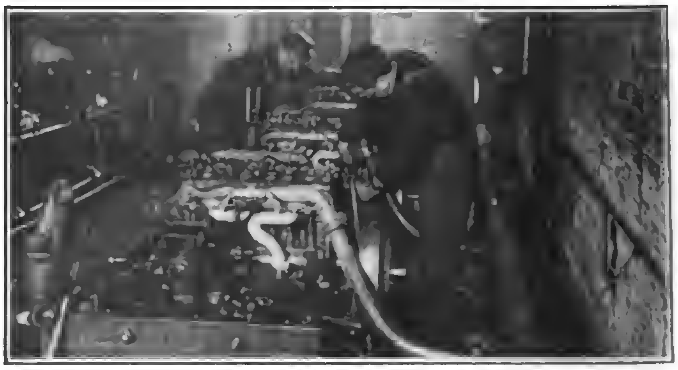

Fig. 2.—Regular block test, made under the most exacting conditions, during which time the motors are tuned up and put into serviceable condition.

measuring the same by tachometer, and the weight W1 is increased or decreased as the occasion requires, until the arm A2 assumes a horizontal position, when the power of the motor M1 is at its maximum for the given speed, provided the weight W1 is all that the arm will bear and remain in a horizontal position.

There are two ways of determining the power of the motor M1. If the electro-dynamometer is calibrated, and its internal losses are thereby ascertained, the power will be proportional to the electrical output multiplied by the percentage of efficiency in which W equals E multiplied by I, when W equals the output of the armature of the electro-dynamometer in watts, E equals the potential difference across the terminals thereof in volts, and I equals the current in amperes from the armature, and this may be reduced to horsepower by dividing by 746.

The excellence of the electro-dynamometer is thoroughly well established. Its accuracy may be measured to within a fraction of 1 per cent., and its flexibility is such that the testers, who have great skill in this connection, are enabled to investigate a goodly number of motors within a relatively short time.

After the motors are completed and tested, and assuming that the check test on the electro-dynamometer accords with the

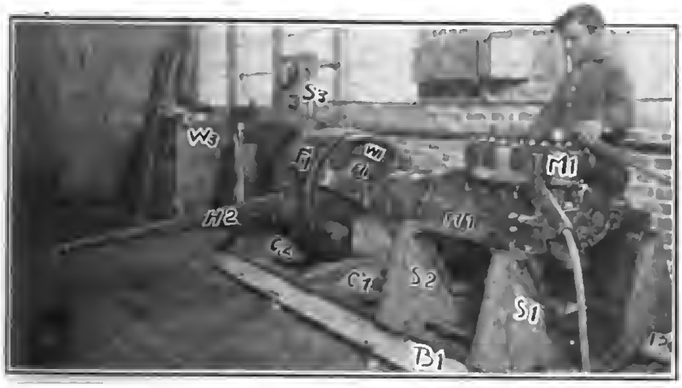

Fig. 3.—Electro-dynamometer, which is used in the check test of a certain percentage of the motors, they being taken at random

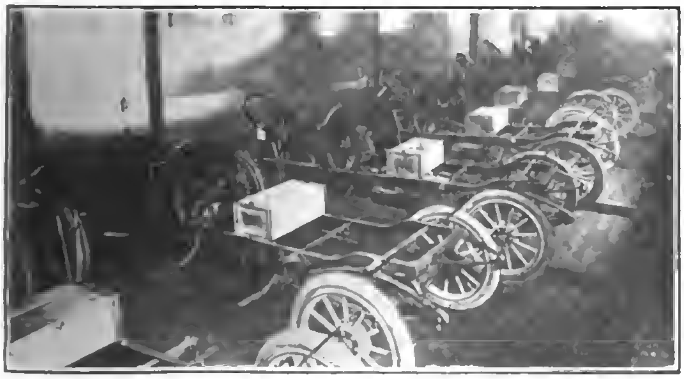

Fig. 4—Chassis test which is made on every chassis completed before the cars are put upon the track for their final test

desires of the general manager, they are assembled into the chassis, and Fig. 4 depicts the next proceeding. The chassis are run into an iron house, after which they are jacked up at the rear. the motors are cranked and the cars are thus given a running test. All cars so tested that prove to be noiseless and satisfactory in general are taken out of the chassis test department, put onto a track on the company's property, and run by a chauffeur whose duty it is to carefully note the extent of satisfactory performance, and report in writing just what he finds. the character of which, in his judgment, is inharmonious. The whole idea, from start to finish, is to test out the parts and the products progressively and in step; to be able to determine deviations from a fixed standard before it is discommodingly late, and to correct evils so quickly and efficaciously that each hundred lot of cars will come through on time.

SPECIFIC INSTRUCTIONS PRODUCE RESULTS

BY O. G. A.

OF the devious ways of country garage men with the innocent motorist, the stories seem to be without end. A New Jersey owner was telling his experience the other day.

"When I got my little 4-cylinder runabout," he said, "I was about as green as they make 'em. I had no particular trouble with the car, except that my batteries were everlastingly giving out. I didn't know then what the matter was; I simply ran into Smith's garage and asked him to fix the engine up so it would run. He'd fix it up, all right, and it would run beautifully. I would take the car out, and in a day or two it would begin to miss. I learned to expect trouble as soon as the missing began, and to head for home; but many a time I was hung up on the road, miles from anywhere. The engine would run a little, a few hundred yards, and then quit. When I was tired cranking I would rest. I didn't know it, of course, but I was giving the battery a chance to rest, too. Presently I would turn the crank and the engine would start, and I would run for a mile or so and repeat the performance.

"When I got the car to Smith's I would ask him what ailed it, and he would say that he would have to look it over. I would leave it there, and in a couple of days he would report that the valves needed grinding or some other fool thing, and I would pay him $10 or so for his trouble. Of course all he did was to put in new batteries, half-dead ones at that.

"One day I left Smith and started for a town six miles away, where the nearest agency of my car was located. I was three hours getting there! The same old performance took place, and I am afraid to say how many times I objurgated that car. When I reached the agency all the mechanics were out, leaving only a boy in charge of the place. My battery was so far spent that he had to help me push the car into the garage. As the men were out I thought I should have to wait, but the boy ventured respectfully to assert that he could fix me up. I asked him if he knew what the matter was, and he said 'No, but that he could soon find out.' In the end I let him go ahead. I didn't watch him, but in ten minutes he had that engine running as well as I had ever heard it. I asked him the charge, and he said, 'Two dollars.' I asked what for, and he said, 'One dollar and fifty cents for new batteries, and fifty cents for my time.' I paid it, thanked him, and then asked how soon I would probably be in trouble again. He climbed into the seat and felt of the coil tremblers. Then he said, 'These batteries will run you about seventy miles; in a minute I will fix them so they will run you three hundred.' I watched him then, and all he did was to slacken the tension of the contact screws on the tremblers! That rascal, Smith, not content with selling me dead batteries at $10 or $12 per set, had screwed down the contacts so they would eat up what little current was left as fast as possible. I went my way in the glow of a great light.

"A few days later I stopped at Smith's for gasoline. He asked casually, 'How's your car running?' 'Splendid,' I said. 'I thought so,' said Smith, cheerfully. 'I knew the last time I fixed you up that it would run all right.' 'Smith,' I said, 'do you know how long it took me to get to town after I left you that day? Well, it took me three hours. It wasn't you that fixed me up; it was a fellow at the agency in town.'

"Smith looked at me in a queer sort of way, and asked, 'What did he do?' 'Nothing in the world,' I told him, 'except to put in *good* batteries and slacken the tension on the tremblers.' At that Smith turned on his heel suddenly and walked away. But as he did so he flung back the remark over his shoulder, 'I guess I shan't get any more easy money out of you!'

"Well, he didn't, for from that day to this I have never left my car in Smith's garage or any other without giving explicit instructions as to what I wanted done, standing by to see it done, and then taking the car out immediately when it was ready to run. In all, my experience with Smith cost me $58, but I know now that it was money well spent for education."

Pertinent Features of Abbott-Detroit Car

THIS year is the one of conspicuous company efforts in the automobile line, and visiting the plants of the respective companies discloses a wide variation in the methods employed by them respectively, each one being a study in itself. In the Abbott-Detroit plant, of the Abbott Manufacturing Company, the car which is being turned out sells for $1,500, and with a touring body, seats five persons. The method involved in the manufacture, if such it might be called, is entitled to even greater mention than the product itself, because of its excellence, but as might be expected, excellence of the method employed is reflected favorably in the product.

In this establishment a unit system of production obtains throughout; the materials come in through the receiving door, are sorted into their respective generic types, and pass on to the preliminary testing room wherein they are carefully inspected and counted. If some of the materials fall below the exacting standard set by the company for its inspectors, they are moved to the right into a room wherein doubtful products await the action of the production manager, whose power of final decision enables him to promptly approve of the inspectors' marks, and return the materials from whence they came. The good materials pass on to the general storeroom, and are there sorted out in such a way that they may go into the shop in assembly boxes, each box holding the requisite number of pieces or parts, and such materials in the rough as may be required to satisfy an assembly order.

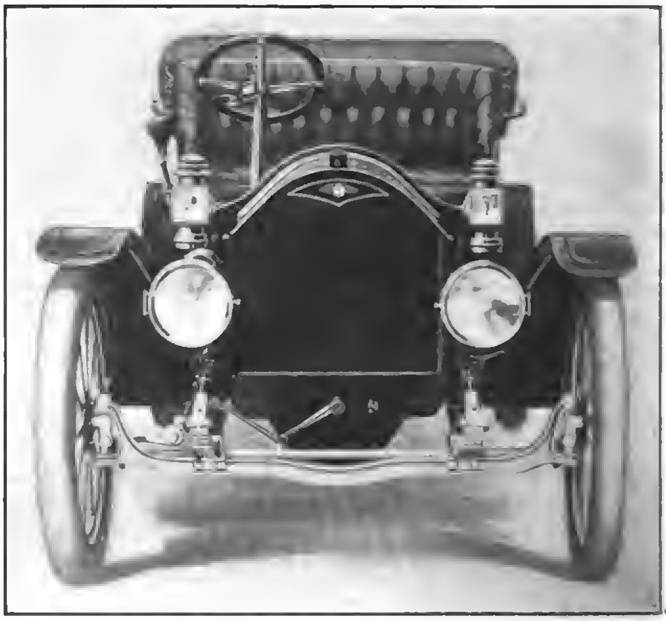

Fig. 1—Looking at the front of the car showing I-section drop axle, protected cross-rod and drag link

In the shop, at every point, the same idea obtains throughout the work. "Schools" of materials advance from one stage to another, until in the course of events the units which compose the automobiles are assembled, inspected, and then pass on to the testing department, wherein competence is proven, or defects uncovered. Should an assembly unit fall below the established standard during test, it is sent back to the department responsible for the inferior work, is dissembled, and the parts are then re-inspected, during which time the trouble is definitely located, responsibility is centered on the individual who may have disregarded the requirements, the parts which do not conform to the needs are cast out, and after re-assembling the unit is again returned to the testing room, with the expectation that it will come up to the chief tester's requirement.

This method of grouping materials has a wide influence on the product of the plant, and the cost thereof. In the average shop, much time is wasted by the workmen, who, when they are instructed to proceed with a shop order, must first lock up the material list, determine the character and quantity of materials required, and then stand in line in front of the store room distributing window awaiting their turn, always with the opportunity to kill a considerable amount of time, which they do pleasantly enough, since they have company, and the environment is ripe for unprofitable discussion. By means of tote boxes, in which the materials for a given job are placed and checked off by the store-keeper long before they are required by the respective workman, all delays as above indicated are done away with.

GENERAL CHARACTERISTICS OF THE ABBOTT-DETROIT CAR

The motor is of the 4-cylinder water-cooled type, with a bore of 4 inches and a stroke of 4 1-2 inches. The cylinders are

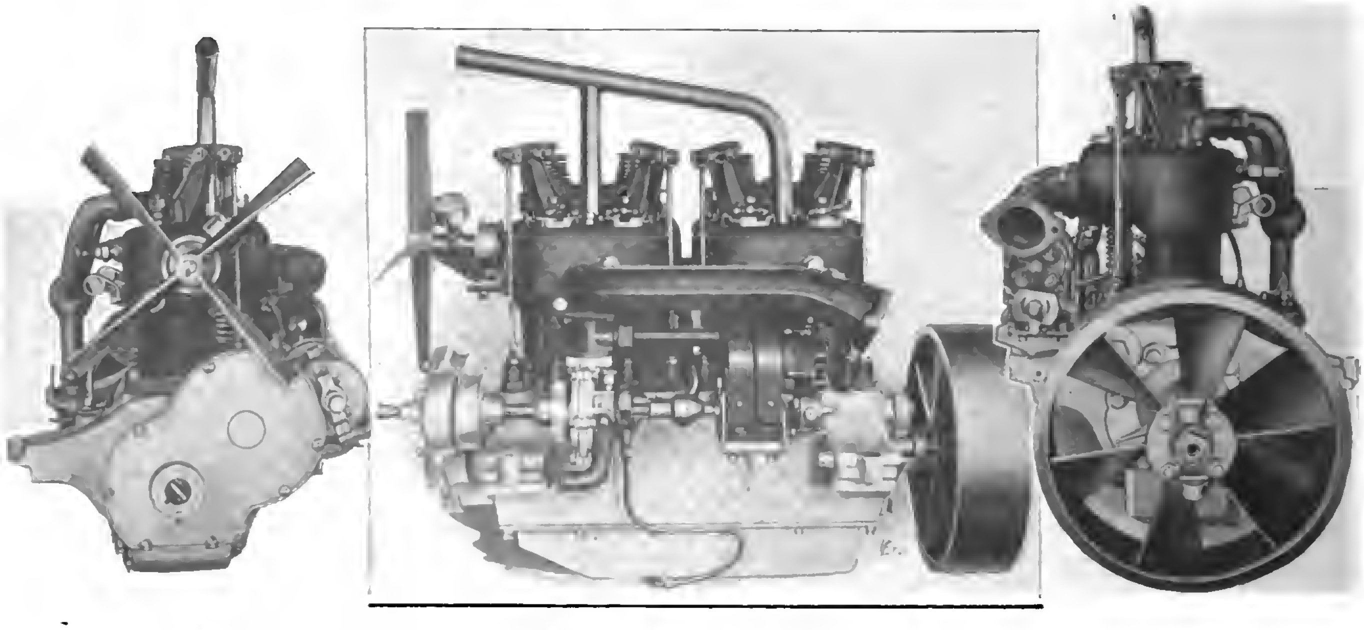

Fig. 2—Three views of the motor showing pump and magneto on one side, and a fan in the flywheel

cast in pairs of gray iron, and the motor is normally rated at 26.5-horsepower. The valves are located with the inlet on top, and the exhaust on the side, and the timing is that which obtains in satisfaction of the 4-cycle principle. The general appearance of the power plant is shown in Fig. 2, with three views, the one on the left being the front end of the motor, indicating how the half-time gears are completely encased; the middle view presents the left side of the motor, and indicates the manner in which the water pump and magneto are driven by an extension shaft which passes out from the half-time case, back through the water pump, thence to an Oldham joint, beyond which the magneto is placed on a shelf which projects out from the top half of the crankcase. At the right, the rear of the motor is shown; the flywheel is of large diameter, and the spokes form fan blades, which exhaust the air from the hood, whereas air is pulled through the radiator by a fan in front. The water cooling, in view of the use of a commodious centrifugal pump, a fan in the flywheel and one in front, is most thoroughly accomplished, and the performance of the motor reflects the completeness of this system.

The valve system, and the method of its application, will be best appreciated by referring to Fig. 3, which is a view of the two pairs of cylinders looking down from above, with two of the valve cages removed from the cylinders at the left, which cages show, as the figure at the right, with a screwdriver so placed that it pries one of the valves off of its seat against the pressure of the valve spring. Obviously, it is a simple expedient to remove a pair of valves with their cages complete from the cylinders, for the purpose of grinding, or in the process of inspection, and the design is so carefully worked out, that the inequalities, due to heat changes, have no ill effect on the service rendered, because the cages fetch up against flat seats, with a clearance in the radial plane, and the joints are ground. The valve springs are of suitable proportions to afford the desired pressure, but the design thereof is such that the springs are alive, and the angular rotation of the camshaft is reduced to the minimum, during the period of closing of a valve under the action of the spring. Matters such as this add materially to the power and smooth-running qualities of the motor, and make it possible to adjust the timing for the best result.

Lubrication is by splash with a pump which is located outside, hence open to inspection at will, and it affords the additional advantage of being readily removed for the purpose of repair. The pump takes its power from the camshaft, and the oil is circulated by pressure to whatever extent positiveness is necessary and by gravity for the rest. Fig. 4 shows a section of the crankcase in the region of the half-time gears, and a close examination thereof will indicate quite readily how profusely lubrication is induced, but additional sections would have to be used to more clearly indicate the means at hand for draining the used oil away from the bearings, thus permitting a fresh supply to supplant it continuously.

While attention is riveted on Fig. 4, it will be timely to call attention to the camshaft which has one very large end bearing at the gear end, a relatively large bearing at the opposite end, and two intermediate bearings proportioned for their responsibilities. The cams are cut integral, and attention is called to the design of the lift, which is in two parts, one part of which, with its mushroom, engages the cam, and the other part engages the rocker-rod stem. An intervening spring presses between the two engaging members, and the result is that noise, due to lost motion is aborted. An adjustment is provided, whereby it is possible to re-establish the timing of the valves quickly and readily should the occasion require. Ignition is by jump spark, utilizing what is known as the dual system, involving a magneto in the main, and a coil and battery for auxiliary work, with a hand control. Splitdorf magneto is the regular equipment. Carburetion is accomplished with a Mayer carbureter, and the fuel is fed from a tank of suitable proportions, by gravity.

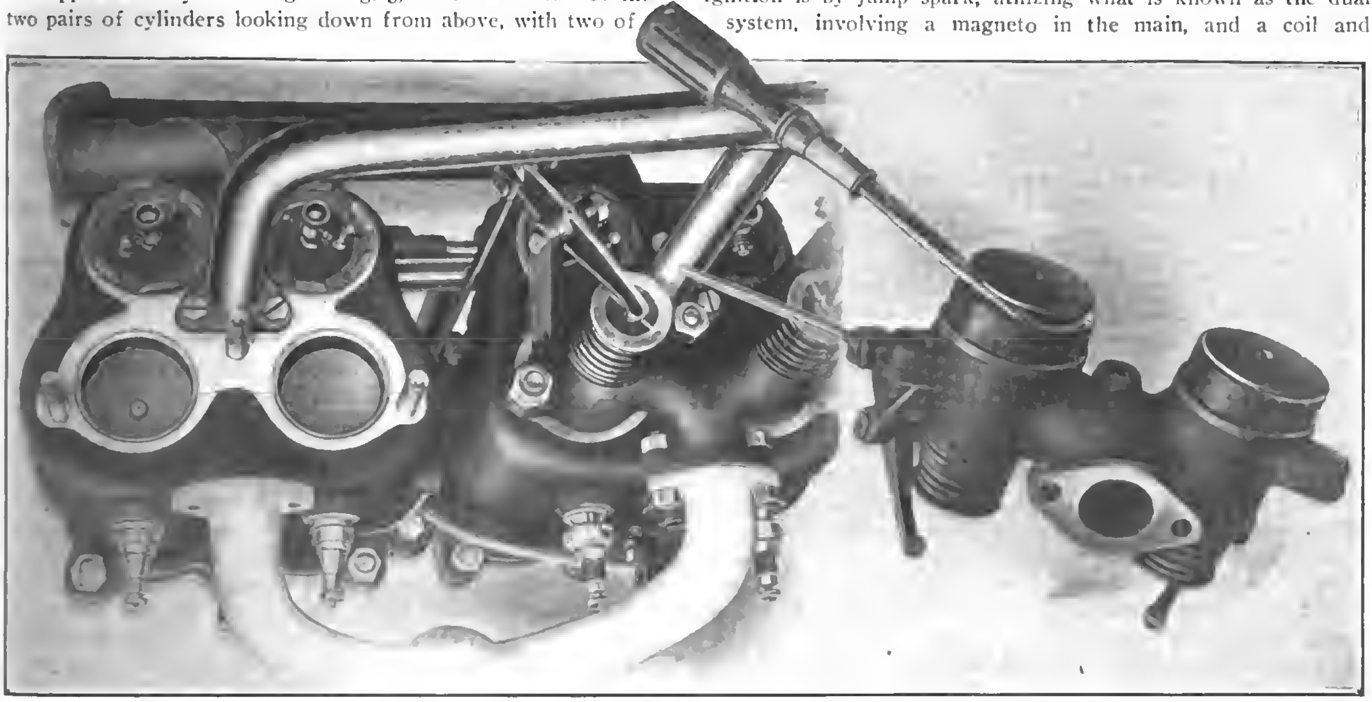

Fig. 3—Looking down on the motor presenting details of valves in the head with one pair removed and presented at the right

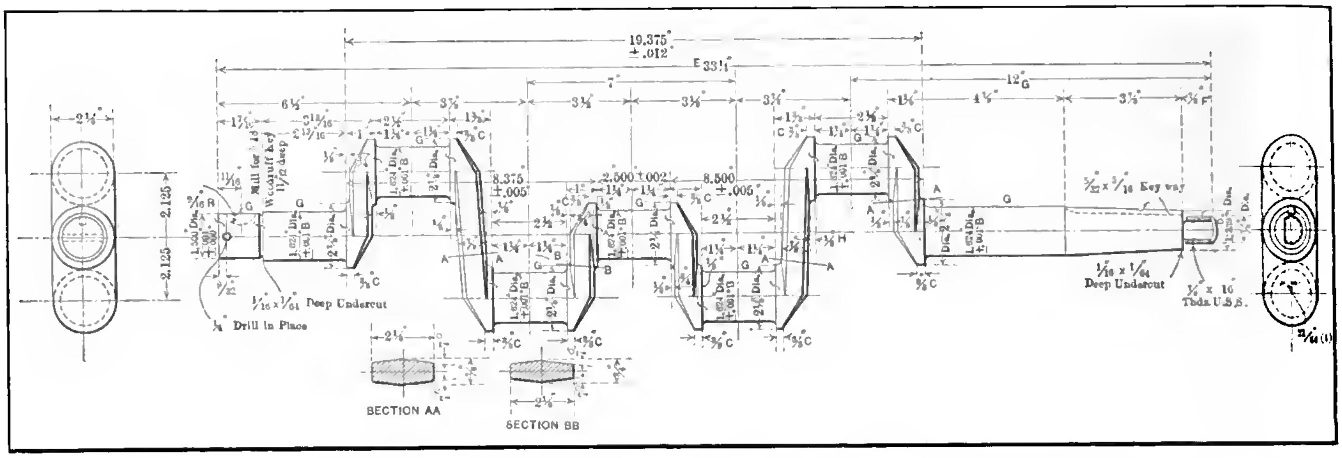
In further recognition of the mechanical makeup of the car, attention may be called to a multiple disc clutch with steel on steel, and a sliding-gear system of the selective type, located amidships. This gear has three forward speeds and reverse. It is related to a shaft drive through suitably disposed universal joints, terminating in a floating type of rear axle, with the reactions satisfied by means of a well-designed torsion rod.

The bearings in this model comprise three, which are plain in the crankshaft of the motor; the camshaft bearings are plain also. F & S ball bearings are used in the road wheels and rear axle system, excepting for the front wheels, which have Timken roller bearings. The plain bearings used in the car are lined with Parsons white metal.

The wheelbase of this model is 110 inches, with a 56-inch tread, and the wheels are fitted with 34 by 3 1-2-inch tires front and rear. The spring suspension of the chassis is semi-elliptic front and three-quarter elliptic rear. The front axle is of the



Reproduction of Working Drawing of Crankshaft, Showing Liberal Sizes, Large Fillets, and Close Work Required

I-section, drop forged of suitable material, and the yoke for the knuckle is of excellent strength, the mechanical arrangement is noteworthy, and the knuckle pivots on a large ball, which renders the steering motion nearly frictionless. The rear axle construction, as shown in Fig. 5 presents some features with novelty in their makeup. A single F & S ball bearing in the plane of the load is responsible for the good performance, the hub fetches up on a taper, is pressed home by a hub-nut of good proportions, and dirt is excluded by a cap, which screws on and fetches up to a shoulder, hence stays on without the use of further locking devices. Pressed steel parts are used in the hub construction, and closures prevent the grease, which is placed to lubricate the bearing, from pressing out or becoming contaminated. The brake drum centers on the pressed steel hub member, and the drum is of excellent diameter, made of pressed steel with a closure to prevent mud from interfering with the performance of the internal expanding brakes.

Referring to the differential system and bevel drive, the differential gears are of the bevel type, the jackshaft members have square ends and register with square holes in the differential gears. The differential housing is of substantial construction, and the holding bolts, which sustain the two members in their proper relation, are also used in bolting the bevel gear into place. The driving pinion of the bevel drive fetches up on a taper of a stub-end shaft, and a large cup-and-cone ball bearing is in concentric relation with an extension of the hub of the bevel pinion, thus assuring that the pinion will hold to its pitch line relation, and the thrust is also taken by the same commodious cup-and-cone ball bearing. In order that this stub-end shaft, which carries the driving pinion, will sustain the relation of the pinion to the gear, a second cup-and-cone ball bearing is utilized at a considerable distance away, so that the resolved component of the relations of the pinion and gear will not induce an undue pressure, tending to distort the stub shaft out of its true location. The stub shaft connects with the propeller shaft through a universal joint. The whole system is carried in a spherical member which is suitably ribbed and nicely designed, and made by the steel-casting process. The steel tubing which composes the rear-axle shell is of large diameter and is selected for strength, care being taken to sleeve the tubing where it joins the shell, with a sufficiently long bearing to guarantee the future good performance of the axle as a whole.

Attention is also called to the working drawing of this rear axle, in particular, the outer end of it, which shows the single ball bearing previously mentioned, as well as the balance of the construction. The brake drums are of pressed steel, in a single piece, and are bolted up to the two other parts of the hub in such a manner as to form practically an integral part, with a corresponding gain in strength. Within this drum works the brake, of the expanding band variety, the construction of the brake supports being such as to completely close all openings left for assembling purposes, thus rendering the whole dirt and dust proof. This latter brake support is so formed as to bear on the axle tube for a very considerable length, making it very strong and a rigid support, while stiffening the ends of the load-carrying axle as well. In the section through the engine showing the valves, it will be noted that the latter are of the conical-seated variety. Similarly, attention is called to the fact that the piston pins are fixed in the piston with a two-diameter pin, cotter-held.

AERONAUTIC PROGRESS ALONG CONSTRUCTIVE LINES

By MARIUS C. KRARUP

STEERING devices, rudders and keels are among the elements of construction which engage most attention among aviators at present, but what is most important with regard to their mechanical action, in combination with the most successful aeroplanes of to-day, is likely to be found of little consequence, as soon as improved planes, propellers and motors make their appearance. Only the fundamental principles of these elements will then be of interest. But for a number of years to come the tilt-rudder usually in front of the biplane and the vertical rudder usually to the rear, as well as the corresponding members in monoplanes, must be reckoned with, somewhat as hot tube ignition and "hit-and-miss" motor speed had to be studied for years in the automobile industry, until improved carbureters and progress along the whole line made throttle control and the magneto practicable. Learned discussions on the relative merits of governing "on the intake" or "on the exhaust" are now remembered with a smile. And at all times some of the constructors knew that those expedients could only be temporary makeshifts; yet, they had to be employed.

In the art of aviation, soon to be an industry, much of the progress which is theoretically in sight must probably await the advent of suitable construction materials in suitable shapes, combining strength, lightness and elasticity in a degree which can never be developed in a wood-and-canvas structure. The makers of fine alloy steels have here an open field for experimental work, relating to the economical production of thin structural shapes, most of them elongated and tapered, others in the form of joints and clamps, and all of them uniformly heat-treated at the producing plant and preferably made from a single, standardized "aviator's alloy," highly dependable, and whose strength in any given size and shape may be calculated to a nicety. While the pressed-steel frame, and the processes which made it possible, proved highly adventitious to the automobile industry, the production of aeronautic steel lumber, adaptable to experimental construction, would seem to be outright indispensable for substantial progress in aviation, as the constructor must be released from bondage to unreliable woods, especially weak and bulky in the joints, before he can get elbow room and begin to materialize his ideas. The latter may be faulty or correct, but as a rule they will be "between and betwixt," and will require demonstration before their worth can be decided. But while the evolution of special aeronautic construction materials is foreshadowed and necessary, it will require time, and during the years which must pass before such materials are likely to be available, the design of the thousands of aeroplanes to be built must probably include tilt rudders, steering rudders and such slight warping of planes for steering purposes as wood construction admits.

Mere keels, unadjustable and inapplicable to any kinetic purpose, are already passing into the realm of superstitions or preconceived notions, as it has become perfectly plain that they are just as much of a hindrance to the regaining of equilibrium as a help in preserving it. As their alleged utility has never been founded on theory, it need not be theoretically gainsaid. Their use has mainly served as a reminder of something faulty in other parts of the construction. The seesawing of the main planes, which they were intended to prevent, was a symptom partly of overconcentration of weight along the axis of the machine and partly of shiftiness in the support afforded by the planes, and the logical remedy has been found, by those constructors who use no keel, in better distribution of weights, the use of more strongly curved planes, whose support is less variable from accidental influences than that derived from planes of small curvature, and in the manipulation of vertical rudders. But weight distribution has not yet been found feasible for monoplanes, and here the remedy taking the place of stabilizing keels is the adoption of the dihedral angle, so-called, in conjunction with a low center of gravity, as in Latham's well-known machine.

The principle at stake is that of mobility versus inertia, for preserving equilibrium. In favorable weather the inertia elements, whether keels, vertical or horizontal, or tails, produce the steadier flight, perhaps, but in irregular weather the mobility principle wins out. The main question in this respect is clear: Should air resistances, which are not subject to graduated control, be employed as means for controlling equilibrium, when air currents are the disturbing element to be guarded against? The analogy drawn from the steadying effect of the keel of a ship loses all force, when it is considered that the ship's keel is not itself exposed to the action of either waves or winds, which are the disturbing factors in navigation. In aviation, keels are not to be.

The tails of monoplanes combine two elements of inertia, one derived from the trailing weight, which at present serves the double purpose of keeping the machine head on, so long as the motor and propeller work, and of suppressing irregularities in the tilt and support of the planes, and the other consisting in the air-resistances which oppose any rapid displacement of their extended surfaces, except in the line of motion of the machine. These two elements of inertia in conjunction destroy the advantages which the monoplane should intrinsically possess in the way of superior speed, due to the smaller air resistance against propulsion of its single plane, and explain why it has not been able to maintain this supposed speed-superiority in contests.

In the biplanes, some lack of uniformity in the support afforded by the planes is acknowledged in the considerable distance from the front edge of the main planes, at which it has been necessary to place the tilt-rudder. As the tilt-rudder is small in comparison with the main planes, it must be made to act with great leverage against any tendency which the main planes may develop toward pitching forward or backward. This tendency, with properly curved and narrow planes, should not be very pronounced. Even a somewhat irregular wind will usually drive the whole aeroplane machine before it rather than raising or lowering any part of it, similarly as the housefly is saved from a clumsy pursuing hand by the air current preceding the attack. But safety against the exceptions to this rule is vital, and the tilt-rudder is intended to supply it. And, while every biplane is supposed to be so balanced by its designer that its weight is distributed evenly on both sides of its axis, and also to the front and rear of a line which may be drawn parallel with the front edge of the planes and, roughly speaking, about one foot behind this edge, the corresponding line indicating the transverse axis of aerial support does not stay in one place, but shifts forward with an increase of speed and backward with an increase of load, and the tilt-rudder is relied upon to take care of these changes in the fore-and-aft balance of the machine, through proper manipulation. At high speed, the tilt-rudder is desired to cut the air quite edgewise, no forward lifting action being required of it. But, if the machine is intended to be used mainly at some lower speed, the size and distance of the tilt-rudder from the main planes should be so adjusted that it will cut the air edgewise at that particular speed, because this arrangement will give a maximum range of effective rudder action for control and safety, namely, 20 degrees of deviation on both sides of the direction of motion. It has been experimentally demonstrated that rudders of present construction reach their maximum effect at that deviation, so that nothing is gained by turning them farther. Fortunately, the nice balancing of the whole machine involved in procuring these results may be obtained experimentally not only by adjustments of the area or leverage of the tilt-rudder, but also by moving the

Looking for Civilization in Texas

Fighting Texas Roads near Sierra Blanca

Through Swamp and Desert to Pacific

AFTER fighting four days in the teeth of a driving sandstorm, Walter H. Hanson and his transcontinental touring party recently swung into the frontier town of Mecca, on the edge of the great desert, tired from the battle with the elements but happy in the unusual accomplishment. The dust and sand had penetrated to the depths of their beams, but the car, a seven-passenger Stearns, weathered the gale in good style. From Mecca to Los Angeles the tour was pleasanter, although the roads were terribly rough. Mr. Hanson, who is a wealthy broker of Saratoga Springs, N. Y., his wife, son and chauffeur appeared to have enjoyed even the more strenuous of the incidents of the trip from ocean to ocean.

They were mired in Louisiana, mobbed in one of the swamp parishes, traversed some of the most forbidding trails of the country, but arrived at their destination in good health and spirits.

"We made Phoenix all right," declared Mr. Hanson upon his arrival at San Francisco, "and there we picked up George Dake, who acted as our guide through to Los Angeles. Of course even Mrs. Hanson had become hardened to the bad roads of the South and the jolting didn't bother us much. We reached the Colorado River all right and were ferried across by the Indians and pulled out of Ehrenburg Thursday morning expecting that with ordinary luck we would reach Mecca that night.

"The sandstorm on the desert was something indescribable. While it was an extremely trying experience insofar as our eyes were concerned, I enjoyed it to a certain extent. The wind blew the sand so that one could not see 20 feet ahead. The sand was deep and fine as powder, making it a hard matter to hold straight the big car with its 6,000 pounds of weight. Sometimes we could see the tracks of a wagon which had gone ahead, and sometimes the road looked just like any other part of the desert. We didn't get lost, but I can easily imagine how an automobile could lose its bearings going over the stretch of country between Mecca and Ehrenburg.

"But when you strike the civilized portion of California, then you begin to realize what a paradise it is. Outside of a few roads in New Jersey, I don't know of a State that can boast of such good, ordinary highways as southern California. Talk about your bad roads, why California highways are as asphalt pavements beside them!

"Down in Louisiana we were held up one night by a band of ruffians who declared that we could not pass. I turned around; went back to the nearest town, got the deputy sheriff out of bed and then, he standing on one running board and I on the other with gun in hand, forced our way through this terrorist mob."

The run from Mecca to Los Angeles, a distance of 154 miles over some of the worst roads in the southern part of the State, was made yesterday with the son at the wheel. The transcontinental party was met near Pomona by a party of newspaper men, who piloted them into the city. On the return into the city, the local car was left behind by young Walter Hanson, who came flying over an unknown road faster than most road racers would want to take it.

At present the Hansons are touring in California and are not sure when they will return to the East.

Figures and Deductions From 1909 Exports and Imports

IN the yearly summary of the foreign commerce of the United States, the figures interesting to automobilists would seem to have been carefully buried under a subdivision of comparatively small moment, that is to say, in classifying automobiles and their parts under the heading of "Carriages, Other Vehicles and Parts of," the Bureau of Statistics of the Department of Commerce and Labor seems to have given the lead to the insignificant part. In short when the division is called "Carriages," when carriages amount to but 1 per cent. of the total, while automobiles and parts consist of the other 99 per cent., it really seems like a case of the tail wagging the dog. It is time that the automobile manufacturers rose in their might and had this changed.

Getting right down to the figures, some very interesting facts are there brought out. Thus, in the summary of commerce with non-contiguous countries, the fact appears that our trade with the Philippines and Porto Rico has dropped off, while with Hawaii, on the other hand, such a big increase is noted as to nullify the other two losses.

SHIPMENTS OF CARS, CARRIAGES, AND PARTS TO PORTO RICO, ETC.

Year.	Porto Rico.	Philippines.	Hawaii.
1907	$615,720	$166,359	$339,711
1908	563,829	261,628	452,040
1909	548,509	129,995	707,540
Change Over 1908	— $15,320	— $131,633	+ $255,500

From the above, it would appear as if the automobile manufacturers had not given enough attention to the Philippines or Porto Rico, to their own loss.

As a concrete expression of the business done by American manufacturers, the summaries of total exports and imports are of much interest, although the previously mentioned combination with carriages and carriage parts somewhat beclouds the exact facts. At any rate the constant increase and its changing each year will be given thus:

VARIATION IN TOTAL EXPORTS OF CARRIAGES, ETC.

Year.	Value.	Net Change for Year	Change in Per cent.
1903	$10,499,195		
1904	10,936,618	+ $437,423	+ 4.16
1905	10,610,437	— 326,181	— 2.93
1906	17,788,425	+ 7,177,988	+ 67.6
1907	20,513,407	+ 2,724,982	+ 15.3
1908	22,072,902	+ 1,599,495	+ 7.56
1909	15,392,817	— 6,680,085	— 30.2

Probably the most noticeable and also the most surprising thing in the above table is the radical falling off of the business during 1909, as compared with 1908, which latter is not thought of as a good year, at least not particularly so in the automobile business.

Geographical distribution is valuable when tabulated, for the reason that a country taking a big percentage of present exports should be a good field for a maker just starting in to export, rather than virgin territory. In the Government summaries the grouping is very general, there being but six grand divisions, the exports to which for 1909 were:

DISTRIBUTION OF EXPORTS BY GRAND DIVISIONS

Division	Amount	Percentage of Whole
North America	$6,485,742	42.10
Europe	4,229,802	27.50
South America	3,084,187	20.10
Oceania	857,126	5.55
Asia	527,579	3.42
Africa	208,381	1.34
Total	$15,392,817	100.01

In this table the surprising thing is not the amount of trade with North America (Canada and Mexico), but that with South American, Oceania and Asia, these latter three, which the ordinary man would say were negligible, amounting, when added, to no less than 30 per cent., or, in round figures, one-third. All things considered, it would appear as if this part of the world offers the greatest future of all, the untold numbers of people in Asia being an immense field as soon as they can be educated to the benefits of the automobile. Taking China alone as an instance, with its population of 410,000,000, Japan with 45,000,000, Persia with 8,000,000, Siam with 6,000,000, to say nothing of the untold millions of India and Russia in Asia, this virgin field should absorb in years to come all of the automobiles that America and other countries produce over and above their own actual needs, even when, as indicated in last week's THE AUTOMOBILE, the whole production amounts up to the astounding figure of several millions of cars.

In order of amount of duty collected from imports, cars, carriages and other vehicles and parts were number 28, with a total of $1,547,123, upon which the average duty was 44.98 per cent. This amount is divided into automobiles and parts, $1,518,340, and carriages but $28,783. Over 1908 the former showed an increase of $225,280 in duty, 17 per cent., and in value $502,103, an increase of 17.5 per cent. The latter, on the other hand, increased the duty but $4,022, amounting to 16.2 per cent., and in value $10,823, equal to 19.5 per cent. From these figures it would seem as if the value of both automobiles and carriages is increasing faster than the amount of duty paid, this making it appear that cars of a much higher class are imported. If this be true, and there is no reason to doubt it, the case is just opposite to that of exported domestic makes, as the value of each machine exported is on the decrease.

Finally, balancing up the imports and exports for the fiscal year, the balance lies with the home manufacturers to a great extent. The exact figures are: Exports, $5,387,021; imports, $2,905,391, leaving the favorable balance of $2,481,630. With the parts, however, the imports lead, the figures being: Imports, $773,743; exports, $605,179, an unfavorable balance of $168,564. The whole gives a net favorable advantage for American makers of $2,313,066.

Other countries imported and exported large numbers of machines of a high value, for it must not be considered that this country has any monopoly; in fact, just the reverse.

France's exportations of cars, valued at $24,569,000 in 1908, were distributed as follows: United Kingdom, $11,784,000; Belgium, $2,229,000; United States, $2,124,000; Germany, $2,018,000; Argentina, $837,000, while Algeria and other French colonies, India, Egypt and European countries received practically all of the remainder.

Italy exported most of her motor cars to European countries, $1,297,000 worth going to the United Kingdom, $985,000 to Switzerland, $556,000 to Germany, while to the United States the exports were valued at $664,000, and those to Argentina $571,000, these five countries representing nearly four-fifths of the entire motor car exports of Italy during 1908, valued at $5,533,000. From the United Kingdom the exports of cars and parts in 1908 were valued at $6,124,000, of which $592,000 worth went to British India, $573,000 to New Zealand, $176,000 to this country and $123,000 to Canada.

The exports from Germany in 1908 were valued at $2,936,000, together with parts valued at $95,000. The greater part, valued at $567,000, went to European Russia, while France took $517,000 worth, Austria-Hungary $474,000 and the United Kingdom $448,000, while to Italy, Switzerland, Roumania, Argentina, Belgium and the United States, in the order named, were shipped the remainder of the export product.

MOTOR INDUSTRY IN ATLANTA

ATLANTA, GA., Apr. 25—There are over 1,500 automobiles in daily use upon the streets of Atlanta and 95 different makes of cars have agencies in the city, while the location of a big factory is being planned for the near future. The city has taken to the motor car with special avidity and has come to be known as the automobile center of the South. It is stated that the motor industry has done more for Atlanta's recent progress than any other single factor.

BEST PRACTICES LEAD TO SILENT ACTION

MAKERS of automobiles, understanding the situation perfectly, undertake to eliminate noise on the count that it stands for far more than the mere disagreeableness of the discords rendered up by ill shaped parts. To depend upon the ability of the workmen, no matter how skilled they may be, is to court disappointment; and even if the machine tools are the best that can be had, the situation is still confined to the realm of speculation, and in the long run it is necessary to provide instruments of precision in order that the workmen will be able to judge of the results they produce.

In the Rambler plant, as the illustrations here given will adequately portray, this matter is taken up on a basis which is intended to check with the design of the automobiles produced, taking into account the shapes of the parts, the materials of which they are made, and the relation they hold to the connecting members.

Limiting the discussion to the methods in vogue in the production of gears, Fig. 1 presents a quick and accurate method of measuring the diameters, in which A is a gear of the bevel type and B is an instrument which belongs to the extensometer group, and is capable of quickly locating an error of a small fraction of 0.001 inch even when the workman is more or less unskilled.

As a further indication of the extent to which this principle may be carried there is illustrated, in Fig. 2, an instrument which utilizes the principle of the micrometer and the extensometer. The gear G is having its pitch diameter determined; the yoke Y of the instrument holds the micrometer M at one terminal, and the extensometer E at the other. The instrument is so designed that the points jam on between the teeth of the gear just on the pitch line, and the pitch diameter may be determined within a small fraction of 0.001 inch.

Fig. 3 presents still another version of the methods of determining the dimensions of gears, and in this example it is the idea to illustrate the manner of noting how well a set of gears match up with each other. The gear G1 is centered on the plug P3, and the pinion G2 is centered on the plug P2. The distance between the plugs P2 and P3 is exactly right, considering the pitch and number of the teeth of the gear and pinion. The pointer P1 will take up a position of O on the scale S, if the work is so well done that the gear and pinion mesh properly on the pitch lines, but any departure from accuracy will show by the position of the pointer P1 on the scale. The plug P2 is attached to a moving part, so that it may be located with respect to the plug P3, but when the gear and pinion are properly made, the pointer should rest on 0 of the scale S.

As a further indication of the methods reference is had to Fig. 4 of an instrument which is employed to determine the accuracy of the bevel gear. It is just this class of gear that will make noise, if it is not well made, and it is a problem to accurately finish a gear of this character. The gear G, rests on the base-plate B, through the supports S, which are so shaped that they engage the teeth of the gear at two points. If the gear is properly made the depth gauge will show a certain distance between its gauge point and the face of the base-plate. By rotating the gear 180 deg. and taking a second measurement, it is determined whether the gear is warped.

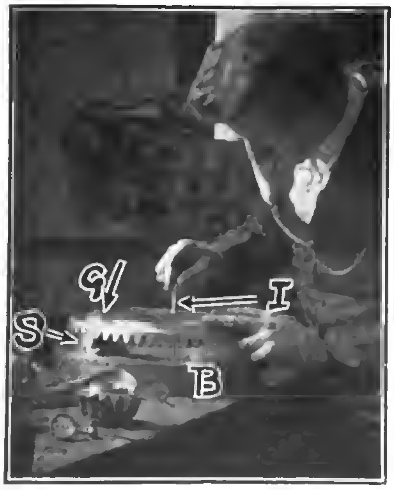

Fig. 4—Instrument employed in the inspection of bevel gears to ascertain if the pitch diameter is right

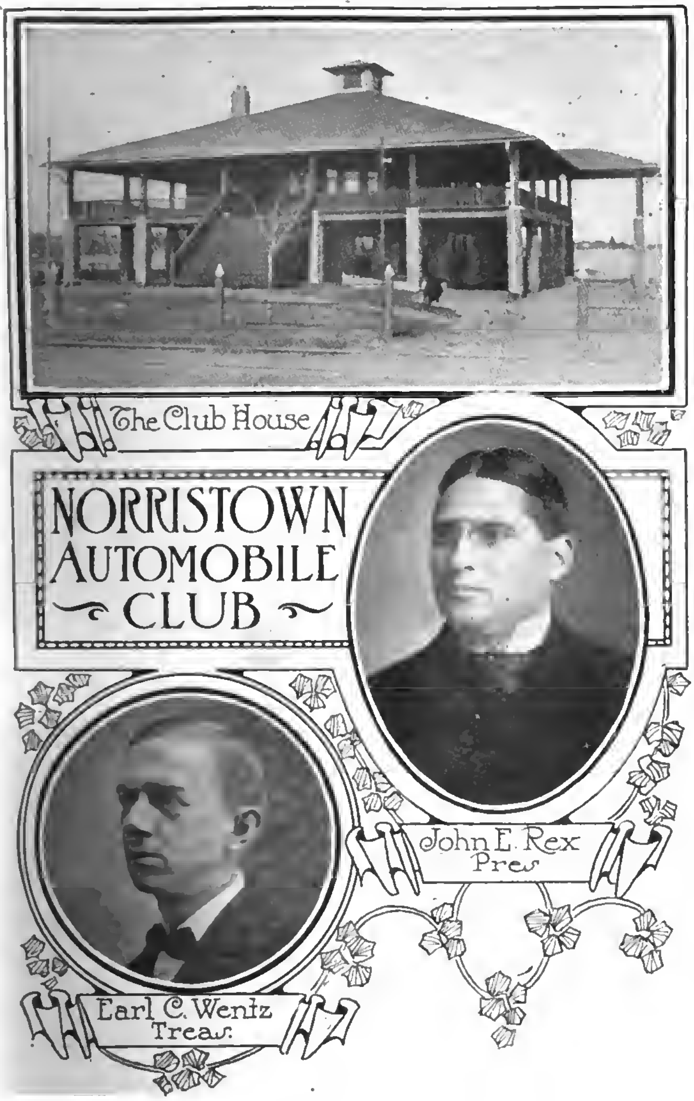
These methods tell of



ONE of the most useful automobile organizations in Pennsylvania, from the viewpoint of actual accomplishment, is the Norristown Automobile Club. It has only been in existence for about three years, but during that period it has done wonders and waxed strong and influential, not only in its own locality, but also throughout the State.

Like all organizations of its kind, it has some very wealthy men on its roll of membership, but, unlike most automobile clubs, the vast bulk of its members are simply active professional and business men whose wealth is still largely potential. As a result and without any slight upon men of money, the club fairly teems with vitality. It does things, and it does them with a snap and vigor that is refreshing.

There is not a speed trap nor horn trap in Montgomery County, despite the fact that there are three big automobile factories located in it or close to it. Such a thing as an arrest for careless driving or speeding is almost unknown, and, by the same token, accidents are exceedingly and gratifyingly rare.

The underlying reason for these conditions is the perfect understanding that has been worked out between the Norristown Automobile Club and the authorities. One might imagine that such a statement meant that the authorities overlooked violations of the law and were remiss in their duties, but as a matter of fact the secret of the situation is the terse principle upon which the club works. As stated by its President, John H. Rex, this is: "Always remember that the education of the public includes instruction of one's self."

The club has a fine home situated on the Ridge Turnpike Road, and equipped with everything adequate for comfort, entertainment and recreation. It is presided over by Julius L. Ernotte, steward, the only paid employee or officer of the organization. There are 275 active members, and recently an arrangement has been entered into, between the club and the Century Motor Club of Philadelphia, by which the members of the Norristown organization have been taken into the Century as associate members, and those of the Century were made associates of the Norristown club. This arrangement is advantageous for both, as the Century has a magnificent clubhouse at Broad and Oxford streets, Philadelphia, while the Norristown Club will be an excellent country club for the city men.

In a sporting way the Norristown club occupies a prominent position. Its first road run was given in 1908 and occupied one day to Lancaster and return. This proved a success, and in the fall of that year a hill-climbing contest was given on Skipback Hill, one of the stiffest and most trying in the vicinity.

Last year the club gave a two-day run to Hagerstown and return, in which 52 automobiles participated. The route and conditions were particularly trying, and the inspection and checking systems put into effect by President Rex and Secretary William B. Hart were of such a nature as to add greatly to the honor of winning the race. These conditions were very strict and were enforced to the letter.

"We figured," said Mr. Rex, "that the value of endurance runs lay in exposing structural defects and mechanical errors in the cars themselves, as well as in demonstrating their good points. Our rules were framed along those lines, and as a result the winner must be a creditable machine."

On May 18 and 19 the club will put on its fourth event and its third road run. This will be 327 miles long and will cover every known variety of going. The out-trip starts from Hotel Montgomery, Norristown, and passes through Reading, Pottsville, Hazleton, Wilkesbarre to Scranton, at each of which places checking stations have been arranged. The return trip will be from Scranton to Stroudsburg, Easton, Allentown, Philadelphia, and back to Norristown.

The club looks for about 75 entries, which will be divided as follows, into two divisions and six classes. The first division is for manufacturers and sales agents. In Class A, cars carrying four or more passengers and valued at $1,901 or over; Class B, four or more passengers, cars valued at $1,900 or less; Class C, two or three passengers and cars listed at $1,501 or more; and Class D, carrying two or three passengers and valued at $1,500 or less. The second division is to be composed of members of the Norristown Automobile Club and other clubs affiliated with the A. A. A. and the non-contestant class under the new reliability rules.

The special regulations governing the run were something of an innovation and caused much comment at A. A. A. headquarters. This was particularly true of the following clauses:

"Between the checking stations each car may stop for a total elapsed time of ten minutes and no more without penalization, provided no repairs or adjustments of any kind whatsoever are made during the time elapsed, and provided that the motor is kept running. This does not apply to the clause covering tire trouble and adjusting non-skid devices, and is inserted in these rules to prevent excessive speed between checking stations. For example, if a car checks out at checking station "A" at 9 o'clock, and is due at checking station "B" at 10 o'clock, the wheels of that car must be in motion for fifty minutes of that hour, and the car cannot stop for a period of over ten minutes outside of the limits of "B" checking station, and cannot cross the line of "B" checking station before 10 o'clock sharp without penalization for overrunning time."

This rule prevents terrific speeding on good stretches of road for the purpose of advertising, and tends to equalize the chances of all contestants. Another thing required under the rules is a brake gear that will check a car moving backward down a 10 per cent. grade, in fifty feet.

Four fine pieces of plate are offered to winners. They are the McDonald and Campbell Trophy, the McCullough cup, Kelly-Springfield Tire Company's cup, and that of the Norristown Chamber of Commerce.

The club has also done good work in improving the roads. It has been stated that the highway extending from the clubhouse to Norristown was the worst bit of going in the State up to about a year ago. To-day that particular bit of road would take high rank with the best in the country. What has been done there has been done in varying degree throughout the county, and the farmers who have to drive to Philadelphia with produce enjoy the benefits quite as much as the members of the club.

It also acts as host to the poor children of the county when it conducts the annual Orphans' Day celebration at Willowgrove Park, and in a dozen different ways does its level best to popularize the motor car.

Its objects are the welfare of the automobile; education of its members to the rights of others, so that good legislation may be secured; co-operation with the local authorities to maintain the law and to promote sociability and good fellowship.

The club was formed in 1907 on a basis of nominal dues. It reached a membership of 100 and commenced its career of usefulness In 1908 it was chartered under the laws of Pennsylvania, and July 9, 1909, it opened its clubhouse. It now has 275 members paying $10 dues, and within a few months it is expected that some further changes will be instituted that will greatly add to the efficiency of the organization.

John H. Rex, a leading attorney of Norristown, is president and a moving spirit in club activities; Edward C. Meier, Phœnixville, is vice-president; Earl C. Wentz, banker, treasurer, and William B. Hart, secretary of a big woolen mill, is secretary. The prediction is made by the officers that the membership will soon be increased to over 500.

HOW SUNLIGHT DETERIORATES TIRES

ANYONE who has had experience knows that sunlight has a deteriorating effect upon tires. Obviously it is impossible to avoid exposing them to the light when running the machine, but when standing, it is the part of wisdom to favor them in any possible manner. To this end don't leave a car standing for hours where the hot sun will strike it—if you do you may find a flabby tire on your return, as an immediate result, with the ultimate ill effect not so readily overcome. It is far better to stop in the shade and walk a hundred feet to your destination.

And in the case of the car that is run mostly at night, it should be covered through the bright hours of the day when in the garage. The man with his private garage can obtain this protection by providing heavy shades for the windows. Sections of old carpet or rugs are excellent for this purpose.

Some short circuits are exasperatingly hard to locate—so much so that many a car has been rewired because of inability to find one. As a last resort (and sometimes before), start up the engine in the dark and look for a spark that shouldn't be.

It is quite possible to show class in little things; a man who has regard for the niceties of the business does not put a rough forged or cast end of a jack against an axle without a doubled rag or piece of waste intervening.

HOW PRODUCTION PROBLEMS ARE SOLVED

(*Continued from Page* 791)

the manufacture of Brush Runabouts. It will be observed that the tools occupy relatively small space, and a single workman who may not be capable of doing anything else feeds the whole battery, which is devoted to the production of gears.

The tale of speed remains concealed thus far. Fig. 3 will help to illustrate the real story. In this figure the working part of one Fellow's shaper is brought clearly into view, in which it will be observed that the cutter is fashioning five gears at one time, they being G1, G2, G3, G4, and G5, which are fashioned by the multiple cutter tool T1, which is reciprocated in the axle plane of the gears, and given rotation concurrent with the rotation imparted to the blanks in the cutting process. The teeth are thus generated in conformity with the most approved practice, not by a unit method, with a fixed cutter which gashes for juxtaposition faces of two teeth, but by a series of strokes in progression until the whole number of teeth are generated to completion. The gears are clamped between spacers S1 and S2, on the mandrel M1, which in turn is held in rigid relation by the arm A1, which is adjustable in two planes, and is held in its socket S3, being clamped tight by the capscrew S4. When the blanks are clamped into place, the cutter is attached to the spindle and the machine is adjusted for running, all of which may be done within the briefest period of time, the shaper is started, and the gang of blanks have their teeth generated on without further attention of the operator. By having extra mandrels, the operator is enabled to mount blanks upon them while the machines are doing their work, and owing to this facility, a single operator is enabled to keep a gang of Fellow's shapers in substantially continuous performance, each one of which is doing five or more gears at one time, and in this way speed is accentuated to the maximum, whereas accuracy is absolutely independent of the man, and is the maximum attainable, due to the qualities of the tool employed.

There are many examples of gear shapers, planers, and cutters, each one of which has its special use, and Fig. 4 is offered as a further illustration of this phase of an important situation. In this a Schuchardt & Schutte type of Pfauter gear hobber is working on the balancing gear, which is used in the Brush Runabout motor to compensate for secondary moments, which are essentially produced in a crankshaft or a single cylinder motor when it is operating at high speed. The balancing gear G1 is mounted on a mandrel, which in turn is fastened to the platen by means of an extension E1, and the hib H1 is carried on its spindle in bearings B1, B2, and B3, taking power from a train of gears, the driven member of which is concealed by the housing H2. The hob rotates in its tangent relation to the gear to be cut, and is so adjusted that the teeh on the gear are fashioned in conformity with the demands, with the further advantage that the cutting is a continuous process, progressive in its character. In this type of tool, while it is true that but one gear can be cut at one time, it is worth noting that the speed of cutting is at a high rate, and a workman may feed a whole battery of these tools so that the labor item is reduced to a minimum basis.

In gashing beveled gears, the idea of ganging the work is a relatively new one, which was brought about on account of the desire of automobile makers to expedite the work, and at the same time add materially to the accuracy, which latter consideration was an absolute necessity in view of the modern idea *i. e.*, noiseless performance is the first requisite. Fig. 5 shows how this situation is satisfied in the production of Brush Runabouts, in which a Carter & Hakes Lincoln type miller operates upon three bevel pinions simultaneously with fixed gashing cutters C1, C2, and C3, in suitable relation with the pinions P1, P2, and P3, they in turn being on spindles S1, S2, and S3, which are rotated for the spacing of one tooth at a time by means of a multiple dividing head, which is housed in the case C4. The gashing cutters are packed on a spindle S4, and are driven by a train of gears.

For the accurate generation of the teeth of beveled gears, which is the final process after gashing, Gleason, Bilgrim, or other suitable equipment is employed. With a view to a sufficient elucidation of the complete process, considering the gashing equipment as shown in Fig. 5, Fig. 6 is offered presenting a Gleason planer, which is shown in the process of generating the correct conformation of bevel gear teeth, and the gear G1 is shown in the chucking fixture C1, in its correct relation to the generating cutters of the tool proper, and the divers means by which the work is fed to the cutters for the purpose of generating theoretically correct teeth show in the illustration.

THE HEAVIER WORK REQUIRES DIFFERENT TREATMENT

Thus far, the principle of rapid production along accurate lines has been illustrated by means of automatic machine tools working on symmetrical and relatively light parts. That the idea is limited to work of this character, however, is not demonstrated by the facts, and Fig. 7, which was taken in the plant of the Regal Motor Car Company, is offered for the purpose of depicting a method of rapidly and accurately rough-boring cylinders. A twin cylinder C1 is mounted in a fixture F1 on the platen P1, of a double spindle vertical mill M1, and the spindles S1 and S2 are equipped with multiple cutters C2 and C3, which are guided into the cylinders by the bushed holes which register therewith. The whole process is rugged, accurate, and speedy. the fixture is quickly mounted into place, and finds its registering position in the absence of any great skill on the part of the operator who has merely to so place the fixture that the pins P2, of which there are two, may be inserted into place.

Fig. 8 is another Regal idea, in which a Wormer milling machine of substantial construction is fitted with multiple cutter straddle mills S1, S2, S3, S4, and S5, which are mounted on a mandrel M1 and so properly spaced that they face off the main bearings M1, M2, M3, and M4 of the crankcase C1, which is clamped to the platen P1, by means of C clamps C2, etc., of which there are four. The straddle mills rotate at the desired speed in the process of cutting, and the work which is clamped to the table, or platen, feeds across at the right speed for the purpose. This method has all the accuracy of the tool room, the speed which comes from the utilization of stout tools, and the main bearings are faced off at both ends simultaneously with the caps in place and bolted down, so that the speed which is obtained is not at the expense of accuracy in any way, nor is the workman personally relied upon for anything but his ability to feed the machine and watch it do the work.

The multiple spindle drill idea has been developed to a high state of perfection since the advent of the automobile, and Fig. 9, which was taken in the Regal plant, shows one of its possible applications; the upper half of the crankcase C1 rests on the platen P1, excepting for the intervening blocks B1 and B2. The multiple spindle drills are guided by the jig G1, and they feed downwards against the work by motion of the housing J1, and in the present case six of the drills are actually working, although any number up to as high as twenty-four are employed under varying conditions of automobile work.

Fig. 10 shows a vertical multiple spindle drill as used in the Regal plant, with one of the spindles S1, and a reamer R1, in its socket, guided by a jig G1, reaming the large end of a connecting rod C1. The jig is so contrived that the connecting rod may be put into place and locked speedily by the workman. and it may be freely moved around the platen P1 as the occasion requires. There are several of these spindles, and the work passes from one to the other in rapid succession so that the process is substantially continuous, and the accuracy of the work done is that which is fixed by the care with which the tools are sized in the tool room, quite independently of the skill of the workman in the finishing process.

Crankshaft finishing, in view of the high quality of the steel used in these members, and the accuracy demanded in practice, is something of a problem which only bows to intelligent treatment. The drop forgings are first rough-machined in a special crankshaft machine designed for the purpose, and they are thereafter set up in a suitable grinder, where the pins are brought down to the finished size. Fig. 11 presents a Landis grinder in the Regal plant, working on a Regal "30" crankshaft C1, and the big grinding disc G1, is reducing the middle main bearing of the crankshaft to a perfectly round and predetermined diameter. Water is fed to the grinding disk through the pipe P1, thus maintaining the temperature substantially constant, and it is a well appreciated fact in shop circles that grinding is not only rapid, but it has the special facility of finishing the pins to a round diameter. In turning work, as it obtains on a lathe, a perfect round is not obtained, and it is easy enough to see that a journal, if it is fitted to an elliptical pin cannot deliver satisfaction. Grinding, in view of this fact, is essential to success.

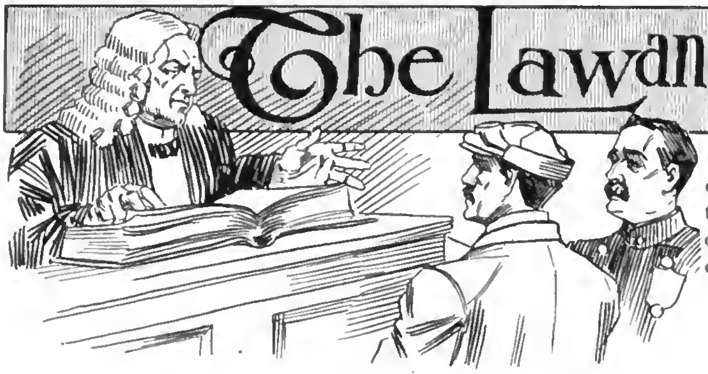
Conventional types of machine tools as they obtain for work in general are scarcely adequate from a specialist's point of view, as Fig. 12 very clearly indicates. This multiple spindle milling machine, which was designed for boring cylinders of the Everitt "30" made by the Metzger Motor Car Company, of Detroit, has four boring spindles, which are so centered with respect to each other that they register with and bore the four cylinders in the block casting C1, notwithstanding the fact that the top half of the motor case is integral with the block of cylinders. The casting is placed with the cylinder head down on the platen P1, and the spindles in their bearing housings H1, are rotated by means of a train of gears taking power from the cone pulley C2, and the belt which rolls over its periphery. The platen of the tool feeds the work up against the spindles, and this, it will be remembered, is the reverse to the customary method. By means of this special tool, this particular shape of motor casting, despite its tendency to complication, is finished expeditiously and accurately, so that in the long run, the motor becomes one of the most simple that it is possible to design.

Covers for cylinders and hand-holes in motor cases were considered very difficult of finishing up to the time when the flat grinder came into vogue. Fig. 13 presents the flat grinder idea, in which the covers C1, C2, etc., are placed on a magnetic chuck M1, and the grinding disc G1 is lowered down until the grinding face is in proper relation with the faces of the covers to be finished, when the platen of the grinder P1 feeds back and forth in the plane at right angles to the axis of grinding. The magnetic chuck holds the work, and the operator is enabled to change over after the grinding is completed in a few moments so that this character of machine tool has an enormous capacity, and the finished faces are to greater accuracy than is possible of attainment by a milling process, or if a planer or shaper is used for the purpose.

Grinding is one of the truly important processes in the modern shop, and Fig. 14 shows another meritorious application of the principle. In this case, piston rings P1 are first machined to near size, and then placed on the magnetic chuck C1, when the grinding disk D1 performs the finishing operation, first on one side of the rings, and then upon the other. The magnetic chuck enables the operator to lay the rings upon the face of the chuck and to immediately throw the traveler into gear, and by previously fixing the distance between the face of the magnetic chuck and the grinding disk, considering the design of the tool, the work proceeds substantially automatically, and the capacity of the two is very great. Accuracy is one of the assured conditions, and interchangeability follows, since the tool works within close limits day after day.

Vertical milling machines of a very massive type are coming into vogue for divers important operations, and Fig. 15 presents one version of this idea, in which the cylinder C1 is having its faces milled by the multiple cutter M1. The cylinder rests on the traveling platen T1, by means of which work the work feeds across in its correct relation to the multiple milling head and accuracy as well as speed is realized in practice.

The Law and the Automobile



REGISTRATION NOW PENDING IN KENTUCKY

Kentucky motorists are deeply interested in the automobile State registration bill, which is now pending before the Legislature, providing for the registration of automobiles with the Secretary of State. The bill is similar to that adopted by many other States throughout the country. The chief item of interest in the measure is that providing that a certificate of registration of any other State shall be considered a license for a car owned by motorists in another State to pass through Kentucky, provided a similar privilege is accorded Kentucky-owned and licensed vehicles in the States concerned.

Owing to the fact that a city license is not recognized in most other States, it is now necessary for automobilists whose cars are registered in any city in Kentucky to secure a permit from the Secretary of State or some other official after leaving the State. House bill 272 provides the registration with the Secretary of State and a fee of $2 per car for such registration. Its speed regulations are ten miles per hour in the business districts, 15 miles in the residence portions of cities, and 20 miles per hour on the public highways. A fine of $20 to $50 is provided as a penalty for violation of the act. This act will repeal all laws and acts inconsistent with it.

FREE RIDE FROM NEW YORK TO BOSTON

Boston, Apr. 18—Anybody who wants a free automobile ride from New York to Boston can simply engage a taxicab—that is, if the taxicab driver will accept the engagement after he learns the destinations. The Supreme Court of Massachusetts recently decided that no law compelling patrons of taxicabs to pay for their rides exists on the statute books of the State.

However, the New England manager of an automobile concern is anxious to find the supposedly wealthy New Yorker who engaged a taxicab at Seventy-ninth street and First avenue, New York, for a ride to Bridgeport. The man spent money freely, and the chauffeur made no objection when the trip was extended to Boston. But at Waltham, Mass., a few miles from the latter city, the stranger disappeared through the back door of a hotel, leaving the chauffeur waiting outside, with the sum of $171 registered on his taximeter.

NEW YORK AUTO BILL PASSES HOUSE

Albany, Apr. 20—With only three votes against it, cast by Mr. Lansing (Rep., Rensselaer), Mr. Lee (Rep., Kings) and Mr. Gray (Rep., St. Lawrence), the Assembly passed the Automobile bill, handled in the lower house by Assemblyman Allan S. Callan (Rep., Columbia). This is the measure which makes a general speed limit through the country of thirty miles an hour; gives the three cities of the first class, New York, Rochester and Buffalo, the right to make their own traffic regulations; provides a speed limit of fifteen miles an hour in all second and third class cities and villages, and a registration fee to be paid to the Secretary of State at the rate of $5 for cars of 25-horsepower or under; $10 for cars between 25 and 35-horsepower; $15 for cars between 35 and 45-horsepower, and $25 for all machines above the 45-horsepower class.

"FARMER" DUNN GETS CAR AND COIN

Far-reaching in its purview is a decision rendered recently by the New Jersey Supreme Court in the case of Elias B. Dunn against the Greenhalgh Engine and Machine Works, of Newark. Mr. Dunn ordered some repair work upon his car and the parties agreed to a price for the work. After several tests, Mr. Dunn reported that the car did not work properly and the company declined to allow the machine to leave its possession until its bill, which exceeded the agreed price, was paid in full. The court decided that the company was in the wrong and the jury not only awarded the possession of the car to its owner, but also gave him a verdict of $1,032 as damages for its unlawful detention.

NEW KENTUCKY LAW IS POPULAR

It is estimated that Kentucky will receive $25,000 a year from the automobile tax which will become effective June 14. At present there are about 3,000 automobiles in the State and the number is increasing steadily. The majority of the motor cars are in Louisville. The tax is graded according to the horsepower of the cars and will range from $5 to $10 and $15 a car. Automobile owners favored the law as it will give them a better standing and the protection of a State license. The speed laws were also changed to their liking.

MORE POLICE TO WATCH N. Y. SPEEDERS

To stop speeding by automobiles in the outskirts of New York City, sixteen bicycle policemen have been added to the force in the Bronx by Commissioner Baker. This is the result of several fatalities and serious accidents during the past few weeks. The six motorcycle men who formerly made up the whole speed squad of the Bronx will henceforth pursue speeders on upper Broadway, Pelham, and Riverdale avenues.

TESTERS MUST PAY LICENSE FEE

Detroit, Apr. 18—According to an opinion rendered by Attorney-General John E. Bird, an automobile tester comes under the same ruling as a chauffeur in Michigan, with the result that he must pay a license fee of $2, this being merely a nominal sum imposed for the purpose of giving the State control.

ROAD BUILDING NEWS

WILL ABANDON ROAD MAP WORK

Detroit Automobile Club will continue as a family country club, maintaining its present delightful quarters at Pine Lake. This action was decided upon at the annual meeting, sentiment being unanimous in favor of leaving touring and road map work and the maintenance of a city club to other organizations. This does not mean that the club will lessen its activities.

E. A. Skae, Frank H. Whelden and Sherman L. Depew have been elected to vacancies on the board of directors, to serve three years.

Commissioner H. L. Bowlby of the Washington State Highway department has authorized an expenditure of $2,000 for the improvement of one mile of road between Asotin and Cloverland.

Recent Club Activities

HARTFORD CLUB ELECTS OFFICERS

Hartford, Apr. 25—The annual meeting of the Automobile Club of Hartford was held at the club quarters in the Allyn House and the following officers elected: President, C. H. Gillette; vice-president, Arthur G. Hinkley; secretary, Phillip E. Curtiss; treasurer, C. De Lancey Alton, Jr. The chairman of the various committees were appointed as follows: House, Albert M. J. Kohn; Membership, Fred W. Dart; Contest, H. P. Maxim; Good Roads, Ralph D. Britton; Rights and Privileges, Colonel George Pope.

C. H. Gillette, the new president, was vice-president of the club two years ago and has always been an active worker in the organization, especially on the contest committee. Arthur G. Honkey was secretary during the past year. Phillip E. Curtiss is a newspaper man and was recently elected secretary of the Connecticut Automobile Association. The report of the secretary shows a membership of 337. The total receipts for the year were $4,334.77, while disbursements were $4,287.04.

CLUB WILL INSIST ON ROAD ETHICS

The Outagamie Automobile Club is a new county association of owners formed at Appleton, Wis., by thirty prominent citizens. Frank J. Harwood was elected president. The other officers are: Vice-president, Charles Hagen, of Black Creek; secretary and treasurer, P. M. Conkey, Appleton. Directors, Samuel J. Ryan, M. F. Barteu, Jacob Wolf, Dr. Laird and Sam Whedon, of Appleton; Dr. Charles Boyd, of Kaukauna; Arthur Miller, of Seymour; A. K. Dewick, of Shiocton, and A. Heller, of Hortonville.

The constitution and by-laws lay particular stress upon the object of imposing penalities upon members violating the rules of the road and conduct detrimental to the motor car's best interests. The club will affiliate with the Wisconsin State A. A. and thus with the A. A. A.

CLUB ACTIVITIES IN TWIN CITIES

Minneapolis, Apr. 25—The Minneapolis Automobile Club held its annual meeting recently and the following officers were elected: President, George M. Gillette; first vice-president, H. J. Clark; second vice-president, Charles D. Velie; secretary, G. A. Will; treasurer, Louis Koch.

The membership of the club has increased 55 since a year ago and the treasurer's report showed a surplus of $6,389.51.

At a meeting of the board of directors of the Minnesota State Automobile Association in St. Paul, April 7, definite plans were made for the installation of sign posts along the main traveled thoroughfares throughout Minnesota. An Indian concern will furnish the posts and install them free of charge. The State association will pay for the standards.

BLUE GRASS AUTO CLUB IS ORGANIZED

Permanent organization was effected by the Bluegrass Motor Club at a meeting held recently at the Phoenix Hotel, Lexington, Ky. The following officers were elected: K. G. Pulliam, president; E. H. Alexander, vice-president; James S. Helm, secretary; W. S. Viley, treasurer.

The following board of governors was also elected: K. G. Pulliam, James S. Helm, W. S. Viley, E. L. March, Alex Morgan, C. E. Lyons and Dr. H. H. Roberts. The club has a membership of 100, which is expected to double within a few months.

The club expects to have steel mile posts and guide signs placed on all automobile routes in the central part of the State.

LOUISVILLE CLUB WILL BUILD

The annual meeting, banquet and election of the Louisville Automobile Club was held at the Seelbach Hotel. The following officers were elected: President, Eugene Straus; first vice-president, L. H. Wymond; second vice-president, Hewitt Brown; secretary, Dr. R. Lindsey Ireland, and treasurer, Walter Kohn. Kohn and Straus were re-elected. In his annual report President Straus announced the preparation of plans for the construction of a clubhouse and garage in the central section of the city. The proposed building calls for an expenditure of $25,000, which it is proposed to raise by the sale of stock.

PHILADELPHIA CLUBS PREPARE TO TOUR

Philadelphia, Apr. 25—The Century Motor Club is planning a sociability run, which will be a leisurely affair based solely upon enjoyment. Two-hour dinner control and secret checkers will be two of the details of the arrangements. The exact date has not yet been selected.

Both of the ladies' automobile clubs are also planning annual outings. That of the Quaker City Ladies' Motor Club will probably come first, followed by that of "La Movigante Klaubo," which is quartered in Colonial Mansions in Fairmount Park.

CLUB PLEDGED TO IMPROVE ROADS

Owners at Manitowoc and Two Rivers, Wis., are organizing a club, one of the objects of which is to improve country roads and to raise funds for placing sign boards in Manitowoc county. Both cities are objective points of many parties during the touring season. J. E. Hamilton, millionaire manufacturer of Two Rivers, is slated for the presidency, and Edward J. Carroll, manager of a hotel at Manitowoc, will be secretary. About 100 members will sign the charter, it is expected.

SHOW BREVITIES

EASTERN MAINE AUTO SHOW

Bangor, Me., Apr. 20—Under favorable auspices, the second annual automobile and motor show of Eastern Maine will open Saturday evening. Extensive preparations have been made, and the management is confident that the affair will be successful from every viewpoint. The show will be held in the Auditorium and will continue until April 29.

HARRISBURG SHOW A SUCCESS

Harrisburg, Pa., Apr. 18—The recent exhibition held under the auspices of the Harrisburg Dealers' Association proved to be a glittering success. One of the developments and results of the show is the emphasis laid upon the need of a large building in which to house the future events of this character.

Difficult Carbureter Adjustment

Editor THE AUTOMOBILE:

[2,240]—I have a light runabout, using a * * * carbureter. How would you adjust it to give the most power? It goes well at high speeds with the throttle open three or four notches, but seems to choke up if the throttle is opened over one-half. Your answers to inquiries about carbureters that have springs on the air valve do not apply in this case. Would it pay me to jacket the exhaust pipe and carry hot air to the inlet of the carbureter

Mooers, N. Y. CARBURETER.

It is difficult to understand how a carbureter of to-day can be made and used without an air adjustment. If the carbureter in question has one, the adjustment of it goes as follows: Run the engine at its highest possible speed, and vary the air adjustment while so running to give all the speed possible. By varying the adjustment while the engine is running you will discover whether the result is favorable or otherwise. If favorable continue until the high point is found, while if unfavorable, turn in the opposite direction until the desired result in secured. Having adjusted this until the maximum possible speed is obtained, slow the engine down as slow as possible, then adjust the gas line feed so as to give the lowest possible number of turns per minute of the engine. This, too, will be found by experimentally turning in both directions. When the very slowest speed is found and fixed as to adjustment, and the same as to the high speed, the carbureter is said to be adjusted. Beyond this work, the only thing that can be done is in the nature of very slight additional changes which would be made on the road, to give slightly more or less speed, or more power at slower speed.

Now that warm weather is coming on, it would hardly seem advisable to go to the trouble and expense of supplying the carbureter with either hot air or hot water, which is essentially a cold weather provision, making vaporization more easy at that time.

There are, however, many makers who fit a source of heat to their carbureters even for summer use.

Cast Iron Welding

Editor THE AUTOMOBILE:

[2,241]—I have a Packard '06 car, but unfortunately have cracked the water jackets of both cylinder units. In one cylinder the crack goes through the cylinder wall proper. The break is very small and collects about half a cup full of water when the car is at rest. Could you recommend some firm which could weld the cylinders successfully? I should be much obliged if you would do this, as no one around here seems to know much about it.

Rhinebeck, N. Y. H. M. SUCKLEY.

The success or failure of the welding process will depend somewhat upon the nature, size and condition of the break. If small, not opened up very wide, and with rough edges to help the welding material adhere, the job will doubtless be successful. This art of welding cast iron has advanced so much in the past few years that in your particular case it is well worth trying before purchasing new cylinders, which would be somewhat expensive. The best plan would be to bring the cylinders in to New York City, where there are many firms doing this kind of work. To mention a few of them: Davis-Bournonville Company, West Street Building; Industrial Oxygen Company, Hanover Bank Building; Schaap Flame Utilities Corporation, 344 Cumberland avenue, Brooklyn; National Electric Welding Company, 181 Christopher street.

Valve Sizes and Relative Importance

Editor THE AUTOMOBILE:

[2,242]—I should like to ask your opinion about the valve sizes and lift in modern automobiles. Are not the size and lift of valves an important function of gas engine efficiency; almost as important as cylinder bore and stroke because of what use are large cylinders if they cannot be completely filled and emptied with each explosion? The effective power of various cars will vary widely with the same cylinder displacement, and while there are many elements contributing to the efficiency of gas engine power, it seems logical to believe the valve details are a most important item.

All details of engine construction are widely advertised as an essential in rating the car except the valve construction, and these records are very rare. In fact, it seems to be a carefully guarded detail with many makers. At both the New York Automobile Shows every maker would tell you all about the cylinder bore and stroke, about the crank, pistons and engine with perfect freedom of knowledge, but when you come to valves they simply are ignorant or cautious. Some would guess at it, others did not know. Foreign makers were frank enough to say it was none of your business, you could buy a car and measure it. Why is this such a mysterious secret?

The quick rejection of hot gases through ample exhaust valves is a most direct means of reducing heat in cylinders, and the cooling system would be designed in proportion and yet they consider this unimportant. It is generally understood that engines for high speed work must have extra large valves, and if so, why would the same valves be undesirable for ordinary work. Manufacturers may feel a hesitation in letting competitors have the information and think the ordinary layman has no business with it. This is a great perod of mechanical study, it is universal, and the layman is really the buyer. The purchase of a new car is a very important expenditure for many and it is natural that he should want to feel that his new car is reasonably proportioned for his use.

Many manufacturers will say that their engineers know their business and that their cars are always satisfactory, but satisfaction in a car is more or less a matter of degree based upon previous experience in a comparative sense. A person could easily buy a 50 horsepower car with too small valves and express general satisfaction, in perfect ignorance of what the same car would do if properly proportioned throughout. It may compare favorably with the old car he has just gotten rid of, and yet he will calmly explain that he does not care for speed when he swallows dust from many 20 and 30 horsepower cars, and he will continue to maintain his position that he has not been "stung."

This is a matter that should be scientifically proportioned from practice, and it seems to me an evidence of lack of confidence when a maker will dodge giving this detail about his own product. I would like to hear your opinion and I would like to hear manufacturers explain their ideas of valve importance, just for general information. D. C. N. C.

New York City.

In the beginning and even right down to this day valves were proportioned to the speed of gas flow allowable and the quantity of gas to be passed through the valve. Thus, a lineal dimension as speed in feet per minute times a fixed area results in a volume that is, the volume of the gases. In the case of the inflowing gases this volume is fixed by the cylindrical capacity of the cylinder to be fed, but in the matter of the heated and expanded exhaust gases the volume cannot be determined so accurately.

So it is that the latter has always been a guessing point. When a manufacturer has guessed right, and proved it by actual results, he is not usually willing to give this advantage away to his competitors. More than this, the starting point, the allowable speed of the gases is a sort of guessed-at point, which is being constantly revised, so that the whole design of valve ports and valves is somewhat shrouded in mystery.

Later engines have shown that for any given figured area of port, taken in conjunction with the speed and valve lift to give a predetermined volume, there were two matters which could be varied with varying success. Thus, the older engines had high lifts with small valve ports. Lately, it has been found that superior results could be obtained with larger valve openings and lower lifts. the net area or volume being the same. The extreme speeds now obtained in racing cars is in part due to this fact, and the universal recognition of it, but the makers who found it out by costly experimentation were not the first ones to publish that fact.

Unequal Wear of Two-Cylinder Engines

Editor THE AUTOMOBILE:

[2,243]—Will you please answer the following question: Will the front cylinder of a two-cylinder gasoline engine wear out of round owing to the different angles of the connecting rod and crankshaft on the firing stroke? HAVENS BROTHERS.

Ladoga, Ind.

If the above question is understood correctly, reference is had to a nearly obsolete form of engine, in which the crankshaft was set across the axis of the car, so as to have a straight line chain drive from the transmission located on the crankshaft to the rear axle. In this form, the load on the springs, when fully applied, lowered the rear end of the engine so that it set at a slight angle to the horizontal. This condition is only possible with this location of the engine, since with the engine placed across the frame, that is, with the crankshaft axis parallel to the axis of the car, as is the usual case now, this could not happen. Both cylinders would then be depressed equally.

In the case under consideration it is believed that the cylinders would wear slightly out of round in any case, purely from the nature of the situation, that is, the natural tendency to wear would be augmented by the force of gravity. This, however, would be effective in the case of both front and rear cylinders, and that any additional action would take place in the front cylinder is to be doubted. in fact, it would seem as if the rear cylinder would depart more from a horizontal line than would the front one. This is because the rear end of the chassis would come down under the load more than the front. The whole action is nearly negligible.

Age No Bar to Chauffeurs

Editor THE AUTOMOBILE:

[2,244]—Will you kindly consider the following and give me your opinion in "Letters Interesting, Answered and Discussed?" I am a boy 16 years old, of medium height and weight. I have had experience driving automobiles for the past five years, during which time I have driven them for thousands of miles. I have also taken care of them and done repairing. Would you think a person as young as I am could obtain a position as a chauffeur in the summer months on extended tours? S. M. J.

Middlefield, O.

Age should be no bar to employment as a chauffeur, either on extended tours or otherwise. If a man can prove his worth as a driver there should be no question as to his age. If your mechanical ability is such that you can handle cars, repair them, and generally take care of them, age, height, weight, color, nor previous condition of servitude would be no bar to your obtaining and holding a good position as a driver. Several of the prominent racing drivers now before the public are but 18 years old; surely if these boys can manage a racing car, a chap but two years younger can handle a car under less strenuous conditions.

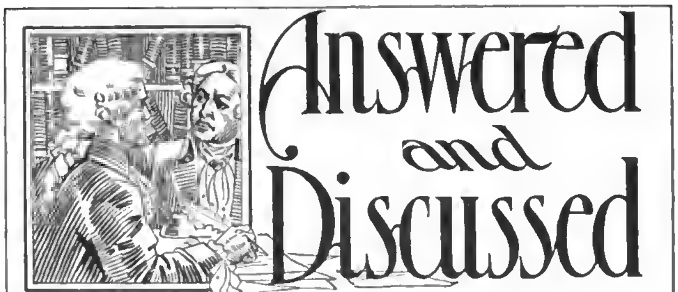
Cannot See Very Well

Editor THE AUTOMOBILE:

[2,245]—I wish to call your attention to letter number 2,169, February 17, 1910, issue of "The Automobile," in which you state that a full description of the Keystone car is given in the issue of July 15, 1909, page 109. I cannot find the Keystone car mentioned on that page or in that issue. Please let me know through the columns of "The Automobile" where I can find a description of that car. A SUBSCRIBER.

Zanesville, O.

On page 109 of the July 15 issue of THE AUTOMOBILE for 1909, Volume 21, the entire page is devoted to the Keystone car. This page shows a special head of the car in question, marked "Keystone Six-Sixty," following which are some 1,000 words descriptive of the car, ending with a picture of the engine, labeled "Keystone Six Engine Has Two Separate Exhaust Pipes." The writer above could never have looked at the right page, or he would have the story in question, as it occupies the whole page to the exclusion of everything else.



Danger of Breaking Crankshafts

Editor THE AUTOMOBILE:

[2,246]—Will you please answer the following questions through the columns of "The Automobile," of which I am a subscriber and interested reader: Is there any danger of breaking or injuring the crankshaft of a four-cylinder engine having only two or three plain bearings by starting it on the battery without cranking it over? It seems to me that this puts a great pressure on the crankshaft while it is not in motion. Can you tell me of any cement or anything of that kind to stop small cracks in the cylinder walls? It is a very small crack, just enough to allow the water to seep through to the inside after it has stood for a long time. F. L. S.

Del Rio, Tex.

While the starting strains on a crankshaft are severe they are no more severe than the strains set up in pulling through deep sand, in climbing a steep hill with a retarded throttle and in many similar circumstances. Even if these strains were more severe it would be a poor make of crankshaft which did not have incorporated in its design a sufficiently large enough factor of safety to take care of these strains and still leave the shaft safe.

Elsewhere in this issue, you will find a car description, in which is given a reproduction of the working drawing of a crankshaft, with dimensions, finish marks, and everything necessary. A study of this, in comparison with the size and rated power of the engine, will soon convince you that the makers know what they are about in the matter of crankshaft sizes and proportions.

Very small cracks in the waterjacket, such as you describe may be fixed by putting into the water circulating system a small quantity of Sementol, a preparation made by the Northwestern Chemical Company, Marietta, Ohio. There are probably other similar preparations made.

Gear-Grinding Noise and a Remedy

Editor THE AUTOMOBILE:

[2.247]—Will you kindly explain through "Letters Interesting, Answered and Discussed" in your very good paper, what is the matter with the transmission gears in my model E Jackson car? The same has been noisy ever since I received the car, and after driving it about 800 miles developed a knock which was very noticeable on first and second speed, and even when not in either, but upon third could not be detected. I thought the jackshafts were loose and returned the same to the factory as per their request, but they inform me that such is not the case, but want to replace the gears because the same are slightly battered and chipped. Now, they are so very slightly battered and chipped that I don't see how they could have caused the continuous noise and the knock which developed, but has not grown worse. Kindly let me know your ideas in this puzzling case in regard to the trouble, as I cannot agree to their proposition. C. B. ISLEY.

Attica, Ind.

In a case similar to this, but which concerned another car, the transmission being located on the rear end of the unit power plant, the factory engineers stated that the principal trouble lay in the slight lack of adjustment of the bevel gears, which were nearly 30 inches away from the transmission suspected of making the noise. Gear noises have often been cured for good by a change of lubricant, such as the substitution of a heavy grease for a light one, or grease with graphite for grease without, or even in one case, of sawdust with graphite for all other lubricants. You might try one of these changes and see if it does not bring about a happy result.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

Grinding methods obtain in the plants devoted to the manufacture of automobiles as they never did before, and to an extent so great, considering complex operations, that it is almost a wonder. In these days, camshafts are invariably ground; even the contour of cams are so shaped by grinding methods that they assume great accuracy. This is a matter of more than a little moment; cams, unless they are precisely shaped, are scarcely likely to do good work, and, since they are rendered glass-hard before they go into place, it is obvious that no other method can be used to render them fit on a basis of grinding accuracy.

Crankshafts are difficult to make, unless they are rough machined, and then ground, and it is the common practice of the makers of automobile crankshafts to grind them. Pistons, rings, cylinders, and, in fine, all the parts of importance are ground, but the end is not yet. Gears may now be ground after they have their teeth fashioned and are rendered glass-hard by suitable heat treatment. It is this particular practice, which is the latest addition to grinding methods, that is attracting the notice of automobile engineers. The new grinder, despite the enormity of the undertaking, is proving to be of the greatest possible service; it is so made that after the teeth are approximated in the regular way, using gear cutters at high speed, the gears are hardened and they are then set up in the grinder to be finished.

The new type of grinder is so made that a nest of gears to be finished are pressed on to a mandrel and set up under the control of a dividing head. The dividing head rests on a table which is provided with a feed, and the teeth of the gears are passed along so that the grinding disk of the required shape takes off the requisite amount of metal from the teeth to bring them down to a true shape and to the right size. That the grinding disc would soon wear out of shape is well appreciated, and in order to avoid this, it passes up against a diamond cutter each time a cut is made over the teeth of the gears so that the shape of the grinding disc is corrected as rapidly as wear tends to reduce it from the standard set. The tool is automatic within limits, has a large capacity for work, and the gears finished by this process are so precise that they mesh perfectly on the pitch line and run without any noise at all. That this is the greatest advance in automobile construction, for at least a year, is quite plain, and it represents one of the grounds for assuming that the automobile of the future will be a most perfect device.

Predictions are frequently made that the automobile is now up to its limit of development; these prognostications come from users of some judgment; they are based upon experience, but they are not necessarily true. In order to be able to judge of the future, it is necessary to visit the makers of automobiles and see what they are doing. Men who devote their lives to the perfection of automobiles are too much in earnest to stand still; advances are bound to be made; if a convict can break out of a stout jail, despite the fact that he is being watched day and night, it is not too much to expect of men of great intelligence, that they will break out of trouble when it confronts them. Scarcely a month goes by without recording some noteworthy advance in the process of manufacturing automobiles, and the troubles of yesterday give way to the victories of to-day.

* * *

Testing automobiles as they are manufactured in a large plant devoted to the purpose is a problem which has to be coped with, and that it taxes the ingenuity of makers, is admitted. When an experimenter builds one equipment, be it an automobile or any other generic type of machine, his first concern is to test it and ascertain what it is good for. If one machine must be tested after it is made to determine its competence, remembering that it is made under the eye of the designer, how can it be that 20,000 machines can be built and placed at the disposal of ultimate users with assurance that each one of them will be all right, if they are not tested. It might be the claim that after the first machine is made and found to be in good working order, all the remaining machines may then be taken on trust despite the fact that the designer cannot spread himself out so thin that he will be able to give each one of them the benefit of his skill and judgment.

Experience has never shown that machines can be so well made that they may be turned out in vast quantities, even allowing that all the parts be carefully inspected, and never have occasion to make further adjustment after the machines are completed and started. The amount of attention that each completed article must receive may be but slight, but it is ruinous to a reputation to disregard this difference. The amount of expert attention required will decrease in proportion as process testing is resorted to.

First Annual Up-State Relay Club Run

MAY 28, the first annual Central New York Relay Club Run will leave Syracuse, New York, carrying messages from prominent men and officials of the National and State automobile associations, which will be relayed from club to club by the participants in the run. The messages will be relayed through Auburn, Cortland, Ithaca, Watkins, Elmira, Owego, Binghamton, Oneonta, Cooperstown, Richfield Springs, Utica, Rome, Oneida, and back again to Syracuse.

The arrival of the tourists in each place will be made the occasion of an informal entertainment, with the local club as host, at which the messages will be read, an interchange of views had on important subjects, and a good time enjoyed.

In order to add zest to the event, a secret time within the speed limits for each lap of the run will be set, and the car making this distance nearest the secret time will be given a prize donated by promoters of the run. An E-M-F "30" touring car was selected to lay out the route. The official pathfinder left Syracuse Saturday morning, and is expected to occupy a week.

The run will require four or five days, and the dates have been arranged so that they come not only at the season of the year when the country is in its prettiest garb, but also to include three holidays—Saturday, Sunday and Memorial Day.

NEW CLUBHOUSE FOR BUFFALO CLUB

With a burst of enthusiasm, the Buffalo Automobile Club raised $11,020 in less than an hour as the nucleus of a fund to be used to build a clubhouse at Clarence Hollow, seventeen and a half miles from Buffalo on the Main road. This action was taken at a smoker which was held in the temporary clubrooms in the Teck Theater.

The club has acquired a tract of seventy acres of land and the structure will be in colonial style of rough base-boards and stucco decorations. Plans and drawings were exhibited by Lawrence Enos, president and Robert Cartere, architect.

The whole expense of the project will be in the neighborhood of $75,000 and a bond issue has been authorized to raise the money. It is expected that the clubhouse will be ready for occupancy by July 1.

The bonds will be issued in two denominations, $10 and $100, and the whole amount of the fund, it is expected, will be raised within a few weeks among the club members.

WILL BUILD BIG BATTERY PANT

Storage batteries and other electrical appliances will be made on a larger scale at Niagara Falls when the new plant of the United States Light and Heating Company, ground for which was broken recently, is in operation.

The company already has three large factories and is incorporated in the new works. The initial outlay for building will be $300,000 and the plans, as far as they have been completed, include thirteen buildings, covering ten acres.

JOB FOR "GOOD ROADS" MAXWELL

Following the resignation of Charles J. Forbes, Jr., former secretary of the Cleveland Automobile Club, M. M. Maxwell, known as "Good Roads Maxwell," has been appointed to fill the office. He was formerly secretary of the Ohio Good Roads Federation. He was also for several years a writer on Cleveland newspapers.

Coming Events in the Automobiling World

Apr. 23-29........Bangor, Me., Auditorium, Second Annual Eastern Maine Automobile and Motor Show. J. Henry Graham, Manager, Old Orchard, Me.
June 20-July 6....Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.
Jan. 7-14, 1911....New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 17-24, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Feb. 13-25, 1911...Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

Apr. 30-May 2....Philadelphia Roadability Run to Atlantic City, Quaker City Motor Club.
May 5-7..........Atlanta, Ga., Track Races. Atlanta Automobile Association.
May 9-11.........Harrisburg, Pa., Fourth Annual Reliability Contest to Atlantic City and Return.
May 18-19........Norristown, Pa., Third Annual Endurance Run, Norristown to Scranton and Return.
May 19-21........Hartford, Conn., All-Connecticut Reliability Contest.
May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.
May 21-22........Track race meet, Memphis, Tenn. Homer C. George, Manager.
May 27, 28-30.....Indianapolis, Ind., Automobile races including championship events on motor speedway.
May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill; Automobile Club of Bridgeport.
June 4............Worcester, Mass., Fourth Annual Hill Climb, Dead Horse Hill.
June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.
June 12..........New York City, N. Y., Trade Association, Orphans' Day Excursion to Coney Island and Return.
June 15..........Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, through the Southwest.
July 4............Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.
July 30..........Wildwood, Pa., North Wildwood Automobile Club Race Meet and Club Run to Track.
Sept. 5..........Wildwood, Pa., Speedway, Labor Day Race Meet of N. Wildwood A. C.
Sept.............Chicago Commercial Car Reliability Contest of Chicago Automobile Club.
Oct. 1............Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 8............Philadelphia, Fairmount Park race. Quaker City Motor Club.
Oct. 15...........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races.

Apr. 27-28........Brooklands, England, Two-Day Meeting.
May 1-Oct. 1......Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 25...........''The American Cup.'' Argentina, Sociedad Sportiva Argentina, near Buenos Ayres.
May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.
May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.
June 2-8..........Prince Henry (German) Touring Competition.
June 13-18........Scotland, Scottish Reliability Trials.
June 20...........French Voiturette Race.
June 21...........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27...........Speed Trials at Kiev, Russia.
July 12-18........Ostend, Belgium, Automobile Week.
July 20-25........Boulogne, France, Automobile Week.
Aug. 1-15.........Ardennes, France, Meeting.
Aug. 15-Sept. 15..French Industrial Vehicle Trials.
Aug. 21...........Salon, France, One and Five Kilometer Trials.
Aug. 28...........Mont Ventoux, France, Hill-Climb.

MANY ENTRIES FOR QUAKER CITY CLUB RUN

ULTRA-modern—up-to-the-minute in every respect, will be the Third Annual Roadability Run of the Quaker City Motor Club, which starts Saturday morning, April 30, from the rooms of the club at the Hotel Walton, Philadelphia, and traverses the State of New Jersey to Atlantic City.

Indications point to many more than 100 entries and club officers believe that at least 150 cars will make the run. The entry box remains open until Wednesday midnight.

The course is about 68.2 miles long and the finishing line is opposite the Hotel Strand at Atlantic City.

Special arrangements have been made at Philadelphia and Atlantic City and at various intermediate points to police the route of the cars, and elaborate plans have been laid to welcome and speed the contestants at a number of places en route.

The trophies consist of five magnificent pieces of plate and five series of approximation prizes, all of which are well worth the effort of winning.

The unique feature of the run is the "secret time" arrangement by which the prize awards will be made. A plan has been followed in this particular, that is different from any of the usual ideas of a secret time and all that has been announced is that Mayors Reyburn and Stoy have agreed on a time within the New Jersey speed laws and the cars that most closely approximate their figure, will win.

BRIDGEPORT MAY HAVE AUTO TRACK

Plans for an automobile race track at Bridgeport, Conn., have been brewing for some time, and the idea has met with much encouragement in that vicinity. The plan, as most definitely outlined, contemplates the construction of a course back of Lordship Park, where conditions are said to be particularly favorable for such an undertaking.

The Bridgeport Automobile Dealers' Association is behind the tentative plans that have been put forward at this stage.

PREPARING TO TIME ROAD RUN

Details and plans of service for the newly organized Timers and Scorers Club of Philadelphia were discussed at a meeting of that body at the Quaker City Motor Club last Friday evening. The chief matter under discussion was the Third Roadability Tour of the latter club which commences April 30.

Work upon the revision of the system to be used in the coming Fairmount Park race has commenced. The club is seeking some means of improving the score-sheet and blackboard system in use last year and has under consideration two mechanical timers. The club is being drilled with particular care for the big event.

Paul B. Huyette, president of the new club, is a wealthy and enthusiastic automobilist. I. C. Minford, secretary, is the automobile editor of the *Evening Times* of Quakertown.

I. C. Minford, Secretary of the Scorers' and Timers' Club of Phila.

HARTFORD CLUB TO ENTERTAIN

At a recent meeting of the Board of Governors of the Automobile Club of Hartford the following committees were named: House and Entertainment—Albert M. Kohn, Wallace T. Fenn, Frank J. Knox, J. G. Hawley, Louis P. Strong. Contest—Hiram Maxim, Arthur G. Hinkley, Henry W. Nuckols, Albert M. Kohn, William T. Plimpton, Samuel A. Miner, William C. Russell. Rights and Privileges—George Pope, Dr. Harmon G. Howe, Edwin Y. Judd, Walter C. Faxon, Frank J. Knox. Good Roads and Signboards—R. D. Britton, C. D. Alton, Jr., F. A. Morley, John E. Bruce, Samuel C. Doty.

Plans were made for entertaining the selectmen of all the towns in Hartford County as well as the heads of all the granges at a near future date. The club has a number of important suggestions to make to the officers concerning the application of automobile legislation and regulation.

READVILLE TRACK FOR AUTOS

Earnest efforts are being expended to secure the racing plant of the historic Readville race track for a permanent motordrome and aerodrome. The track upon which so many gallant thoroughbreds and harness champions have appeared has seen its last Grand Circuit meeting, and as it has been proven that the track is admirably suited to some forms of motor racing, even in its present shape, the chances appear rosy that it will be taken over, possibly by the Bay State Automobile Association, and used for automobile racing.

STATE AUTO CLUB IN NORTH CAROLINA

With the object in view of forming a State automobile association, a general meeting of North Carolina motorists has been called to assemble at Greensboro, May 9 and 10. The objects to be attained by tentative organization are the furtherance of the interests of the automobile; the upbuilding and maintenance of the roads of the State; the formulation of adequate legislation for the benefit of all users of the highways; the enforcement of the rules of the road and the banding together of automobile owners for mutual protection and advantage.

TEXANS FORM AUTOMOBILE CLUB

With a charter membership of 90, the Beaumont Automobile Club of Beaumont, Texas, was formed recently at an enthusiastic meeting of motor owners of that city. Edward Stedman was chosen president; W. C. Gray, vice-president; S. S. Solinsky, secretary, and E. A. Blanchette, treasurer.

COMMERCIAL CAR CONTEST PLANNED

CHICAGO, April 25—The Chicago Automobile Club's contest board has decided to schedule for early September a commercial car contest in which it will be the aim to demonstrate to the business world the feasibility of motor transportation.

Atlanta - New York Tour Announced

PRACTICALLY identical with the rules for last year's run will be the regulations for the New York Herald-Atlanta Journal Good Roads tour, which will start on June 6 in Atlanta and finish June 14 in New York. Application for dates and sanction was formally granted and the entry lists will soon be submitted to the automobiling public.

The roads along the national highway, which were dedicated to the Good Roads tour last year, are reported in excellent shape, despite heavy rains. This proves the value of such preparation as was given prior to the run last Fall. It is planned during the next six weeks to put the whole route in the best of condition.

Interest in the tour is widespread in the South, and as soon as the preliminary arrangements have been completed, it is expected that the entry list will swell to large proportions.

A number of runs, all centering at Atlanta and tapping half a dozen Southern States, are being arranged as feeders for the trunk tour from Atlanta northward.

Officially the *Herald*-Atlanta *Journal* Tour of 1910 will be known as a contest of the "Fourth Grade," under classification A. This is the price class used in the 1909 tour, but for 1910 it includes seven divisions instead of six. The grades are as follows: $800 and under; $801 to $1.200; $1,201 to $1.600; $1,601 to $2,000; $2,001 to $3,000; $3,001 to $4,000, and $4,001 and upward.

This method of classifying cars serves to separate the lower priced machines, of which there are a very large number, making four divisions up to $2,000, as compared with $3,000 last year. It makes two divisions of cars between $1,201 and $2,000, instead of one division from $1,250 to $2,000, as required by the rules of 1909, thus equalizing the prize winning chances of many cars that heretofore were unduly handicapped. It will require a tour of the Good Roads type to fully demonstrate the value of the new classification, but the manufacturers are convinced that they have worked a big improvement.

Another change, and one that will be appreciated by the entrant who encounters trouble on the road or who lags behind through overconfidence, is that the rules this year allow three minutes before penalties begin at controls. Heretofore only two minutes have been allowed, and, while the added time is not great ordinarily, circumstances will undoubtedly make that extra minute look like a life saver in many towns this season.

POINTER FOR NOVICE DRIVERS

In a recent issue of *Harpers Weekly*, H. W. Perry writes some valuable pointers to the novice on the art of driving. Mr. Perry says that the beginner would do well if he took this advice: "Focus your gaze as far as you can see the road distinctly. The proficient driver learns early to watch the road far in advance of his car. On a straight, level road this may be several miles; on a winding road, only as far as the next turn; on a hilly road, the crest of the next hill; on a city street, as far as the condition of traffic permits the way to be seen clearly.

"By following this practice, small obstacles on the surface of the road may be seen long before they are reached, and, almost unconsciously, the machine is steered to avoid them.

"On the other hand, the novice or indifferent driver who concentrates much of his attention upon the road directly in front of his wheels does not see impediments far enough in advance to begin a gradual movement in avoidance of them, and is constantly in tight places on account of his lack of foresight. The difference in comfort to the passengers riding with a good driver and one who is not proficient is enough to prove of itself the soundness of this reasoning.

EMPLOYERS WANT TO BE SHOWN

Reliable chauffeurs are in sharp demand by private owners and taxicab companies, according to Charles A. Sibley, who conducts the Y. M. C. A. employment bureau for automobile drivers at 318 West Fifty-seventh street. Mr. Sibley says, however, that the employers are much stricter than they used to be with regard to qualifications.

Careful men who understand how to drive automobiles are at a big premium, but it is "bad going" for those who have blotched records, according to Mr. Sibley's observations.

LICENSED DEALERS ORGANIZE

Following the cue of other cities, Baltimore dealers who handle cars manufactured under the Selden patent formed an association known as the Licensed Automobile Dealers' Association, along similar lines to those laid down in New York, Philadelphia, Los Angeles, and other cities. There was a full attendance of the dealers at the Hotel Belvidere, April 20. Plans have been made whereby the members of the association intend to conduct their own show.

STATE TO INSTALL STONE CRUSHERS

MINNEAPOLIS, Apr. 25—Minnesota motorists, and especially those who use the country highways extensively for touring, found much comfort in the action taken by delegates to the State Roadmakers' convention. Much enthusiasm over the prospects for road betterment prevailed. Members pledged themselves to urge the State to install crushing plants in various parts of Minnesota for use in the work. A campaign was also inaugurated to urge a larger State appropriation for good roads, while plans for the expenditure of all State funds under supervision of the Highway Commission were mapped.

WILL MAKE AUTOMOBILE TRUCKS

ATLANTA, Apr. 25—Trucks capable of hauling from one-half to three tons will be built in this city in the near future, according to plans that have just been announced. The new vehicles will be called the McNeil truck and delivery wagons and they will be made by a company consisting of W. S. McNeil, W. S. McNeil, Jr., and J. McNeil.

It is planned to turn out the first of the trucks in two months. The weekly output will be not over five cars.

HILL CLIMB PROFITS FOR CHARITY

At a meeting of the South Bend Automobile Club, held in the Oliver Hotel last week, it was unanimously agreed that the club should co-operate with the city officials in the enforcement of traffic regulations.

It was agreed that the hill climb suggested by M. L. Williams of the 20th Century garage should be made a club event, and that all fees, entries and receipts be turned over to the Children's Aid Society.

AUTO PAYS FOR JERSEY'S HIGHWAYS

Figures compiled by J. B. R. Smith, State Motor Vehicle Inspector for New Jersey, show that during March the license fees paid into the treasury by automobile owners were about $52,000, or double what they were in March, 1909. Mr. Smith's conclusion, drawn from a digest of annual figures, is that the automobile pays more than sixty per cent. of the cost of road improvements in the whole State.

PLAN OUTING FOR ORPHANS

Between 3,000 and 4,000 orphans want to attend the festivities attending the annual automobile outing, which will be held this year at "Dreamland" Coney Island, June 2 ,but it is not certain that such a large crowd can be accommodated. Plans for transporting the children are being developed by the Automobile Day Committee of New York. The Women's Motoring Club will have charge of one section as usual and the New Jersey clubs have been invited to contribute cars and support. M. J. Budlong and William H. Haradon head the Car Committee.

NASHVILLE HAS AN AUTO CLUB

Nashville, Apr. 25—The Nashville Automobile Club was organized recently in this city and its birth was enthusiastically welcomed by many automobile owners. Despite the fact that this city is a motoring center, there has never been a club here until now.

Permanent organization will be essayed shortly and it is the intention to have the organization in full working shape when the Glidden tourists arrive on their trip South. Leland Hume was named temporary secretary of the club.

BUCKEYES TO TOUR HOOSIERDOM

Columbus, Ohio, Apr. 25—The Columbia Automobile Club has planned a reliability contest under the auspices of the club to be run to Indianapolis shortly before Decoration Day. The contest will be run at that time in order to permit autoists to attend the speed contests on the motor speedway at Indianapolis. The usual rules and regulations surrounding a reliability contest will govern the event. Already quite a number of the motorists of the Buckeye capital have signified their intention of participating in the contest.

WOMEN WORK FOR OILED ROADS

Women of Montpelier, Vt., representing the Woman's Club of that city have undertaken to influence public opinion so that a number of highways of the vicinity may be oiled. Last year an experiment was tried on about a mile of one of the roads just outside of town and the result was so favorable that the Woman's Club became interested. Montpelier is one of the favorite stopping places for cars en route from New York to the White Mountains.

RED CROSS SIGNS FOR DOCTORS

Baltimore, Apr. 25—Little signs, five inches square, containing a red cross on a white background, are being distributed to physicians owning motor cars by the Police Department of Baltimore, which give the medical men the privilege of speeding to calls without being held up by the police. These signs are to be placed on the left of the dashboard.

NATIONAL COMPILING RECORDS

The National Motor Vehicle Company of Indianapolis, Ind., has just from the press a leaflet giving a complete record of the winnings of the National car during the season of 1909. The information is concisely arranged, well printed, and should prove of much interest to autoists who follow this phase of the industry.

RUBBER TUBES ADVANCED IN PRICE

The Empire Tire Company of Trenton, N. J., has announced an advance of 30 per cent. in the prices of red automobile tubes and motorcycle tubes. The advance, according to the circular of the company, is due to the sharp rise in the rubber market.

Pathfinder Crossing a Bridge Near Corinth, Mass.

Woodland Trail Near Essery Springs

BETTER GOING FOUND IN ARKANSAS

After wallowing through the muck of Mississippi back to Memphis, the official pathfinder of the 1910 Glidden Tour crossed the Father of Waters, and at last reports was having an easier time of it on the journey to Dallas.

The Alabama, Tennessee and Mississippi bottoms proved a thorough test for the Chalmers "30" during this stage of the tour, and literally dozens of streams had to be forded that will be good roadways when the tour itself passes that way.

There has been little ease and recreation so far for the exploring party, because a strong shoulder and a sturdy arm have been far above par and have been in almost constant demand.

From Memphis the course of the tour extends sixty-two miles along the river to Trotter's Landing, where the official crossing will be made. This part of the course lies through an alluvial country, where negro residents outnumber whites, about ten to one. The dry weather that had been enjoyed for several days made this stretch a little easier than what had gone before, and reports from Arkansas that reached the party before crossing were that the roads on the western side of the big stream were in even better condition.

These reports proved to be well founded, for upon crossing, the party encountered fairly good going into Helena. The promises held out by the weather and the rising ground were made good in a large measure and satisfactory progress through Arkansas was achieved.

So far as it has proceeded, the pathfinding tour this year has been a record breaker in some respects. Some of the route has been over roads that could hardly be improved, but from the Kentucky-Tennessee State line almost into Memphis, the trip has been a terror. Unprecedented weather conditions which made anything that looked like a stream a raging torrent and covered hundreds of spots in the road with water that will be high and dry by June 1, worked to augment the labor of the pathfinders. Actual physical force and muscular endurance were required of everybody connected with the party and a great deftness in prying the car out of the soup-like mud was developed in all hands.

The streams and rivers of Tennessee, Alabama and Mississippi will long be remembered by the explorers for the problems in transportation that they propounded to the party.

Along the way, Scout Lewis has had many opportunities to do missionary work among the natives. Frequently when the crew was engaged in prying the pathfinder out of the mud, he would make impromptu addresses on the wide subject of good roads, his audience being residents of the locality who assembled quickly whenever the big car became stalled.

At Memphis the party was received with acclaim by the civic bodies and hospitably entertained by the Memphis Automobile Club. The worth of the Glidden Tour as a means of spreading the propaganda of good roads was the keynote of the addresses at the Business Men's Club and the mission of the automobile in carrying this message to the people was dwelt upon.

The road from Memphis to Helena was found to be of dirt and gravel for about one-third of its length and then came a long stretch of light clay. Active work with the split-log drag will make this part of the road an enjoyable stage. The Helena Business Men's League assisted the party materially in mapping this part of the tour and from Helena on to Dallas and from Dallas northward, all the way to Chicago, there will be official

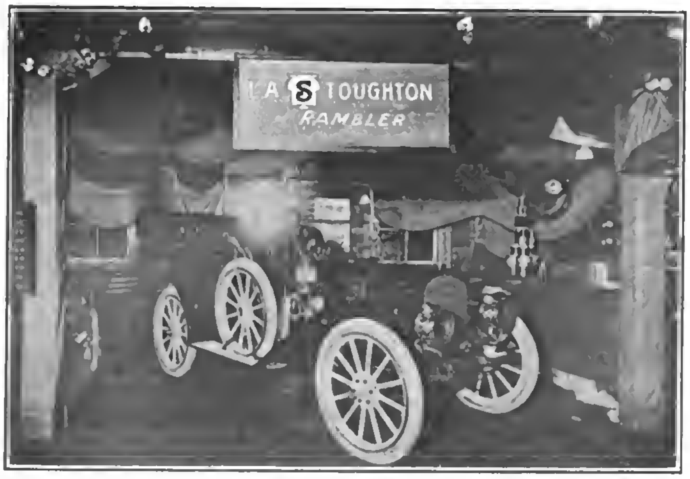
Interior of Bangor, Maine, Automobile Show

Stand Where Regal Cars Held Sway at Bangor Show



Rambler Exhibit at Maine's Premier Auto Show

RAIN FAILS TO SPOIL BANGOR SHOW

Despite rain and cold disagreeable weather during a large part of the week, the Bangor (Me.) Automobile Show scored a distinct success. Many cars were sold and hundreds of possible buyers were interested observers of the numerous exhibits ranged about the Auditorium. Society night, which was Wednesday, attracted a representative attendance, and the later sessions of the show, being more favored by the weather, made up in large measure for the disappointing "gate" of the opening nights.

The automobile parade, which was scheduled originally for Wednesday morning, had to be postponed, but when it took place, the delay did not serve to dampen interest in it.

PREPARE FOR 24-HOUR RACE

Extensive preparations, involving many improvements to the Brighton Beach race track, are being pushed along to make the track ready for the first 24-hour race of the year which is scheduled to take place May 13-14.

Besides numerous improvements in the runway of the track itself, a field stand is in course of construction and a stand for the chauffeurs is also being built. Improved score boards will be in place when the gates open and in a number of other instances details will be added to make the races more easily intelligible to the public.

The entry list has filled and the field will consist of twelve contestants. These are: Two Buicks, two Stearns, two Rainiers, Simplex, Houpt, Selden, Marion, Fiat and Renault.

The Motor Racing Association will conduct the affair.

CHARLES L. McINTOSH DEAD

Milwaukee, Wis., Apr. 20—Charles L. McIntosh, president of the Pierce Motor Company of Racine, treasurer of the J. I. Case Threshing Machine Company and a banker of influential connections of Racine, died early Tuesday morning at Naples, Italy. Mr. McIntosh was stricken on April 6. With Mrs. McIntosh and several friends he was on his return from a tour of the world, began last January. Mr. McIntosh was a native of New York. He was born sixty-three years ago and was for many years secretary of the Jewel Belting Company of Hartford, Conn. About a year ago he played an important part in the reorganization of the A. J. Pierce Motor Works at Racine, now the Pierce Motor Company.

FOUR JOIN ACCESSORY ORGANIZATION

The following named concerns were elected as members of the Motor and Accessory Manufacturers at the meeting of the board of directors:

Sherwin-Williams Company, Cleveland, Ohio, manufacturers of paints and varnishes.

E. B. Van Wagner Manufacturing Company, Union Building, Syracuse, manufacturers of die moulded, finished metal castings.

George A. Haws, 73-75 Pine street, New York, manufacturers of greases and oils.

Gasoline Motor Efficiency Company, 1 Exchange place, Jersey City, manufacturers of "The Homo" device.

SHARPLY OPPOSE CALLAN BILL

Sharp opposition to the Callan bill, now before the New York State Senate is being urged in some quarters of motordom. These objections are being centered against two clauses of the proposed law. The first is that it fails to provide a universal speed regulation. The second is that the clause applying to taxation is exorbitant in its terms. The law as passed by the lower house provides for a tax according to horsepower of from $5 to $25.

AGAIN SECURES ENGINE CONTRACT

The Falls Machine Company of Sheboygan, Wis., which some months ago received the contract for building all engines used in the "Warren-Detroit" by the Warren Motor Car Company, during the present season, has been favored with a renewal and will produce all 1911 engines for this concern. The 1910 contract called for 1,000 motors.

TRUCK-MAKERS SEEKING SITE

The Minneapolis Motor & Truck Company of Minneapolis, Minn., is negotiating with business men at Beaver Dam, Wis., a stove and foundry center, for the purchase of the cotton mill property and move its plant. The concern produces motor trucks from one to six tons capacity, listing at $1,000 to $4,000.

ALL READY FOR HARRISBURG RUN

With a strong entry list and every prospect of a number of eleventh-hour additions, the Motor Club of Harrisburg has every reason to be satisfied with the outlook for the three-day road contest that is scheduled to take place May 9, 10 and 11. Many well known makes of automobiles will contest and the route, which is through virgin territory in large part, has been selected to give the cars a thorough try-out.

The interest in the run is shown by the fact that four cities through which it passes have donated nine cups and trophies in addition to those given by the Wildwood Automobile Club, the Harrisburg Board of Trade and several others.

The route of the tour is through Lebanon, Reading, Pottstown, Norristown, Philadelphia, Hammonton, N. J., to Atlantic City.

Southern New Jersey will be pretty thoroughly covered during the second day of the run and Wildwood will be the night control. The third day's run will be back to Harrisburg where the cars will be turned over to the technical committee of which David Beecroft is chairman.

W. R. Douglas will act as referee. Four classes of touring cars and runabouts ranging in price from over $2,001 to under $1,601 and classified under the general provisions of the A. A. A. rules will compete. The event is the fourth annual contest of the Harrisburg Club.

RACE MEET INTERESTS MEMPHIS

Two events, scheduled for the near future have caused much interest to be aroused in the Memphis Automobile Club, and as a result of the increased activity of the members in club matters, there is a movement on foot to elect a salaried secretary to carry on the good roads work and to attend to the welfare of the club in other directions.

The two events referred to are the Glidden Tour and an automobile race meeting which is scheduled for May 21-22. The race meeting, which will be held on the Tristate Fair Grounds, has a program of events varying in distance from five to 100 miles with cash prizes for the winners. The manager of the affair is Homer C. George. The meet has official sanction.

U. S. MOTOR'S DETROIT COMMERCIAL PLANT

It is announced that the United States Motor Company will commence within two weeks, the building of a large commercial vehicle plant at Detroit. This factory will cost $700,000 and its plans consider a building of enough size to turn out 4,000 light delivery wagons during 1911. The main building will be 1,000 by 150 feet, and will be supplemented by several others, including a drop-forge plant, and a foundry.

The project will not interfere with the Alden-Sampson factory which will be operated as the heavy duty department of the commercial vehicle division, while the Detroit plant will manufacture light cars.

NEW COMPANY TO MAKE SPARK PLUGS

During the past week the Fry Manufacturing Company, recently incorporated by Walter L. Fry, Charles J. Kleber and others for $100,000, opened a new suite of offices at 1779 Broadway, corner of Fifty-seventh street. Mr. Fry is president and general manager, while Mr. Kleber will officiate in the capacity of secretary and treasurer. This newly organized company now has the exclusive sale of the Fry Spark Plug formerly marketed by the Standard Sales Company, which is now in liquidation.

ECONOMY TEST OF C. M. C. POSTPONED.

Rough roads have caused the postponement of the annual economy run of the Chicago Motor Club from April 28 to May 5. The run will be 200 miles to Lake Geneva and return. The route was reported so rough that an adequate fuel test was considered out of the question.

Beautiful Scenery Marked Part of Pathfinder Route

AROUND NEW JERSEY RELIABILITY RUN

One of the most interesting routes through New Jersey has been selected by the pathfinding party of the "Around New Jersey Reliability Contest" which takes place May 10 and 11. A Maxwell car picked out the route to be followed and on account of the extremely bad weather at the time that trip was made, the pathfinders experienced a trying time.

The run starts from Fifty-seventh street, New York, but the actual course commences at Jersey City. The route will be through Elizabeth, Rahway, New Brunswick, Red Bank, Point Pleasant, Lakewood, Port Republic, Oceanville, Pleasantville, to Atlantic City. The second day's run is via Pleasantville, Egg Harbor, Hammonton, New Brunswick to New York.

Present Status of Selden Patent Litigation

LITIGATION under the basic Selden patent has progressed rapidly recently. The present status of the matter is about as follows:

The original suits filed on behalf of the A. L. A. M. companies against seven unlicensed manufacturers in the Federal Court at Detroit have been supplemented by a similar action in that court against the Imperial Automobile Company of Jackson, Mich., and by suits against the Paterson Company of Flint and the Flint Wagon Works, both of which were commenced in the Northern Division of the Eastern District of Michigan.

Service was had upon each of the defendant companies and leave to plead was granted. The Columbia Motor Car Company and George B. Selden are plaintiffs of record in each suit.

Similar litigation was also commenced against the Parry Automobile Company of Indianapolis.

The complaints in all the suits allege that the defendant companies are infringing the patent, involving the principle of compression gasoline engines applied to the propulsion of carriages.

The defendants in Detroit and elsewhere announce that they will fight the cases to ultimate decisions and in a series of conferences tentative plans of action have been discussed. The Abbott Motor Company has taken a decided stand in the matter and several of the other defendants have gone over the situation with the Abbott Company's officers with a view to concerted action.

The Abbott Company gave out a statement a few days ago in which it was stated that the company does not believe in the validity of the Selden patent. The fact was alleged that while the matter had been in litigation for seven years, no final decision had been reached in the courts supporting the claims of the Selden advocates.

The suit of the Electric Vehicle Company et al. against the Ford Motor Car Company et al., which is pending before Judge Hough of the Federal Circuit Court of New York, progressed another step toward a final decision within the past week. The plaintiff prevailed at the hearing last fall and the present action is for the purpose of substituting the Columbia Motor Car Company as plaintiff in place of the Electric Vehicle Company, which it has succeeded.

A motion was made for leave to file a bill embodying such a substitution and after argument Judge Hough ruled in favor of the motion. The bill was accordingly filed and subsequent proceedings will follow in course.

In the meantime, the situation has been complicated to a certain extent by the filing of a suit against the various companies making up the A. L. A. M., on behalf of the Velie Motor Vehicle Company of Moline, Ill. This action was commenced in the Federal Circuit Court at Milwaukee and demands $500,000 as damages.

The bill of complaint sets up ten different causes of action or counts. The first of these alleges that the A. L. A. M. is an unlawful combination in restraint of trade within the purview of the Sherman act.

Second.—That the A. L. A. M. notified the plaintiff to enter the combination, demanding $17,000 and restricting the output of the company to 2,500 cars in 1910.

Third.—That when plaintiff declined to enter the combination, the defendants threatened to injure the business of plaintiff.

Fourth.—That the defendants conspired to prevent plaintiff from purchasing materials.

Fifth.—That they conspired to prevent proper advertising of plaintiff's output.

Sixth.—That the defendants through conspiracy prevented the Kopmeier Motor Company, agent of the plaintiff at Milwaukee from exhibiting the Velie car at the show in Milwaukee last winter.

Seventh.—That a New York advertising agency had informed the plaintiff that it could not handle the advertising of the Velie company because it would lose business of $75,000 a year by so doing.

Eighth.—That the A. L. A. M. in pursuance of the alleged conspiracy endeavored to prevent the extension of credits at banks.

Ninth.—That the defendants have conspired to prevent prospective purchasers from buying Velie cars.

Tenth.—That they have tried to get contract customers to break the terms of their contracts with plaintiff.

Service in this action has not yet been made upon the A. L. A. M., but it is expected shortly. Alfred Reeves, general manager of the association, returned Tuesday from the West. He made no statement with regard to defense.

Clark Enters Commercial Vehicle Field

WITH the reorganization of the Clark Power Wagon Company and the merger with it of the Ferguson Motor Company, the capitalization of the company has been increased from $50,000 to $500,000. The company will enter the commercial field with an adequate plant at Lansing, Mich. The men who compose the company are Frank G. Clark, president, who was the sole owner of the concern formerly known as Clark & Company. Mr. Clark became interested in the future of the commercial car some time ago and the present company is the result of his determination to go into the manufacturing of that type.

R. A. Radle, of Detroit, is treasurer of the new company. Mr. Radle is well grounded in the mechanical end of the business and has demonstrated much ability in selling. He is to be factory manager and in addition, he is connected with the Radle-Clark Sales Company of Detroit, which is closely allied with the Clark Power Wagon Company.

His history in the trade has been brilliant in both directions and much of the success of the Grabowsky Power Wagon Company, and the Rapid Motor Vehicle Company are credited in a measure to his efforts.

John Demmler, chief engineer, has been identified with the Packard Motor Car Company and was formerly connected with a number of European factories in important capacities.

B. H. Warner,, superintendent of machines for the Sheffield Car Works at Three Rivers, Mich., for several years, has been named vice-president and superintendent.

The car which will be turned out is a twenty horsepower, two-cylinder vehicle having a load capacity of 1000 pounds.

JOHN E. GEORGE, AUTO COMMISSIONER

BALTIMORE, Apr. 25—Governor Crothers has appointed John E. George, of Queen Anne's county, automobile commissioner, the position specified under the new Swann Motor Vehicle Law. He takes office the first Monday after May 1.

BRIDGEPORT HILL CLIMB IS DECLARED OFF

Owing to objections, raised by the city of Easton to the use of roads for such a purpose, the hill climb planned by the Automobile Club of Bridgeport, Conn., has been indefinitely postponed.

Court Ruling Upsets Second Offense Prosecution

EN an operator of an automobile is arrested for over-
peeding and is held for trial by the examining mag-
strate, he cannot be tried in the upper court in an
upon second or subsequent offenses, providing such
not alleged and investigated before the commit-
te.
tant ruling was laid down last Tuesday in the
eople of the State of New York against Walter
as prosecuted in the Court of Special Sessions
ffense of speeding.
ad in rendering the opinion of the court said:
was arrested and arraigned on a charge of
ting a motor vehicle at a speed of 25 miles an
ion 291, Chapter 30 of the laws of 1909. Three days afterward the District Attorney filed information against the defendant charging the crime of operating a motor vehicle at a greater speed than is allowed by law as a second offense.

"Counsel for the defendant moved to dismiss the action on the grounds that he had not been accorded a preliminary examination of the offense charged in the pleadings before the court. He contended that "second offense" was an aggravated misdemeanor under the statute and that the examining magistrate had not considered such a charge in holding him for trial.

"The defendant was not accorded his rights to examination before the magistrate as to whether he was the Walter Reppin who was once convicted for unlawfully operating an automobile. And in that respect a substantial right has been denied him. The case will be dismissed."

a plateau of magnificent alluvial land, west of the White river. Rice is the chief product and the largest rice mill in the world is at Stuttgart.

The roads are at present almost perfect, being the typical winding prairie highways on which the only speed limit is the car's power. The last 14 miles into Little Rock is over macadam pike, the like of which has not been seen since the pikes of Kentucky were left behind. The night entry into Little Rock spoiled the reception planned by the local automobile club, whose enthusiasm resembled that which has been general during the past three or four days and which is centered chiefly in good roads. A delegation from Hot Springs brought the best information and blue print maps to Dai Lewis immediately upon his arrival.

Little Rock has 65,000 inhabitants and in almost every block there are building operations under way. Very recently the coal resources of Arkansas have been made available for her own capital and a manufacturing boom is expected. Here, as in the rest of the State, one remarks the initiative and hustile that has come to be associated with the new West.

The pathfinder experienced a delightful time on the last leg of the Southern trip. The black wax of Northern Texas had no terrors for the party and reports of the course during the final 215 miles into Dallas, show the roads in fine condition. The car made forty miles an hour in favorable localities.

The Glidden Tour will make Omaha a night control. This decision was reached during the Eastern trip of S. M. Butler, chairman of the Contest Board of the A. A. A., en route home from California. When he reached Omaha, a delegation from the newly formed Nebraska State Automobile Association waited upon him and brought such pressure to bear that Mr. Butler decided to have the official tour extended across the Missouri river from Council Bluffs. Mr. Butler ordered the pathfinding party which is now in Texas, to map a route into Omaha. The change in the original plans will make the tour one day longer.

A. C. A. TO HEAR OLD MUSIC, MAY 3

A "Smoker Concert" at which Hans Kronold, 'Cellist, and a choir quartet will entertain the members and guests of the Automobile Club of America at the quarters of the club in Fifty-fourth street, New York, will be given May 3.

The occasion is one of the regular club nights of the organization, but special effort is being made to have the program considerably out of the ordinary course. The music to be given will all be of the ancient school. Refreshments will be served after the entertainment.

With the Agencies

Reception given to Ex-Vice-Prest. Fairbanks, at Indianapolis, on his return from around the world. Picture shows the Waverley electrics used to carry the ladies

C. S. Briggs, president and manager. K-R-I-T Motor Car Company, Detroit

A new depot at Newport, R. I., will be operated this season by the Foss-Hughes Company, which handles the Pierce-Arrow car in several big cities. The garage in connection with the depot will have facilities for handling 275 cars. Full lines of accessories and a complement of mechanicians, trained at the Pierce-Arrow factory, will be on hand.

During the past few weeks the Selden Motor Vehicle Co., of Rochester, N. Y., has appointed a number of new agents, among whom are the Gibbs Machinery Co., Columbia, S. C.; T. T. Maxfield, Bloomfield, N. J.; S. A. Whedon, Appleton, Wis.; Harrison Auto. Co., Birmingham, Ala.; Du Puy Motor Car Co., Houston, Texas, and E. B. Searle, Noank, Conn.

Renault Freres have opened a branch agency in Honolulu, H. I. The Van Hamm-Young Company (Limited) has secured the agency and will handle the new "American Special" 25-35, which is said to be well fitted to the exceedingly hilly country throughout the archipelago.

R. B. Edwards and H. D. Biggs, proprietors of the Broadway Garage & Sales Company, of Kansas City, Mo., have taken the agency of the Clark cars in adjacent territory. They will handle these cars exclusively.

The Brandt Motor Car Company, Cleveland, has taken the agency for the Acorn truck. The Acorn is a light delivery wagon. The Brandt Company is Cleveland distributor for the Kissel-Kar.

The Highland Garage Company, North Tarrytown, N. Y., has been granted the agency for the "Cole 30" by the Colt-Stratton Company, eastern distributors for the Cole Motor Car Company.

The Remy Electric Company, of Anderson, Indiana, manufacturers of the well-known Remy magneto, will open a branch distributing office in Boston, Mass., within the next two or three weeks.

Manager Harry Kortz, of the Euclid Automobile Company, Cleveland, has just opened agencies for the Atlas and Firestone-Columbus at Akron, Canton, Youngstown and Ashland.

After May 1 the location of the New York branch of the G & J Tire Company will be at 1924 Broadway. The branch at 10 West Sixtieth street will be discontinued.

The Apponaug Automobile Company, Apponaug, R. I., has taken on the agency of the "Cole 30" for Rhode Island. This agency was placed by the Colt-Stratton Company.

The Vail Motor Car Company, Northern Ohio distributors for the Clark and the Empire cars, have appointed agents in ten Ohio towns within a week.

The Smith & Rheineck Company, Rockwell avenue, has been appointed distributors of the White line for Cleveland and vicinity.

A. W. Lund, of River Falls, Wis., is a new agent for the Studebaker Automobile Company.

Cook and Carter, of Delaware, Ohio, have taken the agency for the Ford in Delaware County.

Personal Notes of Prominent People

George S. Patterson, who at different times has been sales manager for the Rambler, Reo and Premier cars, has been chosen general manager and director of sales by the Gaeth Automobile Company, of Cleveland. Paul Gaeth, president of the company, announces that the company will greatly increase the capacity of the Cleveland plant and manufacture over 500 cars during 1911.

M. Wertheimer has been taken into the Oxford Automobile Company, which handles the Brush car in Philadelphia, and with the addition to the company's personnel the company acquired the sales rights in the Quaker City and adjacent territory for the Inter-State car, the Muncie, Ind., product. The concern will still continue to do business at 518 North Broad street.

John D. Murphy, formerly with the Boston *Globe*, and the Maxwell-Briscoe Motor Company, advertising department, has accepted the position of advertising and publicity manager of the Selden Motor Vehicle Company, Rochester, N. Y. His many friends in the trade wish him success in the new venture.

John C. Perrin, superintendent and designer of the Lozier Motor Company will sail on April 28 for an extended trip through Europe. The Plattsburg works of the Lozier company will be in charge of Asst. Supt. Pollard during the absence of Mr. Perrin.

Gerald P. Hall, formerly identified with the sale of Midland Motor Company's product, has severed his connection with that concern to join the Pennsylvania Auto Motor Company, of Bryn Mawr, Pa., as general sales manager for the "Pennsylvania" company.

S. M. How, for two years with the Haynes Automobile Company, Kokomo, Ind., as special representative, has resigned to accept the management of the sales force of the Barger Automobile Company, of Cleveland.

Morris Grabowsky, for seven years secretary of the Rapid Motor Vehicle Company, has been appointed head of the commercial vehicle department of the United States Motor Company.

Marcus Allen has been appointed manager of the G and J Tire Company in New York. He will take charge of the new branch at 1924 Broadway as soon as it is opened.

Joseph H. Greenwald, Cleveland agent for the Marmon line, has leased larger quarters and will move to Euclid avenue and E. Sixty-fifth street.

Among the Garages

Maxwell four-cylinder car, of Sportsman type, in which R. M. Brown crossed the Alleghanies recently, being the first to make the trip this year

Morris Grabowsky, manager commercial vehicle division, U. S. Motor Company

The new garage of the Zell Motor Car Company, Baltimore, Md., is ready. Tapestry brick with tooled concrete columns and trimmings compose the front. The roof projects over the third floor line in front and its large, semicircular, green tile covering adds a live dash of color to the structure. On the first floor is the showroom, 50 feet square. At the rear of the room are mezzanine offices. In one of the corners of the showroom is a complete accessory department; directly underneath are stockrooms for carrying spare parts, supplies and tires. Storage facilities are provided on the entire second floor.

Motor garage opening is to be the central point of interest in automobile row in Minneapolis for the next two weeks. The Studebaker Brothers will be ready to move into their new building next week, as will also the management of the new electric garage, which will be the home of the Detroit Electric. The White garage is rapidly nearing completion, and the MacArthur-Zollars garage, at Thirteenth street and Nicollet avenue, is also about ready for a formal opening.

The Black Manufacturing Company of Chicago has sent M. E. Hoshaw to Elkhart as its personal representative in accepting completed cars from the Crow Company and attending to their disposition. He is to be manager of the traffic department and sales agent for that section. The Crow Company is turning out three to five cars per day.

As soon as the work of remodeling the building at 2337-2339 Michigan avenue, Chicago, is completed, the Federal Motor Car Company, recently incorporated to handle the Ideal electric car, will occupy the premises. This is expected to be about the first of June. The officers of the company are A. B. Carson, president, and J. L. Carson, secretary and treasurer.

The Powers Motor Car Company, Lawton, Okla., is erecting a two-story building with concrete floors and all modern improvements. The building fronts on E avenue, besides the 75-foot frontage opposite the postoffice. There will be an entrance driveway for motor cars to the north, south and east, giving easy access and egress.

Extensive alterations and additions to the garage of the Central Ohio Motor Car Company, at 61 East Spring street, Columbus, Ohio, have been completed. The office has been moved to the second floor giving more space for the showroom. An up-to-date repair shop has been installed and a large addition erected in the rear.

Southwork Brothers, Biddeford, Me., have just awarded the contract for the erection of a three-story garage of concrete. This will be located on Preble stret, between Oxford and Portland streets, will have a floor layout of 150 feet deep by 100 feet front, and will cost, it is said, $40,000.

George P. Lininger has opened a garage and repair shop in Greencastle, Pa. There are about twenty cars in the town, which is located on the old turnpike passing through Gettysburg, Waynesboro, Greencastle and Pittsburg, very well located to help cars over the direct route.

The new garage of E. S. Hessels at White Plains, N. Y., is approaching completion. The building is 50 by 125 feet, and is of brick and cement construction, about half of which is two stories high. It is expected that it will be ready for occupation about May 15.

In Ensley, Ala., the Morrison Motor Company, recently organized, will build on Avenue E, opposite the Elk's Home, a two-story garage of brick and concrete. John Morrison, a former lumber dealer, is president and financial head of the new concern.

The Studebaker repository at South Bend will be the headquarters for the E-M-F and Flanders cars in that city. The Studebaker Automobile Company has completed arrangements by which the cars will be sold from the repository.

A new garage with repair shop has been completed at Sixth and Walnut streets, Oklahoma City, Okla., by V. W. Shaler, to be known as the Standard Auto Garage. Mr. Shaler has the agency for the Standard Six and Halladay cars.

The Union Motor Car Co., 304-310 Central avenue, East Orange, N. J., has completed the erection of a large fireproof garage, immediately in the rear, in which a modern machine shop is being installed.

The McIntyre Automobile Company has moved into its new garage at 2203 Farnam street, Omaha, Neb. The garage is a commodious one, with all the modern appointments, the building being 25 by 128 feet.

A large fireproof garage, built at a cost of $25,000, will be leased by Harry Griffin and Chester Scott, Appleton, Wis. The garage will be 50 by 125 feet in dimensions, one story high, of solid brick and concrete.

Fred G. Hodges is building a $5,000 garage for the Foss-Hughes Motor Car Company at Wilmington, Del. A large stable is being remodeled for the purpose.

A. D. Foster has bought from Sherman & McConnell the brick garage occupied by the Electric Garage Co., at 2218 Farnum street, Omaha, Neb., for $40,000.

The State Garage is the name selected by the Auto Trading & Garage Company for its new headquarters at North avenue and Oak street, Baltimore.

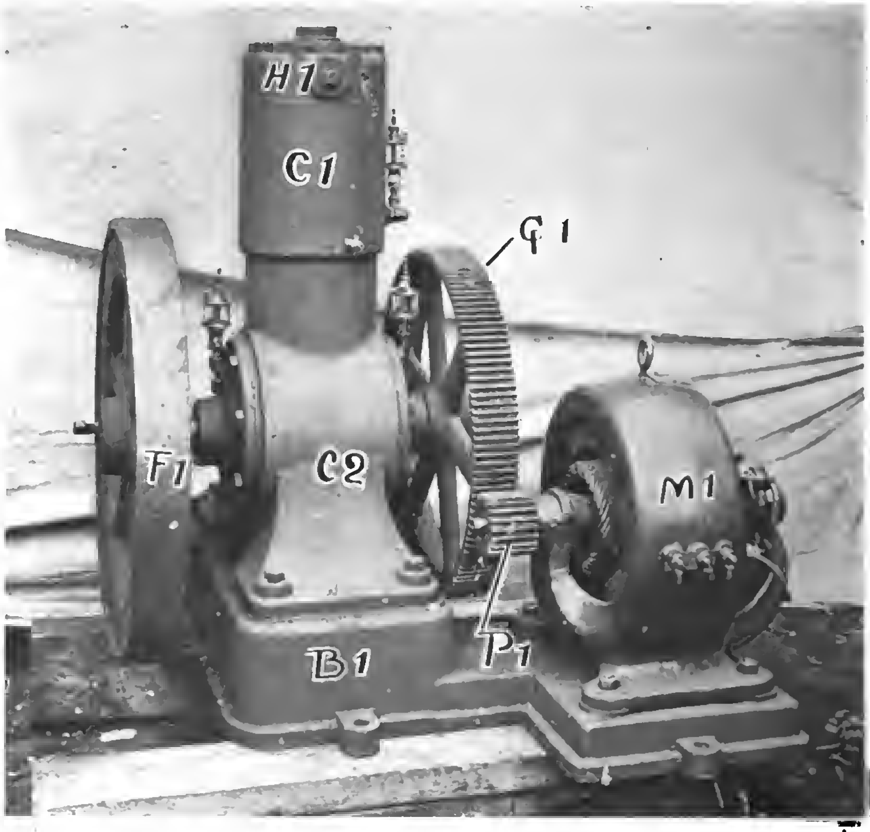
The North Shore Garage Company's new building, at Huntington, N. Y., is to be 50 by 225 feet, instead of 50 by 20, as first reported.

The Maxwell-Briscoe Motor Company, Indianapolis, Ind., is now located at its new three-story garage at Illinois and Vermont streets.

Charles Fenn will build a public garage at Antigo, Wis.

FAIRHURST AIR PUMP

The illustration here afforded is of the new Fairhurst Air Compressor as made by the American Air Compressor Works, 26 Cortlandt street, New York City, has been designed with a view to particular use in garages and plants wherein automobiles are made. It is intended to serve for any of the purposes to which compressed air is devoted, as in the inflation of tires, in connection with sandblast equipment, pneumatic riveting, etc. The compressor is of the single-cylinder, vertical type, with a separable head H1 securely bolted to the cylinder C1, the latter being integral with the crankcase C2, which is bolted to the sub-frame B1, the latter being extended out to take the electric motor M1, which furnished the power to drive.



Prominent Accessories

FIRESTONE DEMOUNTABLE RIM PRESENTS NEW FEATURES

One of the more recent improvements in demountable rims is the safety locking ring (in groove at extreme right of cut) that forms a part of the Firestone quick detachable rim with which Firestone demountable rims are equipped.

This locking ring is so shaped that it absolutely prevents the rim from coming apart and releasing the tire, no matter how severe the strain.

As illustrated herewith, the locking ring has a bearing not only on the under side of the clincher side-ring, but also on the outside edge of the base of the rim. It will be seen at a glance that the locking ring is held immovably and cannot possibly turn over in its grooves. The projection of the locking ring to an unusual height brings a strong support to the back of the clincher side-ring.

Firestone Rim With Locking Ring

The pins on the locking ring engage the slots in the clincher side-ring, forming a guide that ensures proper seating of the locking ring in its groove. They also prevent circumferential motion. In the quick detachable feature as well as in the demountable rim itself, the Firestone company regards safety as a prime requisite.

UTILITY IN GLOVES FOR THE WOMAN WHO DRIVES

Women are entering into the real pleasure of driving motor cars with added zest as the difficulties that formerly surrounded the sport are being removed.

In order to manipulate the steering wheel with comfort it is necessary to have the hands well protected and with that object in view the industry of making gloves for women drivers was instituted.

The Fried-Ostermann Company of Rockford, Ill., is marketing a full line of gloves of this description. They are said to be serviceable, well-appearing, daintily made and to embody all the latest practical improvements in glove-making of this character. The company announces that its catalog in colors, fully outlining the goods, may be had on application.

In the making of these gloves, the finest of leather is used, and the workmanship is also up to a fitting standard, much hand work being utilized.

New Style of Auto Glove for Women

Vol. XXII NEW YORK—THURSDAY, MAY 5, 1910—CHICAGO No. 18

THE AUTOMOBILE

Quaker City Third Annual Roadability Run

WITH the well-ordered precision of accurate machinery the Quaker City Motor Club conducted its third annual roadability run Saturday, from Philadelphia to Atlantic City, a distance of about 68 miles.

Scene at the Start, In Front of the Hotel Walton, Philadelphia
Where the Cars Finished In Front of the Strand, Atlantic City.
Above, at the Start, City Hall Beyond. Below, President Berger's Car

There was a snap and exactness about all the preliminaries and a certainty and vim in the run itself that savored of scrupulous care on the part of the officials.

It was a delightful affair, well handled, in which the maximum of pleasure and the minimum of discomfort were experienced. Under the conditions, speed was at a discount, the cup-winning cars being those that most closely approximated a secret time fixed in advance by Mayors John E. Reyburn, of Philadelphia, and Franklin P. Stoy, of Atlantic City.

This time was within the New Jersey speed limit and was decided upon by a unique process. Mayor Reyburn selected 3 hours 33 minutes as his time and Mayor Stoy fixed upon 3 hours 39 minutes and 19 seconds. These two times were added together and divided by two, the result being 3 hours 36 minutes and 9 1-2 seconds. The distance was approximately 68.2 miles, thus the running time required of the winner was only moderate, considering the magnificent highways included in the entire course.

The winners of the main prizes—for there were many, every finisher being awarded one—were all bunched within a short distance. It was merely a matter of guessing, as far as the operators of the cars were concerned, as any one of fifty entrants could have crossed the line at the exact moment of the secret time, if that moment had been known. As it was, scores of cars after completing the run were laid up alongside the curb on the near side of the finishing line while the owners waited until they thought the proper second had arrived to check in.

Winning Alco, Bitner Driving, at Atlantic City

In this regard a number of funny incidents occurred. One in particular resulted in woe for William J. Coghlan and his Chadwick car. Mr. Coghlan reached the finishing line at the Hotel Strand in 3 hours 36 minutes and 5 seconds. He could have gone on and checked in, but he had estimated the time at a little over 3.40 and he waited before taking the count.

The winner of the first prize turned up in the Alco entered by W. C. Longstretch. His time was 3.36.05, just 4 1-2 seconds less than the secret time.

Charles J. Swain's Winton was second, 2 3-5 seconds faster. B. F. Richardson's Mitchell and H. A. Rosenheim's Cadillac were tied for the third and fourth cups at 3.35.30, and F. J. Fanning's Thomas Flyer was fifth.

After the cup winners had been determined, the tedious job of awarding the approximation prizes was taken up. Every car that finished received some sort of an award and consequently much care was required in fixing the status of each entrant.

The twenty contestants that finished either just before or just after the cup winners were given humidors or fine clocks and each succeeding score of cars were given prizes of lesser value. The last car in was given a souvenir trophy of beauty and value.

Special factory prizes were awarded to the Stearns, Winton and Buick companies for the most numerous entries, classified on a basis of valuation. Each had five cars entered in the race.

There were 103 cars, including two electrics, entered for the run and of these eight did not start for one reason or another. All the rest finished except four. There were no accidents en route and the general comment after the finish was that the event was the most successful road run ever attempted under similar conditions.

Long before the hour designated for the start in front of the Hotel Walton the entered machines began to assemble. Philadelphia's most perfect downtown street was brilliant with bunting and color and life as the automobiles scurried about to find their stations.

These had all been marked off and numbered, and by noon Broad street was lined on both sides with panting motors. It seemed impossible to carry out the starting program without confusion of some sort, so great was the assemblage and so unwieldy seemed the mass of entries.

Two platoons of giant policemen in their best raiment had been assigned to preserve order, but they had little to do save to lend color to the beautiful picture and to give official character to the event by their presence.

In front of the Hotel Walton a specially synchronized clock, regulated from Washington, was the official timepiece. At the Hotel Strand, Atlantic City, the counterpart of the Philadelphia clock marked the seconds in unison with it. Exactly at 1 o'clock the word was given and car No. 1, Charles J. Swain's new Win-

Premier Entry at Atlantic City, Secretary's Car, and Packard Near Egg Harbor ton, crossed the line and sped along toward Market street, through a lane of interested spectators.

As Mr. Swain passed the timers he was handed a card bearing the time of his official start. Half a minute later, car No. 2, a White, entered by A. T. James, moved over the line and followed the leader. Down through the whole list this was continued. In a few cases the cars were not sent away on their official time, but wherever this occurred the official time was taken and in the final reckoning it was used as the basis upon which the time of the car was determined.

There was no attempt made at speed in the run to the ferry, because of the crowded condition of Market street, and the cars trundled aboard the big boats without special incident.

The day was all that the most enthusiastic automobile owner could have desired. The sun was warm and bright, dispelling the clouds of morning, and the rain of previous days had laid the dust so that ideal touring conditions were enjoyed. The roads through Jersey could hardly have been in better shape for the event and in the bright sunlight the procession of gaily decked automobiles, carrying laughing loads of passengers, added an element of life and power and energy to the scene that was wonderfully effective.

102	Stod.-Day. Wagon	W. Jackson	Non-contestant	

The route lay through Camden to Collingswood, Haddon Heights, Summerdale, Laurel Springs, Berlin, Waterford, Hammonton, Elkwood, Egg Harbor, May's Landing, Pleasantville to Atlantic City, a matter of 68.2 miles.

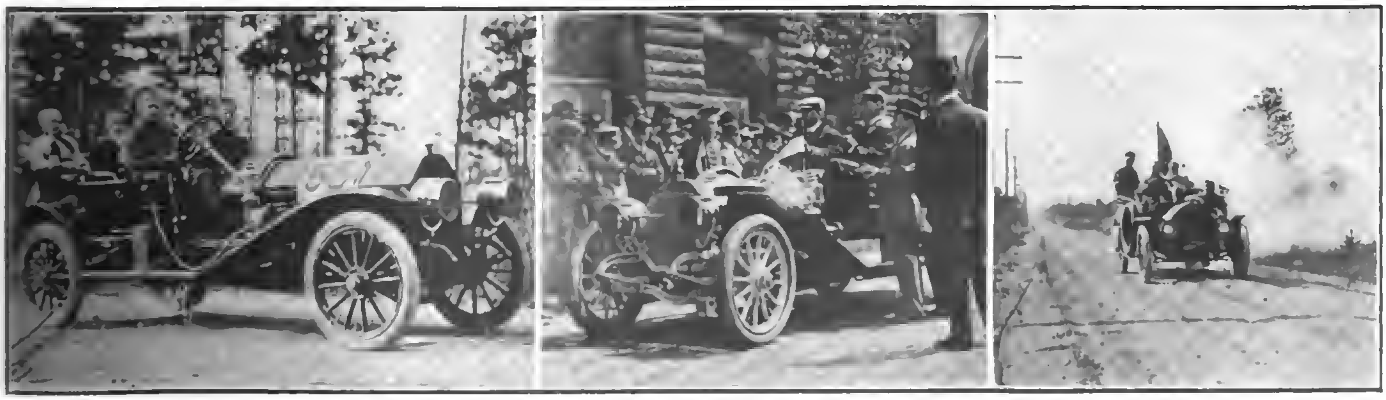
Conditions were excellent for speeding, but under the conditions framed by Secretary Harry C. Harbach and the contest committee, under R. E. Ross, speeding was useless and as a result the run developed into a nice, easy, genteel affair without mishaps and full of pleasure to participants.

These plans demonstrated their own wisdom more than once during the run.

The well-guarded "secret time" added just the element of uncertainty that was necessary to give everybody a good time.

The citizens of New Jersey exhibited intense interest in the affair. At every city, town, hamlet and cross roads, groups gathered and watched the flight of the cars. In most of these groups some person had a copy of the official booklet of the Quaker City Motor Club, containing the list of entrants, and as each car sped by heads would converge over the pages and when the car had been identified welcoming shouts and comments upon its position and speed greeted the ears of the tourists.

Approaching Atlantic City the participants got their first taste of salt air, for a cooling breeze from the ocean swept the great boulevard which swings out toward the point upon which the city is located. An express train moving at high speed toward Atlantic City gave the automobilists a passing temptation to show their best paces along this part of the route, but the participants did not take advantage of the opportunity afforded except in a few cases.



Big Six Chadwick, Locomobile at the Start, and Regal Plugger at Speed

Many of them arrived too soon, according to their idea of the "secret time," and for more than an hour the seaside resort was a riot of colorful cars that paced here and there awaiting the moment fixed by their owners to check in. As has been stated, some of these made fatal mistakes, but, on the other hand, the winners guessed right.

From the right side of the yard of the Hotel Strand a runway extends to the avenue, and when a car checked in it was run up this path, circled the yard and crossed the official line in front of the timer's stand in the porte cochere at the entrance to the hotel veranda.

As each car passed this line, the entrant handed in his signed timing card and the timers, under the direction of President Paul B. Huyette, of the Philadelphia Timers' and Scorers' Club, announced the second of the finish. This was noted upon the cards and the conditions were so well known by both officials and entrants that no chance for protest was given.

White Car in Q. C. M. C. Run Making Time

Pathfinder Crossing White River on Flat Bottomed Ferry Boat
Chalmers Pathfinder Near Little Rock, Showing Convicts at Work

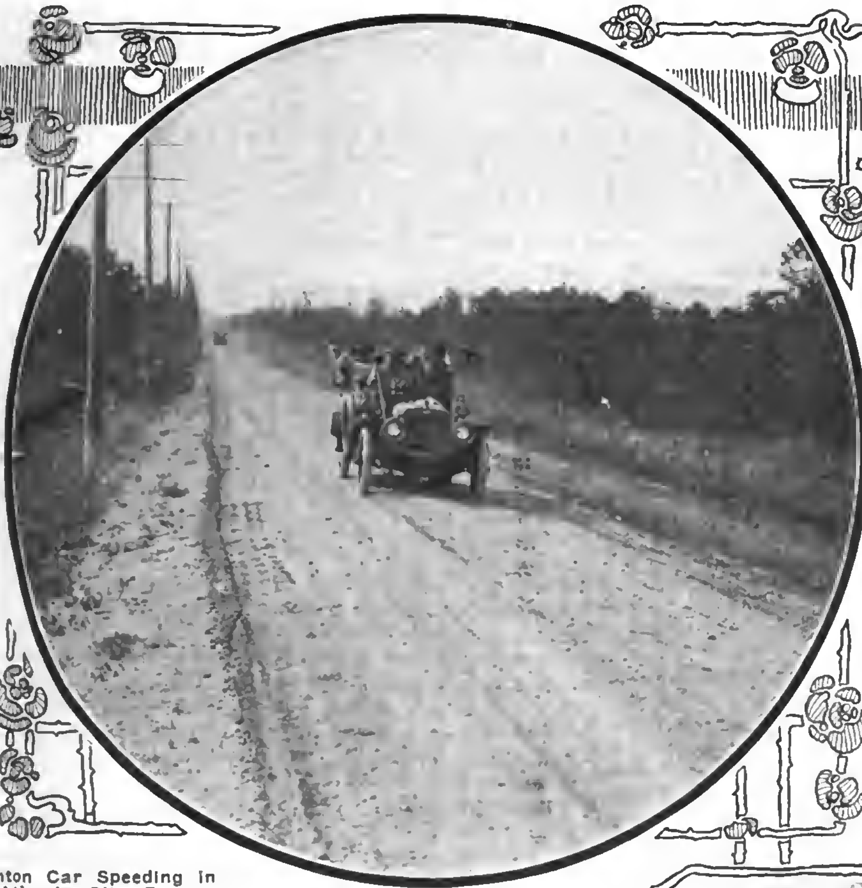
Glidden

Swinging northward at a rapid gait, the progress of the 1910 Glidden Pathfinder has been more than satisfactory during the past week. Road conditions have been superb. The weather one day was so hot that Driver Gardham was almost prostrated and was obliged to lay up for a full day's rest.

From Fort Worth to Oklahoma City the course lay over excellent going and northward from that place, the prairie roads extending into the foothills of the Wichita mountains, proved a treat to the explorers. At Lawton and Enid, and in fact, wherever there was a village along the route, enthusiastic welcome was extended.

It has been practically decided to make Wichita a Sunday stop of the tour. This conclusion was reached when it was found that Kansas City would prove too far to make by Sunday, as scheduled, if other points further South were to be covered.

Martin's Ranch, Texas, Apr. 29—The pathfinder crossed from the South into the West proper in its run from Dallas to Fort Worth Wednesday. Dallas has few marks of the cattle country about it, but Fort Worth proudly terms itself the "cultured cow town." The road hunters were entertained by the dealers' club of Fort Worth, and the *Star Telegram* and *Record* at a dinner in the Worth hotel, and found that men who have risen to fortune from



Winton Car Speeding in Atlantic City Run

The timers were equipped with a list of entrants in tabular form, containing the starting time of each car and as the announcement of the finish was made the time was noted opposite the car's number and in a few seconds the actual time of the contestant was figured out.

After all the cars were in, the cards and the tabulation were taken to one of the committee rooms of the hotel and in a very short time the result was ascertained.

Mayor Franklin P. Stoy and the contest committee had been called into session during the time this clerical work was being done and had given out the official figures of the time upon which the awards were to be based. Having determined the precise second, by averaging up Mayor Reyburn's time with that of the Atlantic City Mayor's, the timers selected the cars that had come close to the mark and within a little more than two hours after the last car was checked in the result was announced.

(*Continued on page* 860.)

Pathfinder

a cow puncher's saddle are now putting the same enthusiasm into motoring that they did into broncho breaking a decade or so ago.

Mayor William Davis, Col. Louis J. Wortham, general manager of the *Star Telegram*, Col. E. E Crowley, former secretary of the Cattle Raisers' Association of America and now president of the Dallas Dealers' Association, were all educated in the rough life of the plains and are all deeply interested in the development of motoring in this part of the country. Fort Worth has a population of 65,000 and 700 cars, mostly of the higher priced makes, are owned there. A million and a half was spent for motor cars in 1909.

The pathfinding car left Fort Worth Thursday following a pilot and spent Thursday night at Martin's Ranch, 29 miles north. Oklahoma City, via Terral, is the route for the next day's run.

Decatur, a town of 2,000, seat of Wise county, is the most important place between Fort Worth and Terral.

Pilots will escort the pathfinder into Oklahoma City. The roads through the stock country are, to a large degree, excellent, being of the resilient prairie type or macadam pike with exception of small stretches of cobble stone which would not total a mile between Fort Worth and Martin's Ranch.

Crossing Bridge Over Salene River, Out of Denton, Ark.
Pathfinder Met by Escort, Just Before Crossing White River

Owen Automobile and Methods of Production Involved

By THOS. J. FAY.

LATELY it has been the idea, considering the general situation, to advance along lines involving the popular conception and selling prices which agree with the average pocketbook. When the Owen Automobile Company, with its new plant at Detroit, Mich., decided to brave the 1910 market with a new-model, relatively high-priced, full-fledged automobile, the project took on divers important phases, and there was no gainsaying the fact that the quality of the car would have to be in full keeping with the financial situation, or the whole project would fall to the ground.

It will not be the purpose at this time to discuss car details, but the type of car and its main features will be found in the specifications given with this article. In order to show something of the extent to which the company has made preparation to build a pretentious automobile, an excursion will be made camera-wise through the plant, without forgetting that there should be a certain harmony of the manufacturing plan in the main; even so, close attention will be given to methods at random, rather than to follow out a systematic plan, it being the case that even were space available for a complete exposé, the story would become too heavy, and the great main situation would be lost in a mass of detail.

While the plant is less than half of the size which will obtain within a short time, the fact remains that the plant as it stands to-day is equipped throughout with absolutely new and modern machinery which was purchased especially for the manufacture of the new Owen car, so that the extensions which will be made when the new buildings are ready, will be of no especial interest from the point of view of this discussion, since they will be along the same lines, and will have interest in that the capacity of the plant will be increased, but the quality of the product will be that as reflected by the machinery equipment as it obtains at the present time.

Norton Milling Machine on Drilling Work

In a shop of this character devoted exclusively to the production of parts for automobiles of the highest character, large substantial and well-equipped universal milling machines serve an extremely important purpose. A of plate 1 shows a Hendy Norton Milling Machine, which, for the moment, is being used in a drilling operation, and the drill D1 is drilling a hole in the yoke Y1, which is blocked up on the platen P1.

Motors Are Assembled on Special Tilting Stands

In the assembling department, the idea of being able to get at every portion of the motor during the process of assembly counts in the long run, not only by way of saving time, but in the direction of quality of the finished product. B, plate 1, shows a cast frame F1 with sectors S1 and S2, which in turn support the motor arms A1, A2 at one end, and similar arms at the other end of the motor. By the means afforded, the motor is tilted so that the operator is enabled to examine the bottom B1 of the crankcase with the same facility that is afforded in the examination of the cylinders C1 when the motor is setting in the vertical plane. The motor, as it is shown in this example, is with the front end facing and the half-time gear train with the driving pinion P1, intermediate pinion P2 and camshaft gear P3 exposed to view, the cover of the half-time gearcase having been removed for the purpose. One pair of cylinders is mounted into place and the valve springs which are concentric with the valve stems are shown with a protecting cover C2 over them, there being one cover for each valve; this is a special feature used on this design of motor for the purpose of excluding dust or other foreign substances, and in order to assure a further degree of silence in the operation of the motor. One of the pistons P4 shows above the half-time gearcase, and since the bottom half B1 may be dropped down at will by the simple expedient of removing the holding bolts B2, of which there are a suitable number, it is to be seen that the connecting rods may be unbolted from the crankpins and let down so that it is not absolutely necessary to remove the cylinders from the crankcase in the process involved in the examination of the pistons, piston rings, or relating parts.

Gang Drill Utilized in Progressive Operations

When a gang drill is taken advantage of in connection with a series of jigging fixtures, one or more men may undertake to complete a given character of work, and speed as well as accuracy is thereby induced. C, plate 1, presents just such a drill, in which the spindles, S1, S2, S3, and S4, are mounted in the same plane, but the drills which they accommodate are not all within the same range. In this example, the spindle S1 will do relatively heavy work, S2 somewhat lighter, S3 falls lower in the scale, and S4 ranks as a sensitive drill. A combination such as this permits of a wide range of rapid work, and the accuracy phase of the situation is attended to through the use of jigs and drills or reamers, which are kept in good working order by tool makers in the tool room, thus eliminating the uncertainties which come if a plurality of workmen are permitted to follow the bent of their own inclination in the shop.

Radial Drills Serve Many Important Purposes

In the finishing of crankcases for motors and transmission gearcases, there are a considerable number of operations which may be done with precision and dispatch if suitable fixtures are utilized and radial drills are employed in the process. D, plate 1 presents a stout radial drill in connection with a fixture working on a motorcase, and a jig G1 guides the tool T1 into the work W1.

Straddle Mills Do Quick and Accurate Work

As an illustration of the utility mills E, plate 2 is offered, in which the work W1 is clamped to the platen P1 by means of the clamp C1, and the straddle mills S1 and S2 are utilized simultaneously in the facing off of the work. The distance between the straddle mills is fixed in view of the facing distance desired, and this idea has a wide application, provided the mill is sufficiently large and rigid to stand up under the increased rate of cutting.

Vertical Millers Handle Certain Work

Referring to F, plate 2, a vertical milling machine M1, with its spindle S1, has an end R1 engaged in routing out an aluminum half-time gear cover C1. In former times work of this character was done by means of vertical milling heads, which were attached to horizontal milling machines. For the lighter character of work this form of attachment served very well indeed, but the practice at the present time in the plants where automobiles are manufactured, demands far greater stability than is ordinarily obtained by means of an attachment of an auxiliary character.

Broaching Machine for Making Square Holes

One of the class of machine tools which was developed to a high stage in response to the demand of automobile makers was that which rendered it possible to broach square holes in gears as used in the transmission system. G, plate 2, shows a Lapointe broaching machine in operation, and the broaching tool, which does not show clearly, is actuated by the screw S1, which is of great power, which produces the square hole H1 in the gear G1 as shown. The capacity of this form of tool is so great that the old apathy to square hole work has entirely disappeared. This character of work is now done with substantially the same facility as obtains in connection with the drilling and reaming of a round hole.

Divers Automatic Machine Tool Equipments

It would be impossible to show even a reasonable few of the total number of splendid machine tool equipments employed in a plant such as the one of the subject. Many of the operations are completed on automatic machine tools, and the personal equation, which is so prone to interfere with the interchangeability of parts, is substantially done away with on the ground that the cutting tools, of whatever character they may be, are sharpened and sized by tool makers who are provided with every facility for the purpose, and a system of inspection in vogue renders it quite impossible for the artisans to make a mistake of sufficient magnitude to get by the work inspectors who take charge of the product from time to time as the occasion requires. Gear cutting is one of the classes of work which comes within the pale of the automatic system, and H, plate 2, shows one form of gear cutter which has a wide use in connection with the completing of sliding gears. The Fellow's shaper S1, with its reciprocating cutter C1, fashions the gear G1 by a progressive method of cutting, so that no one tooth is completed by a single cut; a series of cuts taken progressively one tooth after the other results ultimately in the completion of the cutting of the whole number of teeth, and the accuracy thus encompassed is beyond that rendered ordinarily possible, because the gear blank is cut at a constant temperature and the strains induced are but slight, so that distortions during the period of cutting are substantially eliminated.

Cylinder Design Indicates Engineering Skill

In view of the excellence of design of the cylinders, which is a matter of maximum importance in automobile work, it was deemed expedient to reproduce the working drawings and thereby more nearly portray the true situation, than will be possible in any other way. Referring to Fig. 1, (A) depicts the exterior of the twin cylinders on the valve chamber side, (B) is a plan in part section looking down upon the cylinders, (C) is a section through A A A A A, (D) is a section through B B, (E) is a section through one of the valves on the line B B, (F) is a section through D D and (G) is a section through C C C.

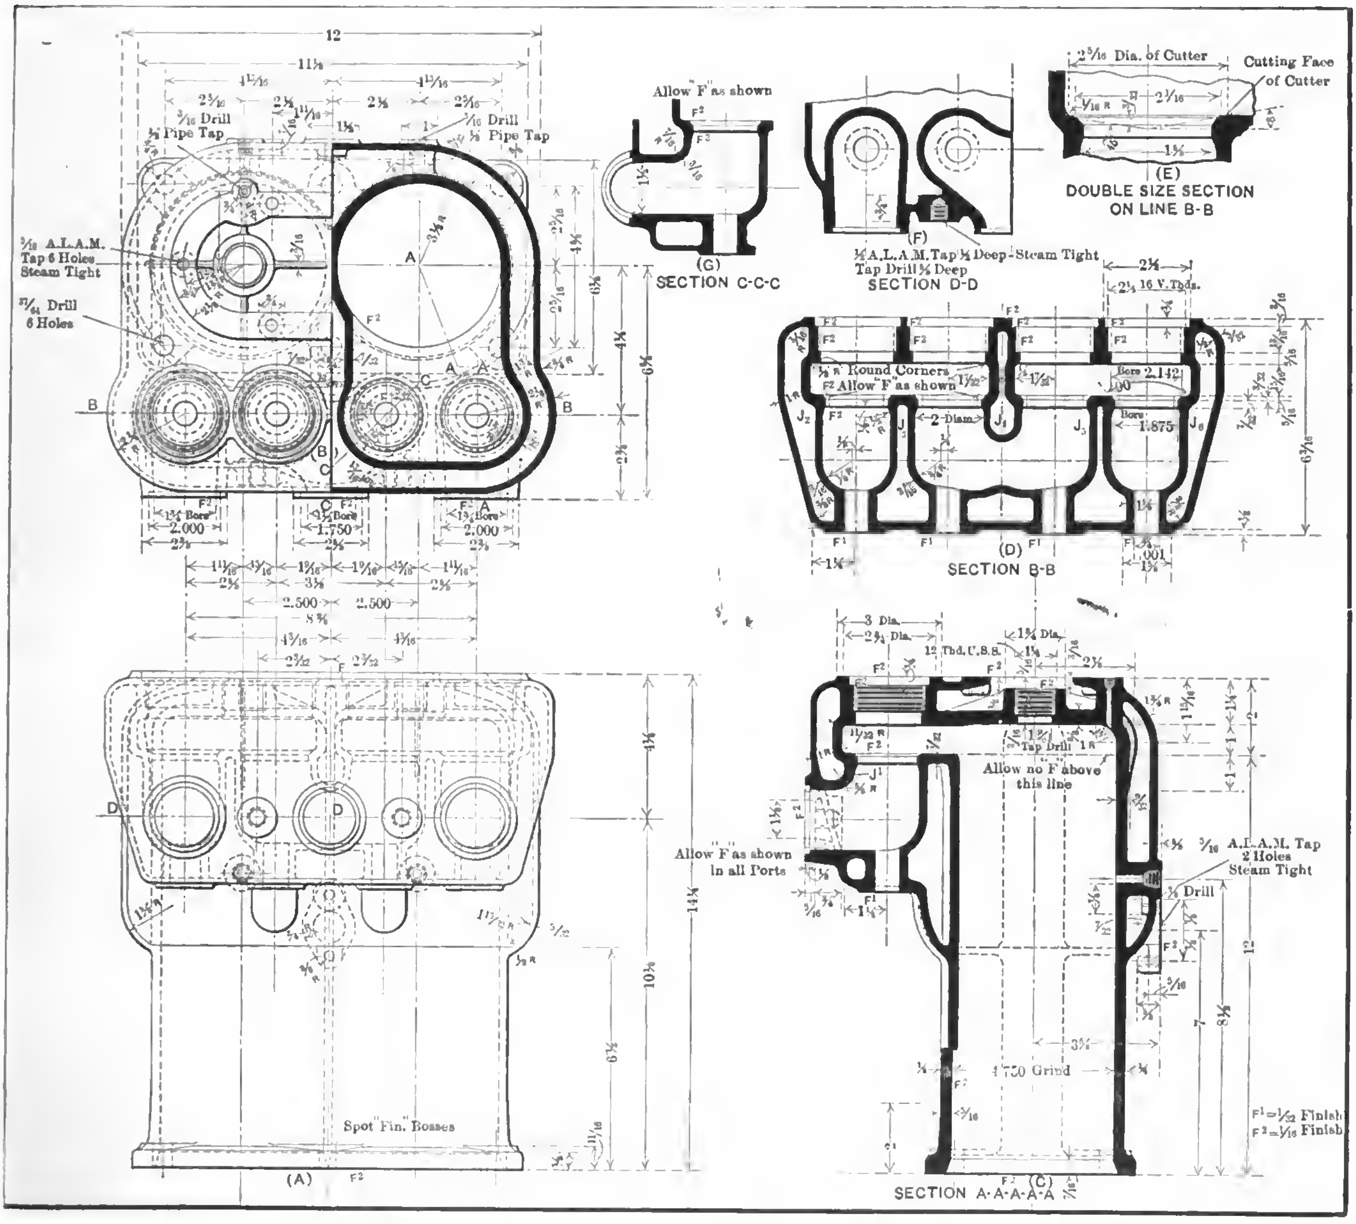


Fig. 1—Reproduced from working drawings of the cylinders of the Owen motor showing symmetry of design, uniformity of walls, and completely water-jacketed valve seats

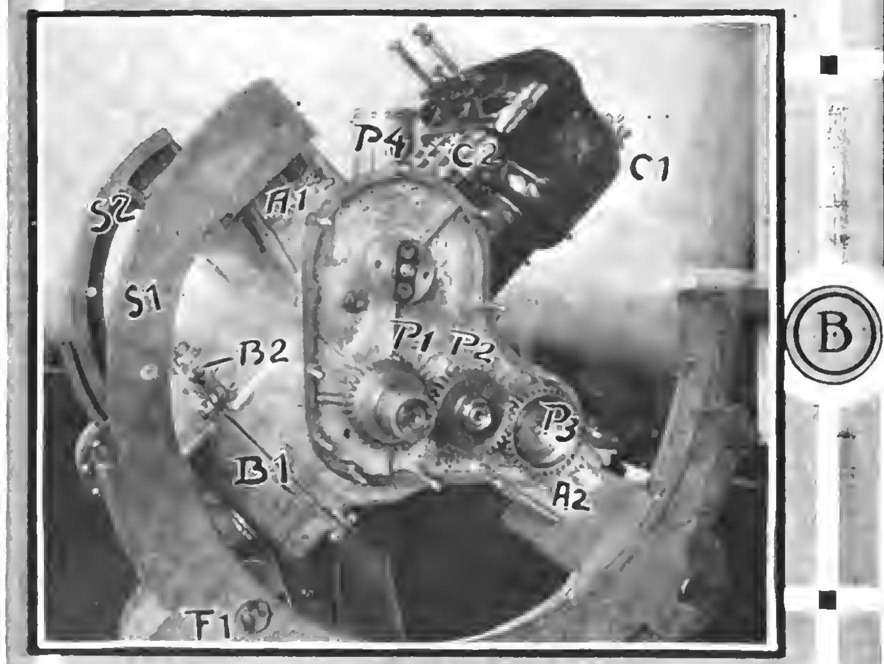
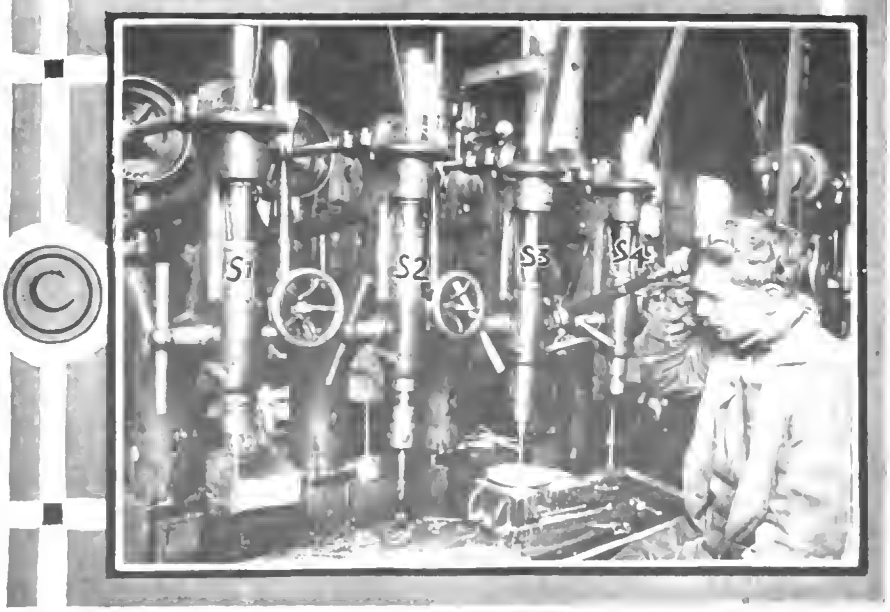
Referring to (C) Fig. 1, the cylinder walls are 1-4 inch thick in the main, but at a point approaching the flanging at the bottom the thickness is increased to 5-16 of an inch, beginning at a distance of 2 inches above the bottom line. In order that the

PLATE No I

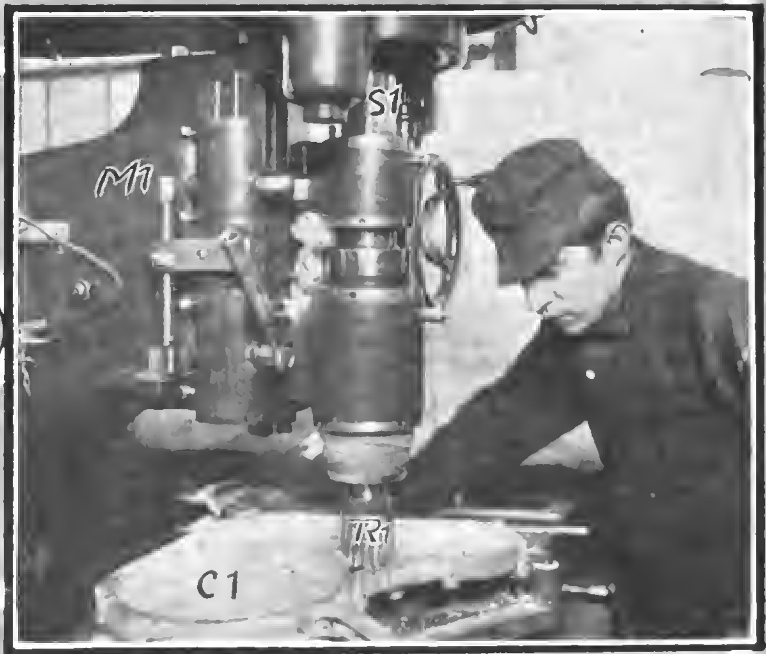




pistons may be inserted after the rings are slipped into their respective grooves thereon, the cylinders are beveled for a distance 7-16 of an inch up from the bottom, and the difference in diameter between the bore and the outer edge is greater than the distance represented by the expansion of the piston rings when the pistons are ready to insert. This detail represents the difference between success and failure, not necessarily when the car is being assembled by the skilled men in the shop, but later on in the hands of the chauffeur, who will destroy the piston rings in replacing cylinders if the beveled edges at the bottom of the bore are insufficiently designed.

The waterjackets are 3-16 of an inch in thickness, uniformly throughout, and the water sheet between the cylinder walls and the jackets is uniformly 3-4 of an inch, so that core difficulty in the foundry process is obviated. Care is exercised at every point to avoid the bunching of metal, and in this way the castings are rendered sound. Glancing at the valve seat, it will be observed that the wall at the point J1 passes downward for the better part of an inch before it intercepts the circular wall of the intake or exhaust. This is an important detail and the object in view is to maintain an even thickness of the metal around the seat of the valve, partly to assure soundness in the section of the metal, and again in order that the valve seat will be cooled at an equal rate all around its circumference. It has been found in prac-

PLATE No. II



tice that if the valve seats are only cooled for a part of the way around, the differences in temperature directly due to this inequality will produce an elliptical formation of the seat, and tightness will then be impossible.

Section E shows the valve seat detail, it being of the 45-degree beveled type, and above the valve the difference in diameter is increased enough so that the cutter which is used in fashioning the valve seat has ample clearance, and the metal on the top faces of the valves may be slicked down sufficiently to assure a perfect uniformity at all points in the diameter. Glancing at (D), which shows through the section B B, a further insight into the care with which the valve seats are water-jacketed will be given. J2, J3, J4, J5 and J6 are the points in the waterjacket adjacent to the valve seats at which trouble is wholly avoided, due to the provision of a uniform sheet of water around the exterior surface adjacent to the seats.

The valve stems are bushed, the idea being to maintain a certain tightness, and in the course of time as service shows effect the bushings may be replaced, if it is deemed expedient to do so. In order to assure a liberal heat transfer between the valve, its stem, the bushing, and the jacket walls to the water, the bushings are pressed in, and the character of the workmanship throughout is consistent with the objects sought.

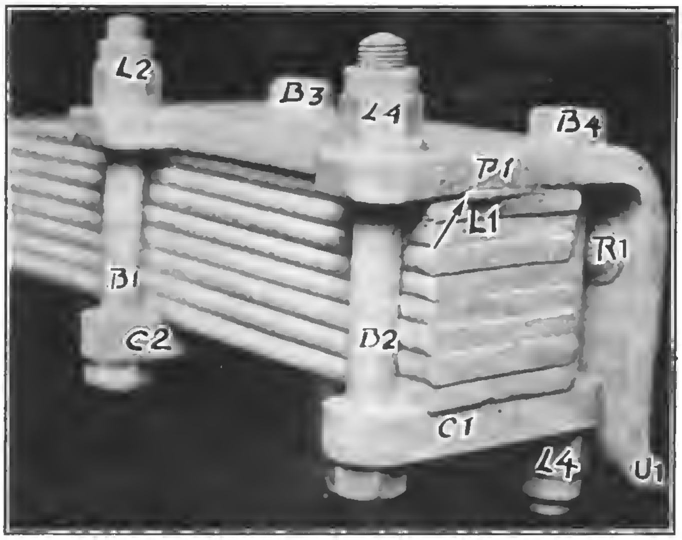


Fig. 2—Security fastening of the three-quarter elliptic spring suspension at the rear of the Owen automobile, utilizing a pressed steel bracket and locking methods

Glancing at the top of the cylinder in the view (C) the combustion chamber has an accommodation hole through which the core print passes, thus preventing the cores from shifting during the process of casting. This hole in each cylinder is threaded, and the plug which is threaded to match is provided with an overhang and a copper-faced gasket, so that when the plug is screwed home the copper-faced gasket is locked into place and tightness is assured.

There are divers other important features of design, which a closer study of the figures here presented will disclose, but the dimensions are all given, and beyond referring to the symmetry of the design and the general good appearance of the completed cylinders, the reader will be left to his own devices for the rest.

Conspicuous Design Features Throughout Chassis

The old idea of utilizing steel castings or malleable iron members in the construction of the chassis has lost favor on account of the uncertainties of castings. Fig. 2 shows how the three-quarter elliptical spring suspension is anchored to the frame and the pressed steel anchorage P1 is riveted R1 (of which there are a suitable number) to the chassis frame, but it also passes under the frame at the point U1, where it is also riveted to the flange of the frame. A cross-member at this point takes care of the stresses induced, and, as the illustration depicts, the metal is in sufficient presence in the pressed steel member to assure stability. The spring is held in place by clamping bolts B1, B2, B3 and B4, and pressure is induced between the pressed-steel member P1 and the cross-bars C1 and C2. There are eight flat plates in this portion of the spring; they are all of the same thickness and relatively wide. A measure of flexibility is induced by means of a thin strip of leather L1, which is placed between the top plate and the pressed-steel member P1. The whole system shows the earmarks of careful designing, and in view of the fact that springs will surely break if they are not tightly anchored, locking nuts L2, L3, L4 and L5 (the latter being hidden) are used in order that the clamping will remain tight in service, despite the tendency of nuts to back off.

Long Pistons Assure Tight Compression

Without attempting to cover all the points of merit, as they are presented in details of design, it will be considered enough to refer to one additional matter which supports the plan as a whole. The motor is of the long stroke type, and Fig. 3 shows the four pistons with the connecting rods and rings complete, in which P1, P2, P3 and P4 are the pistons, and the rings R1, there being three for each piston, are especially designed with a view to lightness, experience having shown that a light ring well designed will last longer and do better work than a wide and heavy ring. The joints J1 of the rings are cut on the bias. The connecting rods C1, C2, C3 and C4 are drop forged from a suitable grade of steel, are substantially of the H section, and are tapered so that the greatest strength in one plane comes at a point .6 of the whole distance up from the center of the large end at the crankpin. The caps C5 are held by four bolts, each

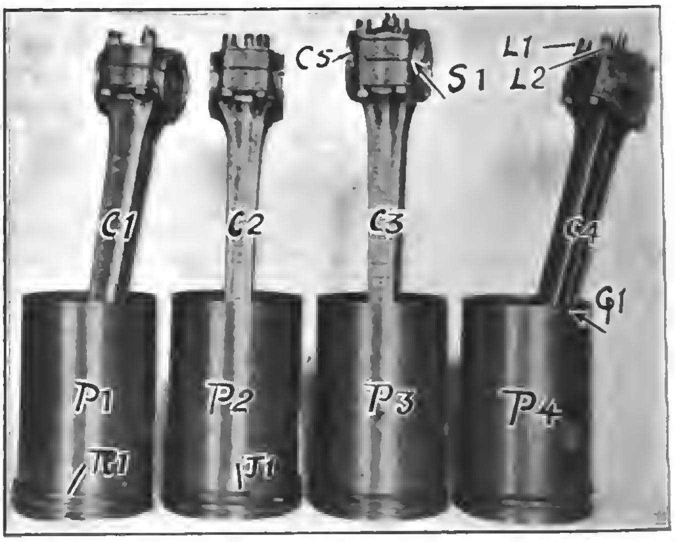

Fig. 3—The four piston units of the Owen motor showing an H-section connecting-rod system, long pistons, and relatively light packing rings

one of which is maintained in secure relation by locking nuts L1, L2, etc., and shims S1 are introduced for the purpose of permitting the autoist or his repairman to take up on the crankpin bearings, if in the course of time in service slack is induced. Perhaps the most important detail shown in this figure is the relatively great length of the pistons, not forgetting that an oil groove G1 is cut at the bottom of each of the pistons.

Specifications of the Owen Automobile

Type of body, six-passenger, fully enclosed.
Wheelbase, 120 inches.
Tread, 56 inches.
Tire equipment, 42 x 4-inch quick demountable.
Size of motor, 4 3-4 x 6 inches bore and stroke, respectively.
Motor rating, 60 horsepower.
Type of cylinders, L-head with inlet and exhaust valves on right side.
Crankshaft pins and bearings, 2 inches in diameter.
Crankshaft bearings, expanded Parsons white bronze.
Valve lifts, adjustable with rollers.
Water pump, centrifugal.
Ignition, high-tension magneto with coil and battery auxiliary.
Carbureter, float and nozzle type with auxiliary air valve.
Lubrication, splash system with pump for constant level and sump in crankcase.
Clutch, leather faced cone type with expanding springs.
Transmission gear, three speeds and reverse.
Transmission gear bearings, plain faced with Parsons white metal.
Transmission control, center line of car.
Driver's seat, left-hand side, making control right handed.
Front axle, drop forged special steel in one piece.
Rear axle, full floating type, with bevel differential.
Front springs, half elliptical, 2 1-4-inch wide plates, 40-inch span.
Rear springs, three-quarter elliptical, 2 1-4-inch wide plates, 50-inch span.
Emergency brakes, internal expanding emergency located on rear wheels, operated through beam equalizer and pedaled by right foot.
Service brakes, external contracting on drum on rear wheel, operated through beam equalizer and pedaled by left foot.
Steering gear, worm and babbitted nut with ball thrust through 18-inch steering wheel.
Location of steering wheel, left side of car.
Chassis frame, channel section steel with double drop, offset front and inserted wooden skids for transmission gear-set.
Half-time gears, helical type.

New Plant Where Selden Cars Are Built

By MORRIS A. HALL

FEW factories always interest, as showing just what "the other fellow" is doing in the way of buildings and equipment, but the new factory just occupied at Rochester, ., by the Selden Motor Vehicle Company, of which George lden is the president, carries an additional interest for the reason of Mr. Selden being connected with it.

be exact, the factory, which will be described in the folg pages, is not located right in the city of Rochester, being ighton, a suburb of that city, some two miles from the ss center. It is easily and quickly reached from the center city, however, by trolley lines which run within one block, by electric express running right past the plant, and omobile, through one of the most delightful of Rochesower-lined streets, and over excellent pavement.

factory is of brick, concrete, and wood, of what is techknown as slow-burning construction. The outer walls brick, the columns of concrete or 10 by 10 timber, in ases, with iron caps, while the floors present a novelty building line, being of two by eight timbers laid on edge, iled together sideways, while the floor surfaces, of sevenhard wood, are laid on top of this, being of matched The whole has all of the desirable qualities of a factory ing low in price, fairly good as a fire risk, easy and quick , simple and cheap to replace, strong to carry loads, and, not least, easy on the feet of the men.

ground floor has, however, concrete floors, while the fice entrance has tiled, and the offices ornamental hardoors. The master building, if so it might be called, is ries in height, and rectangular in section, being some long by 62 ft. wide. From the center of this projects ndary portion, this being another rectangle, closely apg a square, as to fingers, being 100 ft. long by 128 ft. rom this, again, there is a rectangular projecting part, r being the power house and heating plant. This is size, as compared with the other very long buildings, e for the purpose. In the location and planning of the ucture is to be found an example of the excellent pervading the whole layout. The factory has its own iding, and the upper end of this carries right past the use. The latter appears like any of the other buildthe outside, but, when entered, the floor level upon boilers and auxiliaries are placed is found to be lown much below the level of the other floors. At the reason for this is not apparent, but upon close it is seen to be for the purpose of reducing the of the fuels for the plant to a minimum. The end lroad siding carries up over the coal pit of the plant, orted in such a way as to leave plenty of open space. carload of coal, then, the car is run up, over the pit, d directly downward, without any handling.

coal lies upon the boiler room floor level, and the ndling it is reduced to the simple act of swinging it pit to boiler door. Since this entirely eliminates all imming, and similar work, considerable money is he operation of the plant. There are many other money-saving little economies in the plant.

to the buildings and their ground layout, another gular projection from the larger main building will the floor plans, given elsewhere in this article. This evator and stairs, and the rectangular building housentirely of brick and concrete, thus making that part ing wholly fireproof. This, combined with its isolahe other buildings, although in juxtaposition with the fire risk to employees and material very low. oo, other advantages in this planning which do not the first casual inspection of the plans.

he other two sides of a hollow square with the main buildings is a long, low, wooden structure, in which engines and cars are tested. This building, which will be scribed in more detail later, is but one story high, and is divi into three parts, one for engine testing, after the engines assembled in the cars, one for testing of the completed c and the third for experimental work and the construction special work. The whole building makes a home from wh the testers work out, the road testers making this their b from which to give all cars such a try-out as no purcha of the finished car will ever think of subjecting his prope to.

In the factory layout, the ground floor of the main build is occupied by the reception hall, timekeepers' offices, stairw to the second floor, dining room for the men, to be spoken later, storage for finished cars awaiting shipping order, ass bling of chassis as well as parts, stock room, testing and fi assembly room, shipping and receiving room, blacksmith sl and initial frame and axle assembly room, power house, testing rooms, as previously described.

Second floor arrangement is as follows: Front end, offic rooms, general offices and bookkeepers' rooms, drafting roo and chief engineer's offices, back of which are the rooms final assembling of bodies, fitting of dashboards, wiring electrical system, etc. Beyond this, going toward the back, the chassis painting room, and, at the extreme end of the flo varnishing and body painting room. This floor level shows a the skylights or saw-tooth roof of the one-story building.

This saw-tooth arrangement of the building of lower hei is resorted to in order to give as much light as possible, same effect being obtained in the larger, longer building throu the very large number of windows along the two sides of comparatively narrow building. The result, at any rate however it is obtained, is that of an unusually light facto Since plenty of light always makes for cleanliness, by mak dirt more prominent, this results in the whole plant be unusually clean. The final or ultimate result is to give a bet place for the men to work in, and, consequently, do better w and more of it. It is thus an asset to the firm, which thou doubtless carried some weight when the planning was done.

As to factory organization, the firm has one head and s eral associate heads, the whole working downward in a sort pyramid, from the man alone at the top, to the two hundred-c employees, the latter being a number which is constantly a mented as employees of the desirable class are obtainable. Geo B. Selden is president, and with the vice-president, Louis Fischer, of Buffalo, and the secretary-treasurer, John H. St man, cares for the larger problems of finance and administ tion. Robert H. Salmons is vice-president and general mana in direct charge of the factory. Working down from the m ager, under him are the departmental heads of smaller calib such as factory head or superintendent, sales manager, advert ing and publicity manager, purchasing agent, and chief engin in charge of all design, specification of materials, as well general outline of the processes to be used in fabricating parts. Below these, in turn, come the smaller departmen heads, in charge of restricted and specific parts of the wo as the various foremen, shipping and receiving clerk, bo keepers, timekeepers, foreman painter, stock clerk, head test assembling foreman, engineer, chief draftsman, etc.

With this form of organization, the course pursued from r materials and assembled parts, bought outside, up to the finis and painted automobile, ready for shipment, is about as follov The raw materials, in the form of bar stock, flat and round ir etc., bolts and nuts, assembled steering gears, radiators, m netos, coils, batteries, carbureters, wheels, tires, and simi parts come in by freight on the company's own siding. Af unloading directly into the shipping clerks' room they are

B

H

Selden Factory, Showing Electric Tracks

Second Floor Office View, Displaying Excellent Lighting and Plenty of Space

spected, and then go to the stock room, there to be drawn out for use as needed on departmental requisition. Both receiving department and stock rooms are on the ground floor and close to the assembling room, where the parts are to be used. This makes the travel of materials and parts about the plant as short and as quick as is possible.

In the panels on the previous pages, picture B of the first panel shows one corner of the shipping room, with its boxes and barrels of materials, coming in fast, for this company seem to have the railroad hypnotized to the extent of getting all of the freight cars needed for either ingoing materials or outgoing finished cars. At D of the same panel is seen the stock room, or at least a view of one corner of it. This stock room incorporates one very new feature in the tire room. The tire men have always asked for a dark, cool room, so when the factory was built a tire room was built to conform to these specifications. This is a basement proposition, being below the stock room, a vault specially built in for holding tires. It is reached through a trap door in the stock room floor, and has no windows.

In the same panel, picture A shows the chassis-assembling room, with a typical row of cars undergoing completion. The picture shows some 14 or 15 machines, but the exigencies of taking the picture were such as to preclude getting all those which were on the floor at that time, amounting to about 25. In a pinch, the floor space and arrangement are such that as high as 35 machines could be set up at one time. The picture also brings out one point not usually noted. This is the location of the gasoline tank on the chassis, under the front seat position, this being placed there at the start, and staying there throughout all of the strenuous testing of the car. In short, the gasoline tank is permanently affixed to the chassis at the start, the chassis then being tested with its own tank in place. In the usual case, this tank is carried on the body, and consequently is not attached until the body is put on, the testing being done with a special testing seat, carrying its own gasoline tank.

Picture C shows the blacksmith shop, where the assembling operations are commenced, the springs and axles being attached to the pressed steel frame, while the step and fender irons are also put on. The view shows clearly three or four frames being started, the one in the immediate foreground having the rear spring hangers in place, the front spring hangers, springs, and axle just being fastened. Also, the step and fender irons are in place.

At the lower right-hand corner is the assembling room for the chassis, another view being presented. This view reveals the tote boxes, in which materials, small parts, and all the little accessories needful to the men in assembling are carried around the shop. At the left a glimpse is had of a series of frames undergoing what might be called the second operation of assembling, this being the attachment of the secondary accessories, such as steering gears, etc. The view does not show it, but all frames after this second operation are mounted upon a special truck, designed for the work it has to do. This is a very neat, strong, serviceable little truck, and will be made the subject of future mention. In the main, it fits under the front and rear axles, interchangeably, and has four rollers, upon which the load may be wheeled around the shop, these being swivel mounted, so as to turn freely.

The second panel of pictures shows more features than corporate parts of the production processes. Picture F is the lunch room for employees, which the management has provided to enable the men to have a hot dinner without going out of the plant. While later plans may include the serving of such a meal at cost, the present situation is that the men employ someone from nearby to come in just before noon, bringing the noon meal, together with the necessary dishes and equipment. The photo gives small idea of the size of the room or of its clean, well-lighted appearance. The real size is such as to seat the whole factory force, with proper table space.

In addition to the dining room, the employees are well cared for elsewhere around the plant in other ways. On each floor, in every department, are provided a number of porcelain-lined wash stands for the men to wash up at, with both hot and cold water. Elsewhere, lockers are provided, while toilet rooms are many and well located. For the office force, the same arrangements, but upon a more generous and elaborate scale, are made.

Alongside of this, picture G shows a finished car placed in the box car which is to convey it to some happy purchaser. The wheels are blocked up and fastened in place, so as to hold the car firmly against the shifting and sudden starting and stopping which the freight car is sure to go through. This little matter th clearness the great care used throughout f the car to have everything come to the in perfect condition. Blocks, shaped to a fit, ie front and rear sides of the inflated tires, l with burlap. These are nailed fast to the o the second blocks, the purpose of which is om sliding sideways. Finally, the whole is ans of the longitudinals. H shows the cor- ssembling department in which the steering . adjusted, as well as the assembling of gear assembling and testing of reach rods, operat- r other of the important little parts.

e in, the small groups are assembled, then oom, after a very thorough test. This in- ccuracy of fits of shafts in bearings, side- or shake, tests for sufficiency of lubrication, shing of gears, for accurate fitting of keys any other similar little tests, all of which influence upon the character and worth of dy-to-use car.

:n, at I, the charging panel at which stor- irged, through the medium of the mercury : batteries, magneto, and other components and thorough telephone installation. This d by means of a series of signals, through bells, well distributed, by which any officer 'ocated in the shop and called to the office e.

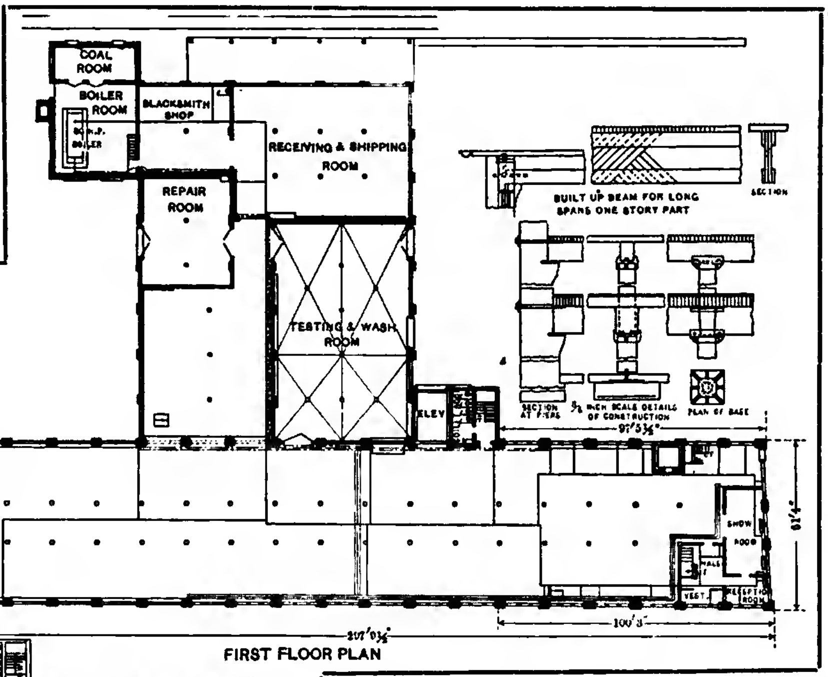
ant, electricity is used freely, the chassis- instance, having a lamp over the location ssis, or the space which each chassis would : shortage of good workmen keeps up so necessary to resort to extra shifts or night h the orders, the factory is well equipped ·k.

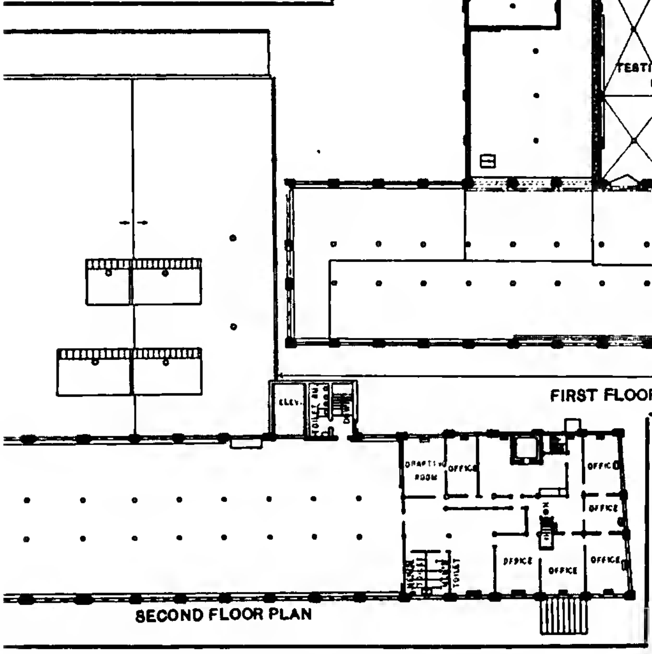
second floor, in the paint shop, to be spe- ssis are all being painted, and, does not bring it out, are in ;es of progression. The bird- left is the form upon which nnets of the cars are painted, Henry Selden's, a son of the rge over several of the larger ctory. On this and the pre- i views and plans of the new of which will be the subject of a future article, dealing specifically with the small details.

Testing taken as a whole, is very thorough, unusually so, and will be made the subject of later notice and comment. Not alone are the small parts tested during and after assembling, but the engines undergo a quadruple test, first the usual block test at the conclusion of the assembling process, and following the more usual run-in test. Second, the engine is tested after being put into the chassis, this being to make sure that everything is all right before going out on the road with it.

After that the wheels are put on, and when the chassis has been wholly assembled, the third or road test follows, this being unusually severe, both as to speed expected and as to hill-climbing ability. Next, the outside test having been completed, all the loose fits having been found and corrected, as well as all of the adjustments having been made, tested and proven, then corrected, the car goes to the paint shop, receiving its final dress, after which a body is placed upon it, and the latter is finished up, ready to go out. After all this has been done and the car is actually ready to ship, old wheels with still older tires are substituted for the new wheels with new tires, and the car gets its final test. This consists of two parts, one the outside road performance, and the other the dynamometer and stationary test. The two differ only in that in one the power is measured and in the other it is not. In these tests, the car is run into the testing shed, and the rear wheels run onto a pair of rollers, set into the floor, so as to project but an inch or so. There are a number of sets of these to take care of the large number of cars being turned out, namely, 600 for the current year, which figure will be raised to no less than double that, or 1,200 for 1911.

Of these a few have dynamometer attachment so that the power is measured, this being the actual power delivered to the road wheels, and not any formula or rating power. The others are just plain rollers, and the wheels just revolve idly, the idea being to test out the action of the engine and whole chassis, under actual working conditions. This test is one which brings out the sterling qualities of the radiator, and heat-dispensing system in a way that no other test could possibly do.





Floor Plans of New Selden Factory at Rochester

nd Floor Plan Showing Saw-tooth Roof.

In the appended floor plan, a sketch of some of the building details is also given, and will shed some light upon the construction of the buildings. This shows, for instance, the construction of the built-up long beams, which are made from two thicknesses of flat planks, cross-nailed and laid at angles.

The Magneto—Why It Makes Sparks

BY HERBERT L. TOWLE

A MAGNETO is in some respects a delicate piece of apparatus. It possesses many special characteristics which do not appear on the surface which can be learned by careful study, or as the result of ill-considered blundering. The best advice that can be given the owner of a magneto is to let it alone till he has both definite occasion to do otherwise and the necessary knowledge to act correctly. When a magneto does need something done to it besides the customary oiling and letting alone, the user's path is far easier if he understands the principle of the thing. To do so is not in reality very difficult, provided one starts with the elementary principles of electromagnetic induction. Most of the obscurity surrounding the subject is due to the fact that the average owner tries to skip the rudiments and begin at the top.

A magneto generates current in the same manner that a dynamo does, namely, by the motion of wires across the "field" between magnetic poles. To move these wires takes power roughly proportional to the electrical energy thereby produced; thus we say that mechanical is converted into electrical energy.

Precisely what is induction? It is the production of current in a wire (or other conductor) owing to changes in a magnetic field surrounding it. This magnetic field may be due to a magnet, or it may be due to an electric current flowing in another wire adjacent to the first, but not connected with it.

Take the familiar battery induction coil, Fig. 1. It has a primary winding of a few turns of coarse insulated wire through which the battery current flows. Surrounding the primary coil is the secondary coil, consisting of a large number of turns of small wire wholly insulated from the first coil. If the terminals of the secondary winding are brought close together as at *A*, and if the current flowing through the primary winding is suddenly broken, as by snapping the ends of two wires across each other at *B*, a momentary current is induced in the secondary winding. The potential of the induced current is higher than that of the battery current in rough proportion to the greater number of turns in the secondary winding, with the result that it is sufficient to jump the air gap at *A*. If the secondary winding had only the same turns as the primary winding, the potential of the induced would be that of the primary current.

A steady flow of current in the primary winding induces no current in the secondary. It is only the change of current that has inductive effect, and the more abrupt this change is the higher is the potential or voltage of the induced current. Current is induced on closing the primary circuit as well as on breaking it, but owing to electrical and magnetic lag it is not strong enough to make a spark at *A*. Lag occurs on breaking the primary circuit also, and to reduce it a condenser is used to absorb the extra current which would otherwise produce a spark at the point *B*. The condenser will be referred to later.

Instead of closing and opening the primary circuit, current may be induced in the secondary by moving one coil inside the other (see Fig. 2). If the primary coil be quickly inserted in or withdrawn from the secondary coil, a momentary current will flow in the latter when its terminals are joined. This current may be shown by connecting a voltmeter to the terminals.

The direction of the induced current follows a definite rule, as follows: When the primary current *diminishes*, the induced current takes the *same* direction as the primary current (see Fig. 1). When the primary current *increases* the induced current is *opposite* in direction.

The primary coil in Fig. 2 has no iron core. The action would be stronger if a core were inserted. The core and coil would then form an electromagnet, having all the magnetic properties of a magetized bar of steel, but in higher degree. A permanent magnet could be substituted for the electromagnet, and its motion into and out of the secondary coil would produce similar effects. In fact, the quick motion of either a permanent magnet or electromagnet anywhere in the neighborhood of the secondary coil will induce a momentary current in the latter, if its circuit be closed.

To explain the similar behavior of permanent magnets, electromagnets and coreless coils (known as solenoids), the theory has been broached that the molecules in every magnet, permanent or temporary, are themselves miniature magnets and that each has an electric current constantly circulating around it, see Fig. 3. In a permanent magnet, which is hardened steel, the molecules are more or less rigidly fixed. In the soft iron core of the electromagnet the molecules are plastic and assume a regular formation only under the influence of an electric current in the surrounding coil. When the current ceases, the molecules assume promiscuous positions like a heap of unmagnetized iron filings. This is only a theory, but it may help the reader to understand the relationship between magnets and electric coils.

Everyone has seen iron filings clinging to the poles of a magnet, and most readers of this article know that these filings group themselves in the direction of the magnetic lines of force

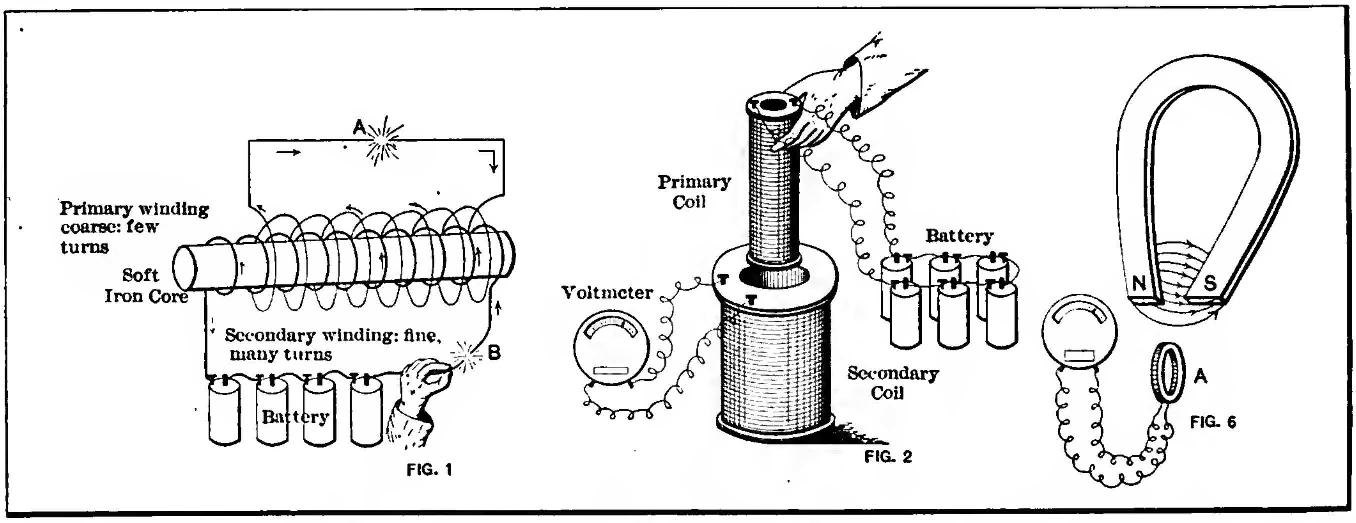


Fig. 1—Principle of ordinary battery induction coil, showing how current is induced in the outside winding by making or breaking a current in the inside or primary winding. Fig. 2—Showing how motion of an electric coil or magnet inside another coil induces a momentary current in the latter. Fig. 6—Lines of force of a horseshoe magnet, also showing how current may be induced in a coil. A, by moving it across the lines of force.

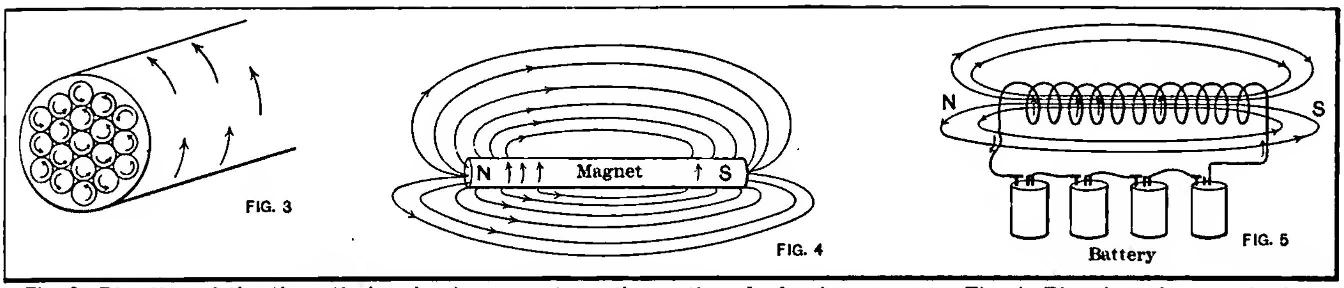

Fig. 3—Direction of the theoretical molecular currents at the north end of a bar magnet. Fig. 4—Direction of magnetic lines of force surrounding a bar magnet. The small arrows on the magnet itself show the direction of the molecular currents. Fig. 5—Showing that the direction of lines of force through and around a charged helix is the same as in Fig. 4.

which run from pole to pole of any magnet. Fig. 4 shows the directions of the lines of force about a straight bar magnet. If one were to take an empty helix, Fig. 5, and dust iron filings on the sheet of paper close to it, one would find that the filings would assume the same positions as in Fig. 4. In a word, the magnetic lines of force go through the magnet or helix, emerge from the north pole, and go into the south pole. They traverse iron much more readily than air. The smaller the air gap, therefore, the stronger will be the "field" produced by a magnet of given size. That is the reason why the poles of a horseshoe magnet, Fig. 6, are brought close together.

We are now in a position to see that what induces current in the secondary coil is in reality *a change in the strength of the magnetic field* as represented by the lines of force passing through the coil. In the experiment of Fig. 2 the lines of force are not as strong as they might be, because they must travel through the air outside the coil or magnet to return from one pole to the other. If we take a horseshoe magnet whose poles are close together, and move a flat coil *A*, Fig. 6, quickly between the poles, we shall get a stronger induction compared to the size of the magnet, because the magnetic field is stronger. This leads us to the action of the magneto with horseshoe magnets, Fig. 7.

In Fig. 7 the pole pieces are marked *N* and *S* for convenience, and a few imaginary molecules are shown dotted on the north pole to help the reader to remember the direction of rotation of the supposed molecular electric currents. This will assist in fixing the direction of the current in the single wire coil, which is supposed to be rotating on its own axis between the poles. The ends *a b* of the coil are supposed to be connected.

The theory of induction in a rotating coil is somewhat speculative. It will, however, be sufficient for our present purpose to state the behavior of the induced current and let the theory alone. This behavior is as follows: When the plane of the coil is vertical the flow of induced current reaches zero and changes direction. When the coil is horizontal the flow is a maximum. At intermediate points the induced potential is proportional to the rate at which the number of lines of force passing through the coil is *changing*. As the lines of force are horizontal it is obvious that for an instant, when the coil is vertical, a slight angular movement produces no change in the number of those passing through the coil. In that position, therefore, no current is induced. When the coil is horizontal the number of lines of force passing through it is momentarily *nil*, and the *rate* of increase or decrease in their number per degree of coil rotation is a maximum at that point. For intermediate angles this rate of change is proportional to the sines of the angles of the coil position; hence the theoretical curve of induced potential is what is known as the *sine curve*, Fig. 8.

As this diagram shows, the current fluctuates regularly above and below the line of zero current, which means that it reverses its direction at the zero point when the coil is vertical This action will be readily apparent if the reader traces carefully the motion of the single coil in Figs. 7 and 9. In Fig. 7 the coil is rotating counter-clockwise, and the lines of force passing through it are diminishing. Therefore the induced current will be in the same direction as the theoretical molecular currents indicated on the pole piece, i.e., from *a*, counter-clockwise following the arrows to *b*. In Fig. 9 the coil has got past the position of maximum current and the included lines of force are increasing. The flow is, therefore, opposite to the molecular currents; but meanwhile the coil itself has been reversed.

(To be continued.)

Best Means For Dustproofing the Highway

By MARIUS C. KRARUP

(Continued from last week.)

coal tar, can possibly become popularly accepted in practice, the solution of the dustless road problem offered by the investigating engineers and the construction companies must be declared to be academic, so far as the problem and the public are concerned, though it may be quite practical for the companies and for those communities which take advantage of it quickly. The good roads movement, while giving thanks for one solution, must insist that no solution be accepted as final whose general acceptance will pile economical hindrances in the way of its own practical application, and that therefore all other methods which promise results in the way of dustproofing the thoroughfares, even if these results are at present inferior, shall be followed up and improved until all of them combined furnish a variety of road engineering materials competing with each other and sufficient for the permanent and increasing needs of the public, both in quality and quantity. The situation created through the demand for dustless construction is a new one in the annals of road-building. Heretofore, though local scarcity of stone or sand or gravel and of any other one of the needed materials has been common, there has never been an absolute natural or industrial limit to the necessary supplies, and engineers have had a free hand in specifying one material or another as best adapted to a given purpose, with due regard to current prices and freight. With the dustproofing problem before them, the engineer and road builder must in the long run, as the case seems to stand at present, find himself greatly assisted in his task by the public's inclination to accept processes of low first cost, for the less important roads, in spite of mathematical proof of greater economy in a method requiring a higher initial investment. This inclination must greatly facilitate the experiments required for developing materials and methods capable of meeting the competition with coal tar and bitulithic construction, and eventually placing at the public's disposal an unlimited quantity of the raw materials from which the luxury of road comfort is to be distilled—unless indeed the aeroplane is to solve the problem in another way.

While the present article does not deal with the technic of dustproofing methods, but only with the means for facilitating their adoption, it seems impossible to pass without mention the most obvious chances for making the annual supply of coal tar keep pace with the increasing demand for dustless roads, until other materials of equal merit shall have been developed. It is admitted by the authorities on the subject of tests, that all experiments which have been conducted in this country with coal tar treatment of old macadam roads, have been crude and wasteful, none of the special labor-saving machinery having been used, which immediately was designed and built in France and England as soon as the dust problem became acute. By the use of this machinery the time required for completing the treatment of an old road has been enormously reduced, and the quantity of coal tar has been cut in halves at the same time as the quality of the work has been materially improved. Pneumatic spray nozzles have made it possible to dispense with the heating of the tar and to gain, besides, a greater penetration of the roadbed and a more complete filling of the interstices. But here the old method of heating and spreading by brooms has prevailed, while improved methods and economy with materials have been restricted to new construction conducted by private corporations, nowise interested in teaching economy to aldermen, road supervisors or the public in general. The use of the pneumatic nozzle has also led to experiments elsewhere—in France—intended to secure a greater compactness of the crushed stone bed, so that the tar would have less space to fill and would be lodged more securely, as well as binding the stones more securely, and it seems from recent reports that these new methods give improved results, besides greatly economizing on the coal tar or its substitutes. Apparently, certain possibilities are in sight for economizing on the dustproofing materials still further, as by experimenting with small, pentagon-faced, dodecahedron-shaped brick, which, if small enough, may be packed almost solid, and would require a very small quantity of tar for completely filling all interstices.

Even more farfetched experiments, as with corn husks or other vegetable fiber for arresting and holding dustproofing materials, especially those of lesser natural binding qualities than possessed by good refined coal tar, from being washed away by rain or penetrating to an unnecessary depth, would be in order under the condition of a threatened scarcity of materials which may at almost any time obtain. In England, the mixing of "creosote-oil" with resin or tallow proved of no lasting value, but experiments of a similar nature are conducted in many places, where dustless roads are much desired, while considerations of economy are imperative.

As in the rubber industry it has been found necessary and useful to experiment industriously with admixtures to the pure rubber, so does the dustless road problem portend an era of attempted admixtures with coal tar and other tars, some of which may eventually prove wholly suitable.

It is now believed to have been shown that the conclusions of engineers on the subject of dustproofing methods cannot alone be made the foundation for dustproofing projects and work. They are too uncompromising for the complex situation and by no means final. On the other hand, there is no other foundation for intelligent decisions. They represent, in extract, a full technical knowledge of all which has been done, and to this must be coupled an equal knowledge of local conditions and a goodly amount of sturdy business sense. Suitable steps for rendering all technical knowledge on the subject, so far as it goes, accessible and directly applicable to any given case, have never been taken. Some of it is recorded in libraries and periodicals, for those who have the time and patience to dig it out in each instance, from a hundred scattered and disconnected accounts, but the most recent, most valuable and most detailed portions of this knowledge are lodged in the minds of a considerable number of engineers, road builders and municipal officers, who cannot be brought together or otherwise consulted when a decision has to be reached. The first step in the desired direction must consist, it seems, in devising a form upon which the main and leading items of the provisionally established data may be entered in such juxtaposition that it may be shown at a glance where they are incomplete, and what relations each possible process for dustproofing bears to each possible condition of any road project which may come under consideration, the principal relations being those referring to comparative costs and comparative merits, including first cost, durability and degree of dustproofing. If maintenance cost is understood to mean the cost of a maintenance so thorough as to keep the road constantly as good as new, durability is included therein. The higher the maintenance cost, the less the durability.

Such a form, when complete, must be large and elaborate, considerably larger than any which may be practically shown on one page of this journal. A tabular outline for such a form is illustrated, however, in the framework schedule presented herewith, which may be expanded by addition and subdivision as much as necessary.

By extending the horizontal list it may take as many types of finished, old or new-built, roads, as fairly represent the varieties actually existing or which have a right to exist, some of which are dustproof, by virtue of their original construction: and pavements for cities and suburbs may be included.

By extending the vertical list, every method of dustproofing may be included which is applicable to one variety of finished road or another, only those methods being excluded which have already been shown unfit at any cost or plainly less economical for every variety of road than some other method which produces equal or better results. An emulsion, for example, which may have been shown to disappear from the road surface in a week and costs as much as one which lasts a month, has plainly no claim to entry. Water sprinkling as a means for abating dust would have no claim to entry, except for being so commonly used.

While a "Normal Road Schedule" of this kind would in itself be very useful at present if compiled on the best judgment of the most knowing, even though the work be done hastily, and while it seems advisable that the work should be done first in just such a rough and ready manner, but fairly complete in scope, its full utility could probably not be realized, until it were accompanied with a "Normal Road Book" giving definitions or explanations of the most approved method of construction for each variety of road listed on the "Schedule," with definite statements of the quantities and cost of each kind of materials and each kind of labor involved in the prescribed construction. That the cost would be an arbitrary, local or average cost, would not matter, so long as the quantities involved in each cost item were given, and no bewildering digressions were made to explain discrepancies which the individual road builder should be able to take care of without special directions. The exact methods for dustproofing each type of road should probably not be given in the "Book," but be left open to be decided by the development of the art at any given time, with the latest information incorporated in the "Schedule," subject to correction from time to time.

On the completed "Normal Road Schedule" the cost figures would be those based on costs of materials and labor as given in the "Book," and in any given instance of consulting the schedule, the figures would be modified in accordance with local prices and the specifications of quantities given in the book.

After the first rough work is done, a commission of experts, covering in their knowledge a wide diversity of conditions, may, of course, be necessary, in order to have the specifications of construction in the book as authoritative as possible, and each set of these specifications should be accompanied with a statement of the machinery required for the economical performance of the work. As there can be no object served in catering to uneconomical construction methods, but rather in encouraging the formation of local corporations which will be equipped to do the work in accordance with best practice, the commission should arrive at a definite conclusion on the exact methods considered preferable for each type of road; all leeway and concessions to local conditions being expressed in having both the schedule and the book embrace types of road and materials for their construction, which are not in themselves technically preferable. In other words, the variety of types should represent the variety of local conditions, but the figures of book and schedule should represent the height of technical insight in getting the best engineering results from available materials.

The accompanying sketch of a schedule has been filled with figures representing only the cursory surmises of the writer, based on an insufficient number of facts, but they will serve to illustrate how a complete and authoritative schedule may be used. For example, a municipality has a macadam road faced with hard limestone and desires to make it dustless. By following the vertical from B3, it is seen that several dustproofing methods are available, but that method V is most economical for trial, while method I gives more complete results, protecting against the dust from a long-frozen road as well as against that of the hot summer time, and is in the end also more economical. But, if the road were faced with soft limestone, the schedule would give a somewhat different answer. Showing a higher cost for the oiling method, it would raise the question of the reason for this difference, and inquiry would bring it out. In a comparison among methods II, IV and V, which come close together in cost for one full year, the decisive element might be that II and V require frequent treatments and the ownership of an outfit, while IV may be more readily done under contract and gives results for the whole year. In other cases, the results of comparisons are more surprising, and true and correct figures on the schedule would no doubt make them highly interesting.

The figures given under the tarring process in the accom-

Aeronautic Progress Along Constructive Lines

By MARIUS C. KRARUP

(*Continued from last week*)

weighty parts resting on the main structure, including passengers, forward or backward. An adjustment requiring final decision in the building of the machine consists in placing the tilt-rudder nearly in line with the forces of propulsion and momentum, and there seems to be an unsolved problem in the placing of a tilt-rudder where it will act substantially the same manner whether the propellers are in operation or have been stopped. With a motor suddenly stalled while the machine is going at high speed, a tendency to swinging the machine around the tilt-rudder is observed, when the center of gravity is much lower than the propeller shaft, the latter being in line with the sum of normal air resistance against propulsion, while the momentum of the machine acts through the center of gravity.

This consideration has been used as an argument in favor of the monoplane and rear tilt-control, on the ground that the single plane, with its relatively large horizontal extension, offers a greater resistance against the turning moment referred to than the two planes, of which the lower would be in the path of the upper.

Of greater actual interest is the function of the tilt-rudder for assisting in leaving the ground. Most biplanes built by amateurs show it to be a common impression that the tilt-rudder should be used for this purpose, for the tilt of the main planes, as the machine stands on the ground, is usually insufficient for lifting the machine at the relatively small speed at which it is desirable that it should be driven while in contact with solids and exposed to bumps against inequalities of the ground surface. The start of such a machine leads frequently to an abortive series of hops, while the machine whose planes are set at an angle such as ten degrees with the base line of wheels or skids, leaves the ground without any use of the tilt-rudder, as soon as a moderate speed is attained, saving the machine many shocks calling for a strength, as a ground vehicle, for which there is no further use after the machine gets into the air. On the testing grounds of aviators, machines of insufficient tilt are also seen rearing on their hind wheels when the tilt rudder is applied too early, and this does not only subject the structure to special strains, but immediately retards it by the increased resistance to propulsion at the abnormally high tilt of the planes, and the retardation causes it to fall down upon its front wheels again. The same action causes the short hops and bounds. The best construction calls for a high starting tilt and motor power sufficient to produce speed quickly in spite of the additional resistance caused by such high tilt.

A mechanical element in aeroplane construction which is seldom considered as coming within the scope of the designer, is suggested through the use of the term "aviator's luck." In the trying out of machines many have fallen from considerable heights, but relatively few have been seriously injured, and this has been ascribed to "aviator's luck." Something more is involved. The seat of the operator is usually so arranged that, in whatever position the machine falls through the air, a more or less frail framework is interposed between the aviator and the ground, and the breaking of this framework protects the man against the full violence of the impact. By suitable handholds and some calculation of the strength of the materials which are to break, as well as some consideration of their forms, so that the aviator shall not be likely to break bones against this material itself, the aviator's risk of mortal injury could, according to all physical laws, be still further reduced.

A consistent development of the aeroplane's natural qualities as a parachute, which have always been kept in view by designers, may also be depended upon to minimize the risks of aviation. It should not be possible for the machine to submit to the laws of gravitation without its large surfaces taking an approximately horizontal position, either automatically or by a very facile control movement. The tendency of the heaviest parts to seek the earth with maximum speed, leaving the parts exposed to relatively greater air resistance to trail behind, should be enlisted to forestall any edgewise or endwise precipitation of the machine, as has already been done in a newcomer among French biplanes. The advantage of the dihedral angle of some monoplanes, as an element tending to impart staunchness, has here been borrowed without accompanying it with a tail nullifying the safety gained.

According to testimony given in court proceedings, the method of steering a biplane of the Wright type consists now in first turning the outer wing to a higher tilt, so as to raise its level, and a moment thereafter turning it back to less than its former tilt and increasing the tilt of the inner wing, simultaneously with turning the vertical rudder inwardly, as a ship's rudder is turned. With other biplanes, the aviator considers it necessary in some cases to shut off the power, before he applies the steering apparatus.

The first method takes cognizance of the momentum of the machine. The other is intended to eliminate the surplus speed in which momentum finds expression. If the outer wing were not first given higher tilt, the first effect would be to cant the machine to the wrong side, because the momentum would raise the inner side despite the rudder action before the latter could cause any notable decrease in speed on that side; it being understood that an increase of tilt without increase of propulsion increases the lift and reduces the speed, but also that the momentum, being an accumulated force depending largely on the weight of the machine, is less influenced by a control-change than the lift, which is a constant, so long as the machine is held to a horizontal course. Much depends on the areas of the tiller and the twisted wing tips. It is especially when a sharp turn is wanted, and the speed of the machine is high, that the preliminary increase of tilt on the outside of the curve is desirable. It produces a course as in Fig. 1A, while Fig. 1B shows that a machine 40 feet wide along the front edge, in order to be turned around and take an opposite course within 60 feet of its previous course, must be managed so as to give the outer wing tip five times the speed of the inner wing tip. And to effect this change in relative speeds of different portions of the machine, in a very short time, is a matter which tries the balance of the machine severely at the present stage of aeroplane design.

With regard to the canting of the machine—inwardly as a bicycle—it is not quite so clear on second thought why it should be necessary, as it seems at first impression. The mind untrained in aviation usually freely assumes that such canting plays the same part in offsetting the centrifugal force, as it does in a bicycle. But that which happens so easily at a slippery turn of the road when a bicycle is canted in the usual way, shows at once that canting in the air, which is very much more slippery than any road. while it may serve equilibrium, does not do so for the usual reason, the latter applying only where ground contact and friction afford a fulcrum, against which the resultatnt of gravitation and centrifugality can spend its force.

The centrifugal energy acts horizontally through the center of gravity, and the resistance it must overcome in order to drive the machine out of its intended circular course, at a turn, is the air resistance against sideways motion. In a biplane, the center of gravity *c*, Fig. 2A, is usually slightly lower than the sum of these air resistances *r*, and the centrifugal force itself has therefore a tendency to produce canting. If the machine could easily turn around its axis, this tendency would be sure to take effect. but in such a turning movement it is impossible.

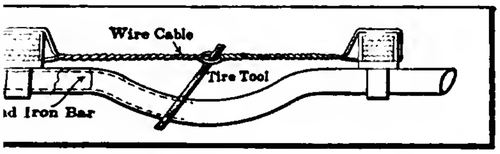
(*To be continued*)

Helpful Hints for Those Who Drive

EURS should seize every possible opportunity to rn about the mechanism of the car they are driving, learning to drive, and one way to do this is to gather ı be gathered from the unfortunate experience. By make roadside repairs expeditiously, and in such a to allow the car to limp home, the new driver soon ence in his own ability and this is reflected in his wheel. So, it is a wise plan to visit all the repair ›le, there to learn how repairs have been and are More than this, it is well to talk about these more experienced drivers.

y an amateur has had trouble with punctured floats rs, particularly with metal floats, for they are the at can be punctured. As a temporary method of unctured copper float, the use of sealing wax may cases where the float bas flooded, through the per- he solder, the first thing to be done is to bore a the float, in order to let out the accumulated liquid, ce should be carefully cleaned round the puncture. ıling wax should then be obtained, and a few drops lted over the hole, and should be pressed well r to fill it up. It will then be found that the float for any number of miles. One advantage of this the wax adds little weight to the float. It is ad- sten whatever is used for pressing in the melted to prevent its sticking.

give a new driver more trouble than a broken ly a broken front axle. If this be of the tubular river be fairly ingenious, a roadside repair may will allow of driving the car home, which is n. Thus, a case in which the tubular axle has to the spring chair, but inside of it may be ows: Obtain a piece of wire cable, or heavy ıay be used, or even in default of either of these rope. In any case, something which can be wo parts of the broken axle together. Attach gs, leaving lots of slack between them. Then roken end a piece of wood, which has been fit, or a round iron bar, or something similar ng driven this into one broken piece, drive the then keep them from separating by tightening r cable. This may be done by inserting any iece of iron, as for instant a tire iron, and

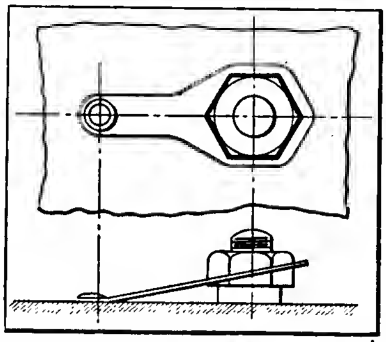


Repairing Broken Tubular Front Axle

hole is as tight as possible. Then, the tight- be so fixed in position as to render it im- ›me loose. It will then be possible to limp en axle, slow speed being a necessity.

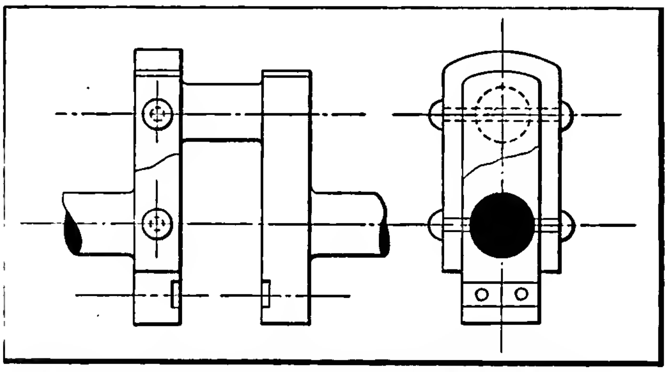
'e not a little attention whether in use or ater they will come into use, and then the manifest itself. One thing every automo- not to fiddle around with tbe wicks of his hould be left as they stand when the lamp ıe average motorist extinguishes his oil vn the wick, in order to save the clips of becoming slack by frequent usage. He d down till the lamp is next required, and vay to revolve the button, with the result that he frequently turns the wick right down into the oil reser- voir and has sooner or later to fish for it in the dark with a bent pin. Moral: If you extinguish a lamp by turning down the wick, turn it up again before you quit hold, so that you may never forget which way to revolve the button. The best way, however, to extinguish the lamp is to open the door and blow out the light, as that leaves the wick right for the next time of lighting.

One little subject which always gives trouble is the matter of nuts working loose, so that nut locks are a necessity. A simple form which every automobilist baving a hammer, cold chisel, some sheet steel, and a little patience can make for himself is that shown in the accompanying cut. A short piece of sheet steel is on a block of hard wood, and a hole punched through one end, this being a round hole to accommodate a screw or rivet. At the other end, the nut for which the lock is to be made is laid on the steel and its exterior shape scribed on the steel, using any sharp point, as the end of a file. This outline serves as a guide for the cold chisel which is brought into use to cut away the metal. The cut shows one which was made forming a full hole around the nut, but if the work is carefully done, this is just as ef- fective when tbe three sides only are done, the outer end being left open. When the end has been formed to fit the nut, one end is put in a vise, and the other end bent, to give the whole something of a spring. To use, the small end with the round hole is fastened down, by means of a rivet or screw, according to the kind of a job wanted, which, in turn will depend upon its location, and the party doing the work. This end being fastened down, the other will stand up at a slight angle. To screw the nut down, this must be held up above the top of the nut, out of the way, but as soon as the nut has been screwed home the lock can be dropped down over it, preventing it from backing off.



Simple Home-Made Nut Lock

Crankshafts will break at times, and the amateur should not start out with the idea that they will not, nor, more to the point, that they cannot be repaired. This particular repair is concerned with a shaft which breaks off in the cheeks or flat part. To re- pair, the nearest blacksmith makes a flat strop making it over one of the good parts of the shaft. Then with this flat strap over the broken parts, a couple of holes are drilled through and pins, bolts, or rivets put through.



Showing How a Crankshaft May Be Temporarily Fixed

Three-Point Suspension Explained

Editor The AUTOMOBILE:

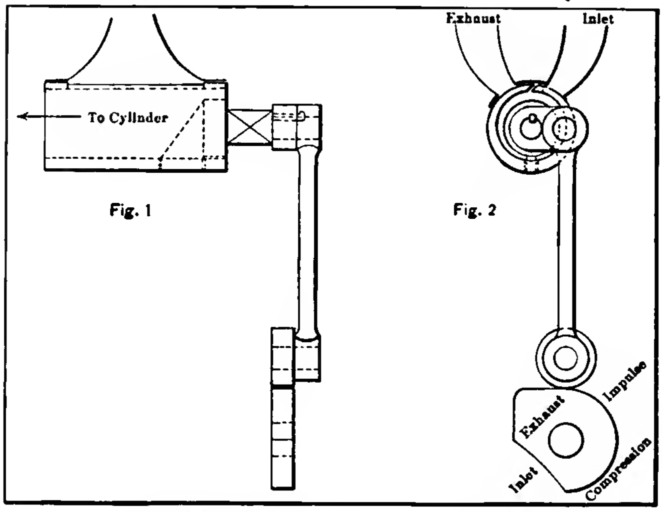
[2,248]—Will you please explain what is meant by a car being better because of a three-point suspension? I overheard the above statement relative to a certain car, and would like to know what it means. A CONSTANT READER.

Providence, R. I.

By three-point suspension is meant the hanging or fastening of some one or more parts of an automobile by three points only, instead of the more usual four, six, or more. In hanging an engine from three points for instance, this may be one in front and two at the rear end, or two in front and one at the rear. In actual practice, however, the former method is followed more often than the latter. The same, of course, applies to transmissions, and other parts as well as to engines.

The advantage of this form of suspension lies in the fact that at times one road wheel rises higher than the other by an appreciable amount, or sometimes both wheels on one side rise quite a little distance above those on the other side. This naturally twists and thus strains the chassis frame. The latter has, however, some slight freedom, but if the engine is rigidly bolted to a subframe by four or six points, when one side rises above the other, or when one side of the frame is twisted, the result is to twist the supporting arms of the engine. This may easily result in a breakage of the same. With the three point suspension, on the other hand, the single point is pivoted and the whole thing may turn on that point. This allows the plane of the two-point-supported-end to twist out of the former plane, but carrying the engine with it as a whole, and consequently doing no damage whatever. There are other supposed advantages of this form of suspension, but this is the principal one. In some form or another, nearly every manufacturer uses the three-point suspension.

That is to say, the three-point suspension for some one or more parts is used by many manufacturers, who do not make much of it in their advertising or other literature, but the fact remains that the suspension is a true three-point one, nevertheless. This would explain the apparently small number using it.



Drawing to Show Action of Irwin Type of Valve

Can't Find the Misfire

Editor The AUTOMOBILE:

[2,249]—I am repairing a Buick, Model F (1909) double cylinder opposed engine, and am having trouble with the rear cylinder missing fire. When it misses fire, the vibrator does not vibrate. I have changed spark plugs, but that does no good, the miss is about the same on high and low speeds. I have tried all kinds of adjustment of the vibrator, but nothing seems to do any good. Please give the cause of the misfiring and how to cure it through "Letters Interesting, Answered and Discussed." H. L. RICE.

Chilhowee, Mo.

There may be many causes for a misfire, among which may be the weakness of or stiffness of the vibrator spring on your coil. This is not usually counted in as one of the causes, but since you speak of the vibrators, we mention it. If the spring is too weak, the current will hold the vibrator down at all times, so that no spark will jump in that cylinder, while if the spring is too strong, the current will not be able to draw it down, with the result again, that no spark will occur. It would be well to try new and different vibrators, before experimenting with any thing else. The causes of missing are so many, and the things mentioned are so few, that it is hard to even estimate what the source of trouble may be. Broken wires, defective coil, loose wires at a binding post, worn out cells, water in the gasoline, spark out of time, water in the coil, and many other things may be the cause of the trouble.

Wants a Self-Starting Device

Editor The AUTOMOBILE:

[2,250]—Do you know of any one making an efficient self-starter for automobiles? I have a 50-horsepower 4-cylinder roadster of 5 3-8-inch bore and 5 1-2-inch stroke. Have just undergone an operation, as a result of which the doctor has forbidden me to crank a car for at least a year. If you can give me the address of any of the above parties, I will consider it a great favor. Expense of installation is no object if I can get what I want.

Stafford, Conn. CLAUDE PINNEY.

Self-starters have not progressed very far, and the best that can be done is to give the address of makers of devices for this work. Any one desiring a starting device can then write to these makers and obtain their estimate of the value of the various devices, as well as an estimate of the expense of attaching. Among those who make and sell a starting device, the following may be mentioned:

Auto Improvement Company, 302 Hudson street, New York City; Automatic Starter Company, 1512 Michigan avenue, Chicago; Gardner Engine Starter Company, Michigan avenue, Chicago; W. H. Herbert, 3312 Wabash avenue, Chicago; Monarch Motor Mfg. Co., 3145 N. Halstead street, Chicago; Starter Mfg. Co., Houseman Bldg., Grand Rapids, Mich.

Another New Type of Valve

Editor The AUTOMOBILE:

[2,251]—To the many interested in the development of the slide valve, and other substitutes for the poppet type of valve, the one shown in the accompanying figure may be of interest. In this, Fig. 1 shows a side view of the valve and its driving mechanism, while Fig. 2 is an end view. Both views show the relative ports in the valve chamber. No method of connecting a returning spring or dash pot is shown, but something of this sort is a necessity. The bore of the valve opens into header or passageway leading to the cylinders. The exhaust is delivered directly into the exhaust pipe, and the charge is taken directly from the inlet passage so no auxiliary valves are required.

Bradford, Pa. G. W. IRWIN.

The design appears to have much merit, and to be worthy of some further study. Thus, if the cam arrangement were used, a guide of some sort would have to be used, else the cam would throw the arm to one side at the first rising of the exhaust part, the device then being inoperable. Granting a guide, and a spring or dash pot for the return, the device might not be so simple as it seems in the sketch. The idea, however, of a narrow though very long opening into a large diameter circular passage communicating with the combustion chamber, is a very good one.

More About Bissell Helicopter

Editor THE AUTOMOBILE:

[2,252]—In your issue of March 3, I notice a letter from J. U. Baker which is in criticism of my "flyer." Why, if the propeller cannot work well as shown, can't the rim be made of some light material, such as wood or aluminum? A wood pulley 18 inches in diameter will not burst at over 4,000 r. p. m., and then, if the engine is geared (like some of the French engines are made) to run at say 1,200 revolutions for 400 of the helicopter, it seems to me the desired result can be obtained. To overcome the torque he speaks of, it is only necessary to turn the steering handle to th right or left according to prevailing conditions. The whole business with man and 10 gallons of gasoline would not weigh over 450 pounds, and they guarantee a six-foot, two-blade propeller at the above rate of speed to pull 200 pounds, so I should think at a rough guess the above figures are approximately correct. JOS. E. BISSELL.

Pittsburgh.

Unfortunately, it is impossible to have light weight and flywheel capacity at one and the same time, so if the device depends upon the flywheel ability of the rotating weight, as incorporated in the rim of the so-called gyroscope, it will be impossible to have light weight, that is, for the purpose, the materials mentioned cannot be used. As far as the figures given are concerned, it is impossible to verify any such figure as given, namely 4,000 r. p. m. for an 18-inch diameter wheel. This would give a surface speed of 18,840 feet per minute, which is far beyond the ability of glued wood (as all wood pulleys are made up) to withstand. Kent gives the following formula for the strain per square inch of sectional area in flywheels of wood:

$$S_1 = .00000225\ V^2$$

in which S_1 is the strain per square inch of sectional area for wood and V is the surface velocity in feet per minute. This, as just found, is approximately 19,000 feet per minute, so substituting its value, we get 812.25 pounds per square inch. Wood will not stand such a strain.

Torque cannot be overcome by turning the steering wheel to the right or left, as per Mr. Bissell's naive suggestion, for torque is a positive and definite force, and the simple movement of a wheel would neither add to nor subtract from its amount, action, or direction of action.

Counterboring of Engine Cylinders

Editor THE AUTOMOBILE:

[2,253]—Will you please tell me in your columns of "Letters Interesting, Answered and Discussed" about the following matter: Which is it, if any, of the automobile manufacturers that have a counterbore in the ends of their cylinders, and why is it that all of the high grade makes do not have it, as it is in all high grade steam engines, for there must certainly be some wear on the cylinder walls, where the piston and piston rings travel? I have spent part of my life amounting to about 20 years operating steam engines and similar machines, and in every case where the cylinders had no counterbore, the same would give trouble after they were used some length of time. W. S. REED.

Smyrna, Kent County, Del.

The writer of the above letter must be misinformed, for the great majority of gasoline engine and automobile manufacturers have the cylinders so cast that there is a natural counterbore formed at the upper end; either that, or the counterbore is machined in the casting. If this were not so, it would be impossible to machine the inside of the cylinders, as they are machined with a boring mill and an inserted blade cutter, or something on that order. In case no counterbore were left in the casting, the boring would not stop at the right point, and the piston in its travel would be likely to strike the unfinished part, causing trouble.

Moreover, were there no counterbore, the grinding process by means of which the cylinders are finished would bring out more trouble, for the grinding wheel, which is somewhat brittle in that direction, would break when the side of it struck the top of the bored part. Even of greater value than this is the matter of proper combustion chamber volume. If the cylinder diameter were not enlarged at the top, the length necessary to give the proper compression space would be excessive, resulting in very high cylinders.

Answered and Discussed

Four-Speed Gear with Two Direct Drives

Editor The AUTOMOBILE:

[2,254]—In several of the show issues of "The Automobile" there appeared an advertisement of a car, the "Keystone Six-Sixty," made by the Munch Motor Car Company, Yonkers, N. Y. Therein was mentioned that the transmission affords four speeds forward, with direct on the third and fourth, a feature which no other American shaft-drive car has. Could you give a full description of this particular transmission mechanism? Could you also publish a description of the Mea high-tension magneto?

New York City. A SUBSCRIBER.

At this writing, no details of the particular transmission gear mentioned are at hand, although the idea of two direct drives is not new, having been shown on a Hotchkiss car over three years ago. Other makers have also experimented with it, but apparently none of them found it of sufficient worth, or at least, in sufficient demand to be worth adding to the car as a regular feature. The main idea of a direct drive is that of reducing noise, and to some extent, friction, on the speed likely to be most used. Some makers consider this the high speed, and make that direct, while many more consider the second of four speeds as the one most used, and make that the direct, high in that case being a geared-up speed for exceptionally fast work. There are in this country 22 makers now fitting cars with four-speed gear boxes, and the fact that but one of them all uses the double direct drive speaks volumes for it.

The Mea magneto has been described in the columns of THE AUTOMOBILE on two occasions, being mentioned in the Boston Show issue, dated March 10, also this magneto was described in another later issue.

Peculiar Action of Confined Gasoline

Editor The AUTOMOBILE:

[2,255]—Possibly the following would be good reading for those who read articles under "Letters Interesting and Instructive."

In talking to a friend of mine who has the greater part of his life worked with oils, acids, etc., I mentioned the fact that I had filled a bottle with gasoline and corked it up tight and placed it in a cool pantry, when I went for it an hour afterward the bottle wss in a thousand pieces. This friend claims that it proves that the gasoline was doctored up with acid, otherwise it never would have acted this way. He claims that the gasoline dealers adulterate with acid in order to give it a higher test. He further claims the acid is very bad indeed for the engine. As a solution to test the gasoline for this acid he says that a few drops placed upon a varnished board and left for half an hour will show no bad effects upon the surface if the gasoline is free from acid, in fact, it brings out the color: on the other hand, if acid is present the surface will change color. Have any of your readers ever brought up this matter before and do you consider it a test worthy of investigation?

A cylinder jacket showing a crack four inches long through which only a drop of water seeps through every now and then, how can it be repaired? The crack is as fine as a hair and hardly think I could get "smooth on" or any other substance to penetrate the crack. The manufacturere advises me to get new cylinders, as brazing or pasting up the crack is money thrown away. What is your opinion? In case I fill the crack would you advise boring a hole at each end of the crack and putting in a bolt or screw to prevent it cracking any further. F. H. THOMPSON.

New York City.

The crack may be fixed, at least temporarily, by inserting in the water cooling system a solution, or powder, which will form a jelly or thick substance and fill up such small cracks as the one mentioned. One of these substances is called Sementol which is made by the Northwestern Chemical Company, Marietta, O.

In the Building of a Private Garage

EXPERIENCE must be taken advantage of in an undertaking such as this, and account must be taken of limited knowledge especially in view of the influence which public garages must necessarily have upon this phase of automobile undertaking. It is something of a question as to whether or not it pays to build and operate a private garage, if a public establishment of this character is located within a reasonable distance, provided it is run in accordance with the dictates of standard practice. It may cost from $25 to $35 per month to stable a first-class touring car in a public garage, and $300 to $400 per year seems to be a considerable sum to devote to this service.

In a public establishment, the monthly stipend pays for not only the housing of the automobile, but washing and polishing as well. In a private establishment, a car may fall into a low state of upkeep, if it is not promptly washed when it comes in off the road, or if it is improperly cleaned. In a private establishment, under the circumstances, while the monthly expenditure may be less than the figures given for the cost of stabling in a public garage, the fact remains that the cost of repainting

Fig. 1—Showing a limousine passing through the door with the front wheels on the runway and an incline such as will cause the back of the limousine to strike the top of the door framing

at the end of the year may wipe out the apparent saving, and the cost of replacing a disrupted cylinder might make heavy inroads besides.

When a car is placed in a private establishment, the facilities required for its proper maintenance must be provided, and unless the owner is fond of washing and cleaning the car, and is in a position to maintain the temperature of the garage above the freezing point throughout the winter season, he will have to cope with freezing troubles, which is a matter of removing the jacket water, or having to do with anti-freezing solutions, which latter products are not in the category of "all sunshine."

Simple Problem When Details Are Cared For

All the requirements in the maintenance of a car are simple, nor is there any mystery attached to the details involved, but the things to be done take on some of the characteristics which obtain in the maintenance of a horse; when feeding time comes, there is only one thing to do, that is, feed the horse. When an automobile comes in off the road, if it is besmeared with mud, it spells ruin to the finish on the body and the running gear, to defer the cleaning operation until morning. If it happens to be 10 o'clock on a raw night, after a 200-mile drive, it is highly improbable that the owner, if he acts as his own pilot, will accept the additional burden, which means that the automobile will be ruined if it is not cleaned.

If the owner is disinclined to give the automobile the attention it requires in service, one of two courses lies open to him. He may incur the extra cost of refinishing the car every few months, or he may engage and maintain a chauffeur. In the latter case, the cost of the private garage must include the salary and expenses of the chauffeur. If an owner elects to drive his own car, and desires to reduce the cost of maintenance to the lowest possible figure, the probabilities are that public garage service, if it is up to the standard, which is generally claimed for it, will compare favorably with the cost of a private establishment in the absence of a chauffeur, assuming, of course, that the owner will elect to retire for the night after he comes in off the road, rather than to stay up and clean the automobile.

All such problems will bow to common sense treatment, and a little investigation, and in all probability solution must be varied to suit the individual requirements, and the practical capabilities of the owner. In the planning of the structure, whether it is to hold a plurality of automobiles, or only one, the mere fact that the automobile to be stored therein is without a top, is not good reason for making the height of the door below that which will accommodate a limousine, and care should be exercised to have the door register with the greatest height likely to exist for any limousine type of automobile built. It is discommoding to discover that while the door is high enough to accommodate the owner's car, it will not let his friend's limousine in for temporary storage during a visit. In any case, the time must come when a car will cease to be valuable, and the new purchase may include an automobile with a top, when, if the door is not high enough, it is a little disconcerting and at some cost to prop up the structure, cut out for a new door, and have the new doors fitted to the enlarged opening.

Fig. 1 shows a condition which is brought about if the runway leading up to the door is a little steep, and if the height of the door gives bare clearance, measuring the body on the chassis in the vertical plane. When the front end of the car is tilted down, provided the wheel base is a little long, the back of the deck of the limousine will scrape against the door framing, with no good result to the car. This condition represents a practical

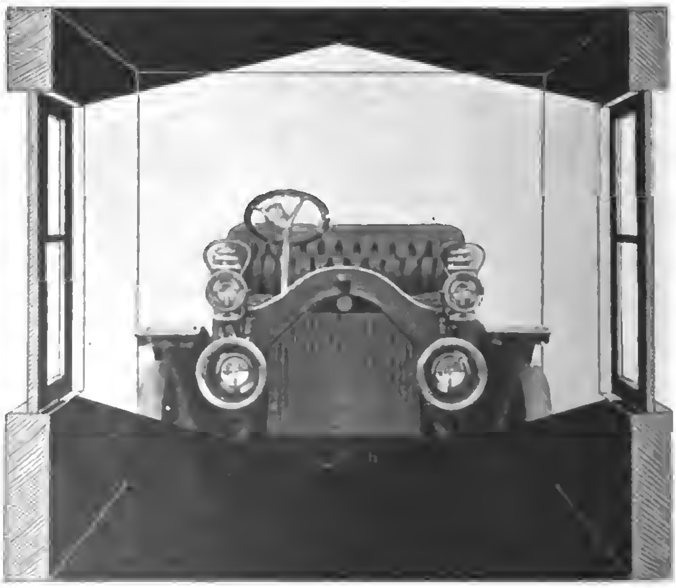


Fig. 2—Presents a narrow structure, with the windows the customary height, showing inefficient illumination with the machinery part in the darkness

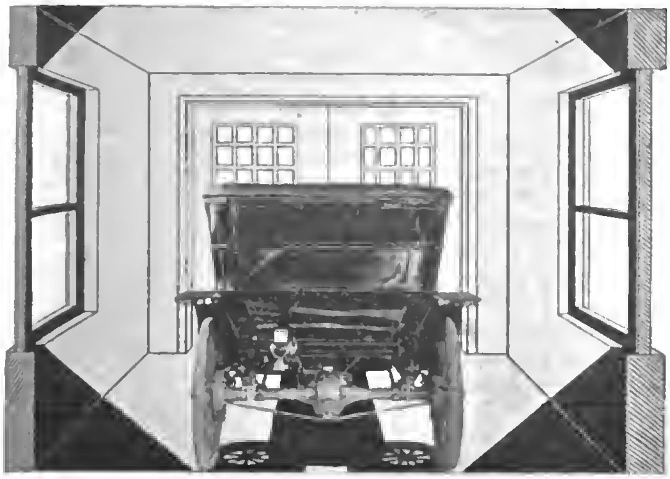

Fig. 3—The width of the building in proportion to the width of the car is such that the light strikes the floor outside of the line of the wheels with a good lighting effect

difficulty which was induced by the increasing length of wheel base in later day models of automobiles, whereas garages were built to accommodate earlier types of cars having a short wheelbase. This way of attacking the problem rather points to the futility of making the dimensions of the garage in bare conformity with the dimensions of the car. Liberal provision for a given type of automobile, while it represents very little by way of extra cost, takes care of the future, which, in view of the history of automobile designing, is the only safe thing to do.

Lighting Problems Influence Garage Dimensions

In congested districts, where space is at a premium, the owner who may have enough room for a one-car garage, is prone to limit the space to the barest necessity, and at first blush will reach the conclusion that a clearance on each side of the car, if it represents a comfortable passageway, is all that the occasion requires. As a dead-storage proposition, this is an excellent way of looking at it, but Fig. 2 is offered to show how the light from the windows, as they are usually placed, will fail to reach the vitals of the car, and will keep a large portion of the floor in utter darkness by contrast, so that if it is desired to examine the automobile, it will have to be run outside of the garage in order that the owner will be able to utilize daylight in the examination of the machinery, which, during inclement weather, is an undesirable act. In this kind of trouble, interior lighting whatever its character, aids very little, because of the shadows thrown.

By adding to the width of the building, provided the windows are to be the customary height from the floor, daylight may be utilized to better advantage, since it will strike the floor at a point outside of the line of the wheelbase of the car, as shown in Fig. 3, and, incidentally, more room will be found of advantage in many ways which do not appear upon the surface, even when a garage is being planned in the light of limited space, and perhaps with a view to limiting the expenditures as well. These lighting problems may be disposed of by taking advantage of artificial illumination, which adds to the cost of maintenance, and something of dangers, which will have to be recognized and treated according to their merits.

Artificial Illumination is a Necessary Evil

In case room is much restricted, the ill effect of a narrow space on each side of the automobile may be overcome by having the windows extend down to a point near the floor, as shown in Fig. 4. Another way to dispose of this angle of the situation would be to insert dead lights (the method of porthole lighting as used on ships) in the concrete work, having a row of these inserted lights built into the concrete all around within, say, 12 inches of the floor line. There is still another idea which is practiced to some extent in Germany, in which some of the blocks of concrete are displaced by blocks of transparent (glass) material.

While it is of the utmost importance to furnish windows and other means by which daylight may be taken advantage of to the maximum extent, primarily due to the fact that daylight is furnished free, also on account of the non-inflammable character of this sourse of light. Gasoline, as it is used for its fuel value in automobiles, is not at all dangerous when it is handled in accordance with its well-appreciated characteristics. The fact remains, however, that a very little liquid gasoline, if it is turned loose in a small enclosed room, becomes a source of danger in the presence of substantially every form of equipment used in the process of artificially illuminating. Substantially 2 per cent. of the weight of the air in a room represented by gasoline provides an explosive mixture, which is not only readily ignited, but sets free its energy with maximum force. In a small enclosure, it does not take a large amount of gasoline in liquid state to approach a condition of danger, and this will be particularly true if there are no outlets at the floor line, through which the vapor, as it forms, may spill out and float away on a current of air.

A Pit in the Floor Increases the Hazard

In former times when the working parts of automobiles were concealed under the deck of the body, and inaccessible, excepting by approaching from below, repair pits were much in vogue,

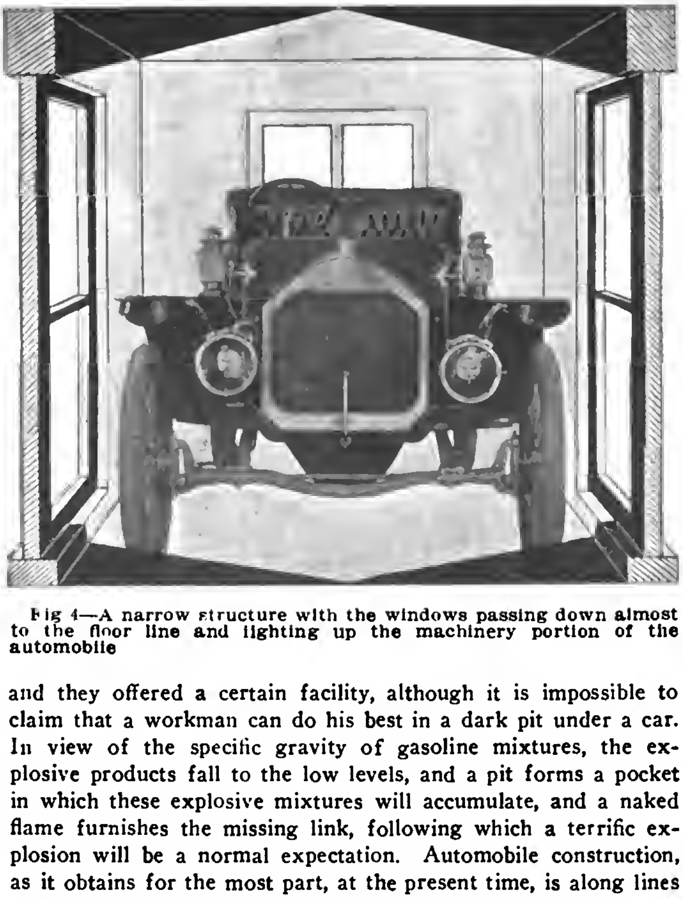

Fig 4—A narrow structure with the windows passing down almost to the floor line and lighting up the machinery portion of the automobile

and they offered a certain facility, although it is impossible to claim that a workman can do his best in a dark pit under a car. In view of the specific gravity of gasoline mixtures, the explosive products fall to the low levels, and a pit forms a pocket in which these explosive mixtures will accumulate, and a naked flame furnishes the missing link, following which a terrific explosion will be a normal expectation. Automobile construction, as it obtains for the most part, at the present time, is along lines which permit of getting at the working parts from above, and a pit becomes unnecessary if the automobile is properly made.

If a pit must be used, some means must be provided by which the accumulation of gasoline-tainted air will flow out from the bottom of the pit as fast as it may be formed, and it is highly improbable that a means may be readily at hand for the accomplishment of this necessary purpose, with sufficient certainty to make it desirable to plant a small garage in the vicinity of a dwelling house.

(To be continued.)

Long Island Automobile Club

TO those who have given the matter any degree of thought, the real purpose of an automobile club, its mission to motordom generally and the public at large, is beautifully exemplified in the work of the Long Island Automobile Club.

This organization is not a sporting club in the contracted meaning of the term; neither is it a map-maker and seller, and yet its influence in sport is far-reaching, and it has done a great work in making the highways of Long Island intelligible to automobile tourists, by its industry in placing signs.

Its real significance to motordom lies in its legislative activity, its social power and its service and convenience to those who avail themselves of its privileges. The club is almost ten years old, having been formed Nov. 27, 1900. It made a good start and soon swelled its roster to several hundred members. About a year ago it moved into its new quarters, situated at the gateway to Long Island, the plaza of Prospect Park, Brooklyn. It had about 400 members at that time, but now its rolls show that there are over 700, and before the last of this year a full 1,000 is predicted.

Historically, the club was the second organization in America formed in the interests of automobiling, and was the third to own its own clubhouse and garage. It has held and been identified with endurance runs, economy contests, race meets, tours and everything tending toward the uplift and development of motoring as a sport and pastime.

The club has three trophies for which the members contest annually, besides numerous prizes for the winners of races, runs and tours of various sorts. The three permanent cups are awarded as follows:

One handsome cup for the greatest mileage by a member during the year. In this contest the odometers are read May 1, and the owner of the car must be at the wheel in order to have the mileage count.

The second cup is presented to the owner of the car that tours through the largest number of States during the year.

The third cup is one presented by William Schimpf, but the conditions of its award have not yet been published.

In addition to these "annual" cups, the club each season puts on several runs based upon interesting conditions. The first of these for the present season will be the inter-club contest arranged between the Long Island Automobile Club and the Crescent Athletic Club, May 21 and 22. About a score have entered on each side, and the cars will be driven by active members of each organization. The system of penalization is mild. The total penalization of the contesting clubs will determine the winner.

The course of the run will be to Riverhead, via Easthampton and East Quogue, with check at the Long Island House. The return trip will be by way of Northport, and the total distance something under 250 miles. The trophy becomes the property of the club winning it twice.

While there is a strong probability that there will be some sort of a three-day run to end May 30, and another for July 4, the next event that is actually scheduled is the annual Orphans' Day outing, which will be given under club auspices June 7. This event is one of the most beautiful charities of its kind, and the interest in it is intense, not only from the viewpoint of the children, who look forward to the ride and the fun at Coney as the event of the year, but also by the members of the club who join to give the little ones a taste of real enjoyment. This year arrangements are being made to entertain 1,200 children and over 100 members.

At the Vanderbilt Cup race and other national events, the club provides its own pavilion for members, and assists them in every way to enjoy comfortably the big races.

The entertainment committee is one of the busiest organizations of the club. Twice a month there is "something doing" at the luxurious clubhouse. Two or three times a year the club indulges in "stag" affairs, but all its other social functions are open to the ladies. About once a month there is an able lecture delivered by some speaker of commanding knowledge of his subject. These affairs have proved very popular during the past year and have drawn large audiences. Aviation, ignition, mechanics, steel, rubber, law and motive power are some of the things that club members have heard discussed recently. Vaudeville is by no means unknown, and the lighter side of clublife is not neglected.

As a force exerted in the direction of reasonable law-making, the club shines. Every measure touching the interests of the automobile is scanned closely by the legal lights of the club, and the action taken to prevent imposition upon motorists is one of the refreshing things about its activities. Practically single-handed, the club has fought adverse legislation and unjust prosecution, and in a gratifying percentage of its undertakings it has been successful.

With regard to the pending Callan bill, the club has taken a strong position against certain clauses, and a series of compromises by which the original tenor of the bill has been modified to some extent, is claimed as an achievement for this organization.

The new clubhouse, a comfortable structure of modern architecture, is located at 920 Union street, within a stone's throw of the lordly entrance to Prospect Park. It is four stories above ground, with a basement, fully equipped for washing cars. The lot is 50 by 100 feet, thus giving the club 25,000 square feet of floor space. The club rooms are on the second floor and are

Entered at New York, N. Y., as second-class matter,
The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

THE farmers control the destiny of the automobile in proportion as they influence legislation, and that it rests in good hands is shown by the 2,000,000 miles of good roads that now offer an invitation to autoists to try out the newer mode of transportation. The automobiles for which farmers are willing to make expenditures for good roads are the very kind of automobiles which will be of the greatest benefit to the farmers. Short-sighted individuals may reach the conclusion that farmers will confine their interest to farm-wagons; they fail to give the farmers credit for having acumen enough to know that the banker must be taken to the bank; the banker's wife to the department store; the miller to the mill, and the money spender to the place wherein he will be accommodated in proportion to his ability to pay.

✦ ✦ ✦

JUST now there is a decided tendency to invest money in the manufacture of commercial vehicles, and that this year will see the commercial output go up on a basis of at least five to one, is predicted. It has taken all these years to bring about a realization of the fact that it is in the commercial vehicle that the future of the industry lies; a future in relation to which all attempts at prediction fall short, due to the vastness of the industry as it is reflected by the preparation which is now being made. Mistakes, as they were made in the past, and as they retarded the growth of the commercial phase of the industry, will scarcely have any influence on the future; if a storekeeper is now reluctant to put his deliveries on a basis which is possible with commercial automobiles, he will have to go down in the wreck of his business.

✦ ✦ ✦

FROM now on, for the whole of the warm season, contests will attract the notice of the makers and the users of automobiles to a greater extent than ever before, and it is well for the industry that all contests for the year will be conducted in accord with the rules of the "Contest Board." Chairman S. M. Butler has the matter well in hand; the rules are better than they ever were before and the chances of having a car of no merit receive credit for what it is not capable of doing at all are sufficiently remote to be disregarded. The Contest Board is the creation of the honest makers of automobiles who desire to maintain a condition of glowing health in the industry and they prefer to put the whole matter in the hands of a board of control, under the guidance of a chairman who understands his business and is known for his competence to act for the best interests of the industry, rather than to go in for the old time squabble and unfair rulings.

✦ ✦ ✦

AFTER awhile, when the makers of automobiles have a chance to breath, it is believed that the question of standardization will be given far more thought than it has heretofore received. Perhaps the Society of Automobile Engineers will take the matter in hand. President H. E. Coffin is the right man in the right place and it is assured that he fully realizes the necessity of clearing up many of the questions of standardizing which now hamper makers of automobiles, especially as they relate to the procuring of material. As it is at the present time, certain of the materials used in the construction of automobiles are difficult to procure, merely because the sizes specified by the engineers who are responsible for designing are so numerous that the mills are compelled to fill orders after they are received rather than to stock up. Certain sizes, referring to the respective materials, are carried in stock, and it is believed that designers might find it convenient to specify just these sizes when making out lists of materials required, in which event the mills would be enabled to make quick deliveries, and, what is more to the point, work on stock orders during the slack season with a chance of lowering the cost.

✦ ✦ ✦

YEAR after year the automobile situation has had its serious phase as represented by pneumatic tires, and for a long time it was considered necessary to try to find some substitute for Sea Island cotton and Para rubber, on the ground that these materials would never prove satisfactory for the character of the work imposed upon them. Time has shown that our worries were attached to the wrong chariot; the real question is, how may the price be held down to a reasonable level in the face of a scarcity of both cotton of the desired grade and rubber of suitable qualities? This great question is about to receive the distinguished consideration of the Association of Licensed Automobile Manufacturers, and it no doubt has worried the tire makers more than a little.

S. A. E. Activity Along Broad Lines

RING has been given an impetus by the coming
utomobile, which, from the point of view of history,
equalled when the electrical art became the foun-
eat industry. The other day it was said that the
moved up so that it stands as the fifth industry of
night have been stated at the same time that en-
along transportation lines, which were con-
e automobile, became responsible for what is
the fourth industry of the world. In the com-
e prosaic and hard-working engineer finds him-
or another classified in a manner as follows:

New York, there was so little interest
e held over so that Mr. Riker served
ver president for the second year.
of the second year of the Society
e fact that the Mechanical Branch
he industry, it was rendered apparent
direction of companies, as in the Me-
or less handicapped, and the character
d through such an association is only available to the companies involved; morever, it is plain in the light of experience, that commercialism puts limitations upon the members. During Mr. Riker's second year, matters took on a more serious phase, and the membership of the Society grew sufficiently to warrant further activity, so that at the second annual meeting which was also held at the New Grand Hotel, New York, plans were made for a campaign of education, and a new set of officers were elected for the ensuing year with instructions from the Council to increase the membership in every way consistent with the high aims of the Society, with the result that the third annual meeting brought together upwards of 280 of the first engineers in America.

This last year, under President Henry Hess, has seen the crystallization of many of the important phases, the entire elimination of the idea that engineers should be in any way tied to companies when they go to meetings, and while it is true that the Society has not doubled its membership within the last year, it is equally true that it has advanced the position of automobile engineers so that they are no longer under the shadow of the salesman, whose advantage lies in the fact that he has his foot placed directly and firmly on the money bag.

For 1910, the new officers included H. E. Coffin as president, and that this was a wise choice is being proven at every step. In the past, the work of the secretary has been done by voluntary service for the most part, although it is true that some payment was afforded to the secretaries of the last two years, but it was found that the best interests of the Society would be realized were the affairs of the same placed in the hands of some capable man at whatever cost. What Mr. Coffin proposes to do to satisfy this important situation is to put enough of stability into the situation to make it possible to engage and pay for the most capable managerial secretary possible.

With this idea uppermost, President Coffin approached Coker F. Clarkson, who will be remembered as the Assistant General Manager of the A. L. A. M., and it is now announced by the A. L. A. M. that Mr. Clarkson has severed his connections therefrom, with the understanding that he is to assume new and important duties in connection with the Society of Automobile Engineers. Mr. Coffin, at a recent meeting of the Council of the Society, expressed himself in relation to the future activities in fitting language as follows:

"The fast-growing motor car industry now stands, I believe, fifth in the schedule of the world's greatest industries, and no single branch of it out-ranks in importance the engineering.

"Among the main functions of the present and of the future of the S. A. E. are the publication of a digest of current technical literature; a bureau of technical information; collection of data for a standard handbook of motor car design; exhaustive motor and metallurgical tests; an intelligent direction of the work of standardization of automobile materials, parts and accessories; a comprehensive card index of automobile engineering; the presentation and discussion of technical papers of the highest class.

"We must place in active direction of this work a man of a rare combination of training and ability. He must have had experience in this line of endeavor and an adequate knowledge of automobile engineering conditions; he must be an organizer capable of originality, and above all he must be a tireless worker. We believe that we have the right man in Coker F. Clarkson."

The S. A. E., having 350 members, is absolutely representative of its field, and is without a rival or competitor, having maintained its identity and individuality, as it will continue to do. Most of the men experienced in automobile engineering are active workers in the society, and have a deep-rooted professional interest in it. Fifty new members have voluntarily joined the society since it became known that Mr. Clarkson was to direct it.

Collapse Foretold for Artificial Rubber Market

Price Level Outrageously High Trembles on the Pinnacle

A. L. A. M. Calls Meeting While Tire Makers Shun Buying in the Corner

HANGING by a single thread, the whole rotten fabric of the present manipulated and cornered rubber market is dangling and ready to fall, like an over-ripe and fly-blown peach.

Cable advices from London tell of another slump in crude rubber and another drop in the inflated issues of various companies that are alleged to produce it, but the most significant thing about the market abroad is the fact that American manufacturers will have nothing to do with it. In fact, the buying orders at present levels for crude are so small that something akin to dismay has already begun to find entrance into the minds of the speculative public of England.

The situation is critical and a decision on the part of the automobile tire makers of America not to submit to the exorbitant prices asked now, would undoubtedly lead to a crash that would make the South Sea Bubble's explosion seem like profit taking on a small line of long stock.

A. L. A. M. Calls a Special Meeting.

Such a decision is not unlikely to be announced at any time and indications point to some such action immediately following the meeting of the A. L. A. M. next Wednesday. The association has been called together to consider ways and means of providing tires for next year's turnout and the situation has developed a number of unusual angles.

The price of rubber is so high now, due entirely to the artificial conditions that prevail abroad, that tires made of crude rubber purchased at present price levels would be a prohibitive luxury. Consequently the tire makers are loth to buy.

The tire makers and the Association are really not at odds over the situation, and the proceedings of the meeting will probably uncover a common ground of defense for both sides.

The effect of an agreement not to purchase at this time would have a very definite result in the market. England has been crazy over speculation in rubber shares and crude rubber for months and many big fortunes have been made. As far as the purchase of shares in companies that are actually producing rubber is concerned, the movement had more than a tinge of legitimacy, but as the prices soared, the general public, including charwomen and hackdrivers and ill-paid clerks went into it with all the resources they could command. Much of the speculation was conducted on margin and on the installment plan, and yet the shares continued to climb.

But now, the first "bear" news has arrived and the market for both shares and crude rubber is hanging and drooping at the summit of the pinnacle. One little touch; one little breath, and the gold-mad gamblers will be engulfed in the most sudden crash ever witnessed in stocks.

If such a result only affected the rubber gamblers it could be viewed with equanimity by the public at large, but when the pyramided long accounts begin to crumble, the first effort will be to bolster them up with real collateral, including the British holdings of American dividend-paying securities. It may be predicted with certainty that in the event of a crash, wild-cat rubber shares will not be valuable enough to paper a spare-room in a New England farmhouse. Rubber itself has an intrinsic value and will always be in good demand, but its price will have to come down to something like an equitable basis before the demand for it will revive after the smash in shares.

A special meeting of the board of managers of the A. L. A. M. has been called for Wednesday, May 11, and according to the official announcement, one of the important things to be considered at the meeting will be the tire situation.

"This is extremely critical," says the letter sent out by the association, "and one that demands consideration at this time by the entire membership, as it affects every manufacturer as well as the present and future owners of motor cars.

"In this connection, it is requested that each board member before attending the meeting, will endeavor to investigate the rumors which are current to the effect that there exists among certain tire manufacturers of this country an understanding or 'gentlemen's agreement,' to increase the price of tires and to refuse to sell or deliver to manufacturers at this time any tires for 1911 equipment.

"It is hoped that you will obtain all the information available relative to the tire situation, so as to be prepared for an open discussion at the meeting, which promises to be one of the most important, from a makers' viewpoint, that the association has held.

"A number of other important subjects will come up for consideration at the meeting."

Tire Makers Advance Ideas; Will Not Be Quoted

The tire men shed some light on the subject and one of the prominent members of that branch of the trade said: "The present condition of the crude market, is, we believe, manipulated and far above legitimate levels. We sympathize with the automobile makers and appreciate their wish to contract for tires for their 1911 output, but our whole effort at this time is to avoid purchases of crude rubber while the market is in a cornered condition.

"If we contracted to sell tires right now, we would have to double the price asked last year, because of the remarkable rise in the crude material. If we contracted to sell at the prices of last year, we would all go broke if we had to buy our crude under current conditions.

"Consequently, we want to simply stand by for a while and wait for the bubble to burst.

"Reckoned on the price of crude rubber to-day, the price of tires would be practically prohibitive. We realize that fact and are quite as much interested in correcting conditions as the A. L. A. M. can be."

Tire Maker Tells of Conditions

F. A. Seiberling, president of the Goodyear Tire and Rubber Company of Akron, O., has given out a statement in which he says: "High prices prevailing for crude rubber are fairly attributable to two primary causes: First, the abnormal draft upon the world's supply; and, second, the wild speculation in rubber and rubber shares in England."

In the meantime, the consolidation of the Massachusetts Chemical Company, the Walpole Varnish Works, the Walpole Shoe Supply Works, all of Walpole, Mass.; the Valveless Inner-tube Company of New York City, and the Walpole Rnbber Company of Granby, Quebec, has been announced. The consolidated concern will be known as the Walpole Rubber Company. The factories are at Walpole, Mass., Boston and Quebec with branches at New York, Chicago and London. A new factory building has been started at Walpole which, it is announced, will have a floor space of 100,000 square feet. The company makes, among other things, a seamless automobile tire.

Detroit Automobile Makers Pushing Deliveries

May 2—Activity in automobile manufacturing

itomobile garages in the United States will
this Summer, on property recently pur-
evard and Woodward avenue, according
of Thomas D. Buick, president of the
arage Company, of Saginaw, which was
nths ago. The property purchased comprises 36,750 square feet, nearly all of which will be covered by a fireproof two-story structure, 100 by 245 feet in size.

The Regal Motor Car Company, of Detroit, is building another addition to its plant. This new structure is a combined brick, steel and concrete construction of the latest type, covering an area 249 by 598 feet.

The Taxicab Co. of America has purchased the building formerly used by the Henkel livery, and is equipping it as an up-to-date garage. The Henkel barn was recently the scene of a dispersal sale of horses and cabs, the business being given up as no longer profitable, since the advent of the taxis.

Alexander Byron Mohler, representing Mohler & DeGress of Mexico City, the largest dealer in motor cars in old Mexico, has been spending several days in Detroit, the guest of officers of the Hudson company. He says there are 2,300 cars in the City of Mexico, but warns manufacturers that nothing but sturdy cars will appeal to the purchasing class there, due to the altitude, the road conditions, and the amount of hill-climbing necessary to any prolonged trip.

The Sibley Motor Car Company has purchased a factory at Solvay and Mackie avenues, on the West side, and will start immediately installing machinery for the production of 2,500 twenty-horsepower pleasure cars. The facilities are considerable at the new location, the plant itself being 60 by 280 feet in size and the deal by which it was secured bringing with it two acres of ground, providing room for a large amount of expansion. The property adjoins the Wabash and Pere Marquette tracks and affords ideal shipping privileges.

Among the recent incorporations were the following: Oliver Motor Car Company, $300,000; Detroit Carbureter Company, $25,000; Johnson-Kellam Motor Sales Company, $10,000; Rotary Valve Motor Company, $100,000, and Robison Motor Car Construction Company, $20,000.

promised.

Fuller Buggy Company Prices

Two of the models by the Fuller Buggy Company of Jackson, Mich., were illustrated in the April 21 issue of this journal. The price of one of these models, which is fitted with solid rubber tires, was given as $1,500, and that of the other as $2,000. These prices should have been $850 and $1,165, as stated in the company's new descriptive catalog, which also illustrates and describes six other models, including one delivery models, including one delivery wagon. In this total of eight distinctive cars, two are equipped with a four-cylinder motor of 25 to 30 horsepower, while the other six, including model K, touring car, and model F, runabout, and the four models shod with solid tires, have a 22 horsepower engine of the two-cylinder, horizontally opposed type, placed crosswise under the hood.

Makers Forming an Association

Some progress has been made in the formation of the new automobile manufacturers' association in Detroit. The concerns so far identified with the project are the following: Anhut Motor Car Company, Carhartt Auto Company, Demotcar Company, Flint Wagon Works, Imperial Automobile Company, Paige-Detroit Motor Car Company, W. A. Paterson Company and the Warren Motor Car Company.

Woman Starts Across Continent

Miss Blanche Stuart Scott, accompanied only by her maid, left New York May 1, in an Overland 38, en route to San Francisco. No time limit has been set for the trip. If she is successful, Miss Scott will receive $1,000.

Philadelphia Activities on the Increase

PHILADELPHIA, May 2—Some idea of the activity of the various borough and township officials hereabouts in keeping tabs on automobilists may be gathered from the warning issued last Saturday by the Automobile Club of Delaware County giving details of the location of no less than 48 speed traps on the roads radiating from the city into the surrounding country, and within less than a score of miles of the City Hall. The warning notice also specifies a score or more of places where the officials are strictly enforcing the "Blow Horn" law; those localities where the powers that be are inclined to be lenient are also mentioned. The club is following up its good work along these lines by posting flagmen (at its own expense) on the more-traveled roads.

Much chagrined by the eleventh-hour decision of the Contest Committee of the Quaker City Motor Club not to include a commercial car class in last Saturday's roadability run to Atlantic City, Manager Daniels, of the Philadelphia Buick branch, will endeavor to bring about a contest on similar lines open only to various classes of self-propelled business wagons.

The Taylor Motor Distributing Company, agents in six States for the Warren-Detroit "30" and Matheson cars, and with Philadelphia as its distributing center, is now fitting up the entire ground floor of the big concrete building at Nos. 210-212 North Thirteenth street as its main headquarters, and will give up its temporary offices in the Real Estate Trust Building at the close of the present week.

South Bend Is Active Automobile Center

SOUTH BEND, IND., May 2.—Marvin Coppes, agent for the Chalmers-Detroit and the Hudson, and M. G. Smith, who has been chauffeur for Col. George H. Studebaker and in the testing department of the Studebaker Automobile Company, have formed a partnership and will open a garage at 333-335 South Main street, South Bend, the location being that occupied until recently by the White garage. The men will handle the machines for which Mr. Coppes is agent. Mr. Smith will look after the repair and mechanical department, and Mr. Coppes will have charge of the sales department. Mr. Coppes whose home is in Nappanee, Ind., will move to South Bend.

Glidden Pathfinder on the Homestretch

EMPORIA, KAN., May 4—The Pathfinder arrived here this afternoon after a 120-mile spin over roads unexcelled anywhere on the 1,900-mile route thus far. The Chalmers was piloted from Caldwell to Wichita and Emporia by Sam Hess of Wichita. An escort from the Kansas City Automobile Club met the trailblazers here and will lead the way to Missouri.

WICHITA, KAN., May 3—The final 1,000 miles of what is to be the longest of any Glidden tour was entered to-day by the pathfinding car, which ran from Enid, Okla., to Wichita, a distance of 115.8 miles, over roads which are on a par with the first section of the 216 miles run from Oklahoma City to Wichita.

There was something resembling a cloudburst in this district Sunday night, but it did no damage to the hard dirt highway.

Caldwell, an old-time cow town from which the glamour has been rubbed by agriculture and prohibition, was the first place passed after the pathfinder left Oklahoma this afternoon.

Scene in Busy Dallas, Tex., Upon Arrival of Glidden Pathfinder

Change in Official Makeup of A. A. A.

Frederick H. Elliott has resigned from the secretaryship of the A. A. A. Robert Bruce has succeeded to the place thus made vacant.

Pathfinding Car Arriving at Huckin's Hotel, Texarkana, Tex.

Paulhan Breaks Record; Wins $50,000

Louis Paulhan, aviator, broke the cross-country flying record for heavier-than-air machines when he flew his big Farman biplane from London to Manchester, 186 miles, making two stops en route.

Paulhan won a purse of $50,000 which had been offered by Lord Northcliffe on behalf of the London *News*. The French aviator came near having company on the flight, for White, the British enthusiast, starting nearly twelve hours after the Frenchman, made a gallant effort to accomplish the same trip.

Paulhan was greeted with a tremendous ovation when he gracefully guided his machine to the ground at Manchester He complained of the bitter cold of the upper air.

The third annual Hill Climb of the Yale University Automobile Club will be held on Shingle Hill, June 7. The contest will be given under the auspices of the A. A. A. and the referee will be C. H. Gillette, president of the Hartford Automobile Club There will be nine classes.

The first annual Hill Climb, to be promoted by the automobile dealers in Paris, Ill., will be held at that city May 11. Silver loving cups will be awarded the winer of each event, a fifteen-inch cup being hung up for the Edgar County championship.

Atlanta Event Has a Representative Field

THE three-day race meet, which opens on the speedway here to-morrow, does not give promise of being so big an event as the opening meet last Fall, when practically existing speedway records established at the Indianapolis speedway were shattered. Since that time, however, the mile board track at Los Angeles has sprung into existence and holds many of the free-for-all records established last Fall at Atlanta, so that the big thing with many who are here waiting for the three-day programme to open is, what board-track records are going to be beaten at this meet. So far as entries go the meet which will open to-morrow promises a disappointment in that the field will not be as big as it deserves tó be. The programme for the three days shows 20 events in all, seven of which will be run on Thursday, and in these there is a total of 23 cars entered, or little more than three cars to the race. One reason for this small entry list is the refusal of the management to give appearance money. Many drivers said they would bring their cars down if they were given from $1,000 to $1,500 appearance money, and in addition, have their hotel expenses paid, as well as the expense on their cars to and from Atlanta. This, the management refused to do, on the just grounds that it wants to encourage stock car contests. In spite of this handicap, the field is a representative one and includes such cars as Marmon, National, Fiat, Stearns, American, Cole, Pope-Hartford, Knox, Allen-Kingston, Buick, E-M-F, S. P. O., and Firestone-Columbus. Although one or two makes represented last Fall have not arrived, the number of each make present is sufficient.

The programme includes two excellent events, both 200-mile races for special speedway trophies. Both are new trophies, and were not contested for at the meet last Fall. It was the intention to have the two big trophies put up last Fall, contested for this Spring, but both the Buick and Rainer people claimed they had a right to hold their trophies for one year and refused to allow them to be raced for at this meet. As a result two new ones have been made, each costing approximately $3,000, and of better value than those of last Fall. Each will have to be won three times in succession. One is known as the Atlanta Speedway Trophy, and will be raced for Thursday, and the other, Atlanta Automobile Association Trophy, will be raced for on Saturday. The Thursday race will bring out two Nationals, one Knox, one Marmon, and one S. P. O. This is for cars rating at 301 to 450-cubic-inch piston displacement. The Saturday race is for 451 to 600 Class and has a good entry list. Of the 21 events listed for the three days, ten will be strict stock-chassis events, and the stock requirements of the cars will be gone into with the greatest care. It might be remembered here that at the Los Angeles board-track meet not a single stock-chassis event took place, so that not one of the stock-chassis speedway records have been effected.

Capt. William Mitchell Lewis and Family Sailing for Europe

C. M. C. Completes Important Sign Work

CHICAGO, Apr. 25—Saturday marked the completion of the first step of the Chicago Motor Club's signboard campaign, when the last of the four routes selected for by the local organization, the one to South Bend and return, was finished. This work has been delayed by the severe winter. A two-ton Rapid truck, donated by Siegmund-Baylies Company, of Chicago, agent for the car, helped the motorists in carrying on this work.

The truck has been on the road for a week now and the latter part of the week it encountered the snowstorm, but despite this handicap it daily carried a heavy load of signs and posts and finished the task on schedule time.

The Chicago Motor Club now has spent more than $2,000 in erecting signs on the roads leading into Chicago. It has put seventy-eight signs on the Lake Geneva route, sixty-nine on the South Bend, 110 to Beloit and eighty-three on the Milwaukee stretch. Now there are signs on 369 miles of roads in this vicinity, and the club has marked the four main arteries of motor traffic running into the city.

The new plant of the **Victor Lamp Company** at Cincinnati is ready for occupancy. The company is turning out equipments for 300 automobiles a day and when the whole factory is in full operation, there will be about double that number produced.

Effimoff Wins Everything at Nice Meeting

This picture shows a remarkable scene. Three areoplanes are in full flight along the edge of the sea at Nice. The one in the foreground is Effimoff, in his Farman biplane, speeding along the beach. The one to the right is Latham in his Antoinette monoplane, and the distant gull-like figure is Olieslagers in his Bleriot monoplane.

Capt. Lewis Sails Abroad for Rest

Captain William Mitchell Lewis, president of the Mitchell Lewis Motor Car Company, with his family boarded the Cunarder Mauretania just as she was preparing to sail for Europe, where Captain Lewis and his party will enjoy an automobile tour and other recreation under most auspicious circumstances.

Remarkable Aeronautical Picture Taken at Nice Aero Meeting

Hub Doings Attract Much Attention

BOSTON, May 2—The legislative committee that heard the motorists on proposed changes in the present law, made their report last Friday when a draft of a bill was sent to the House and Senate. When the motorists realize what the bill provides they will not be pleased. There are some commendable changes such as not compelling chauffeurs to wear badges; a clause under which many of them were fined, frequently, and allowing number plates to be 48 inches from the ground instead of 36. But the two clauses in which most motorists were interested, the revoking of the section compelling the blowing of horns at every intersecting street, and the reciprocity clause allowing non-residents the same privileges that their States give us, are not what was expected. The latter is particularly bad, for under the guise of a reciprocity clause the committee has reported a change that simply draws the lines tighter and says no non-residents shall operate for more than 10 days in any one calendar year. Then follows the psuedo reciprocity clause, providing that other States from which non-residents come grant the same privileges to our motorists, with the highway commission as final arbiter. So it matters not that Maine allows Bay State men to roam all over its State without restrictions; that New Hampshire allows them to go in and out as often as they want unless they stay 10 consecutive days; and that Vermont allows them to travel around from 10 to 60 days, the Massachusetts legislature under this law proposes to say to them: "Thou shalt not cross our border more than 10 times without paying tribute, no matter how liberal your States are to our motorists." It is a most unfair advantage and will lead to a lot of trouble, for motorists in those states, who traded in Bay State cities, will refuse to do so and look around to make purchases at home. The first draft of the noise-making clause attempted to bar the blowing of some of the well-known makes of horns in the different cities and towns, but this has been modified. There is also a clause forbidding motorists to allow too much smoke to escape.

If the plans outlined by Chester I. Campbell, manager of the Boston motor shows, materializes there will be a real outing for children this year in the Hub on June 8 which will attract much attention. In other years the dealers were the only ones who could be induced to loan cars and the limit generally was about 25, so that about 125 youngsters were all that enjoyed an outing. These comprised blind children. Mr. Campbell now thinks that he may be able to reach a sufficient number of owners to insure a better showing. Last Saturday he sent out 2,000 letters to Boston motorists asking them to help this worthy cause and if the number of cars are sufficient more than 800 children will be taken care of on a trip to Sharon. In addition to the blind children it is planned to give the crippled children an outing.

Delaware Valley Run Decided

Around a figure eight course, the crossroads of which were at Trenton, N. J., the Delaware Valley Endurance Run was successfully held Tuesday. The entries, numbering 24, were divided into three classes as follows: Class A, cars valued at $2,001 and over; Class B, from $1,001 to $2,000, and Class C, $1,000 and under. Class A and B ran 300 miles, three times around the course, and Class C traveled 200 miles. Four cars in Class A finished with perfect scores: Speedwell, Locomobile, Sharp Arrow and Crawford. In Class B, two Mercers were not penalized and in the other class a Maxwell had a perfect score. Twenty-one out of the 24 starters finished the run.

Quaker City Third Annual Roadability Run

(*Continued from page* 831)

After checking in, the cars were trundled around to Young's Million Dollar Pier and were parked in the big ballroom. At least many of them took advantage of this arrangement, although a few turned around immediately after the finish and started back for Philadelphia.

The scene on the pier was one full of life and color. The cars, including many of the well-known makes and styles, were stationed in lines and series and presented a brilliant picture to the eye of the observer. A big crowd assembled at the Strand, the streets were filled with sightseers, the boardwalk was comfortably filled and the automobile was the center of attention.

Up to the moment of the official announcement, those who had been successful in winning one of the coveted cups were in complete ignorance of their success.

After the clerical work had been cleaned up, hands adjourned to Young's Pier where Mayor Stoy made the announcements and felicitated the winners and those who did not win.

The cups awarded were as follows: First prize, Mayor Franklin P. Stoy's cup; second prize, the Hotel Strand cup; third prize, President L. D. Berger's cup; fourth prize, the Hotel Walton cup, and fifth prize, the board of governor's cup.

The officials who had charge of the run were as follows: Honorary referees, Mayors Reyburn and Stoy; assistant honorary referee, Alfred E. Burk; referee, R. E. Ross; official starter, G. Hilton Gantert; associate member contest board A. A. A., P. D. Folwell; official timer, Paul B. Huyette; pacemaker, J. Fred Betz, 3d; press, George M. Graham and Secretary Harry C. Harbach.

The reception committee at Atlantic City consisted of the following: Harry B. Cook, C. Stanley Grove, Walter E. Edge, Warren Somers, Louis Kuehnle, David R. Barrett, Philip B. Grove, Col. Lewis T. Brown, M. B. Woodruff, S. S. Phoebus, Jacob Weikel, Harry Wootton, C. D. White, Col. Thos. Potter, Jr., Frank B. Off, A. J. Royer, William J. Black, Edward S. Lee, Henry Bolte, Jr., Charles R. Myers, Isaac Bachrach, George W. Carmany, Howard Bennett, Gustave Kessler and Martin E. Keffer.

Paul B. Hayette, president Timers' Club

The Regal "Plugger," decorated with credentials from various cities in which it has visited recently was the object of considerable interest at the start and finish and along the way. During Saturday night and Sunday an impromptu automobile show was held on the steel pier under the auspices of the Automobile Trade Association.

Long Island Automobile Club

All told, the garage equip- is sufficient to accommodate seventy-five cars. ıll occupied. The charges are moderate and facility for furnishing oil and gasoline, and supplies of other kinds.
'on, and a big elevator for communicating be- floors of the garage, complete the facilities

he Long Island Automobile Club includes New York State Automobile Association and the A. A. A., with all the influence and advantage that may accrue from those connections. The utility of the club is shown emphatically in one direction. Arrest is not impossible to the most careful driver of an automobile. It may come at a time when the motorist does not happen to have the formal but necessary $100 in his pocket to be used as bail. In that case, the member of the club has only to telephone to the club house, and a surety bail bond will be filled out and rushed over to him.

The club held the first 100-mile endurance test ever held in America and the first one-mile straightway speed contest over the Coney Island boulevard, and has handled numerous other important and epoch-making events.

The officers of the club are as follows: Allen C. Aldermen, president; Louis T. Weiss, vice-president; Charles C. Cluff, treasurer, and C. Stewart Cavanagh, secretary.

The Board of Governors: Herbert G. Andrews, Dr. H. R. Price, Dr. William P. Richardson, Frank G. Webb, William Schimpf, and Dr. C. B. Parker. The manager is Charles S. Ellis.

The heads of the various standing committees are: C. Stewart Cavanagh, House; Frank G. Webb, Entertainment; William Schimpf, Garage; Louis T. Weiss, Contest and Tours; Charles Jerome Edwards, Good Roads; Jay S. Jones, Press; Allen C. Alderman, Membership; Louis T. Weiss, Technical; Herbert G. Andrews, Law and Legislation, and Dr. H. R. Price, Finance and Auditing.

Best Means for Dustproofing the Highway

(*Continued from page* 845.)

perhaps particularly unreliable, because e economical work methods which should have been applied only under European have this improved machinery, or some- tter, applied in America under test con- olves of saving in dustproofing materials to be one of the most important require- in the cause of dustless roads.
records vary so widely and fail so uni- as on maintenance cost, and the failure to lack of time, but mostly to lack of possibly lack of appreciation of the al- ıate relations which exist between the the cost of the maintenance. As types h reference to the heaviest and fastest ıin, and the proportion between heavy t vehicles is nearly constant on any ving the average number of vehicles day, month or year would be of the inging the available data on mainte- mon basis for comparison. The little his respect tends to show that on all l maintenance cost are nearly pro rata of the traffic, after this reaches 500 ve- umed that no road carrying less than sually be considered in a dustproofing ost at this volume of traffic should or an estimate, and it has been so sketch for a schedule. For this nance cost will appear low, in com- ed on denser traffic, and the cost of relatively high, as the figures for the ı data from stretches of roads where its volume could not be taken into proper account, because it was not given. Whether the cost of dustproofing processes increases pro rata with the traffic or at a much slower rate, is a question which it seems impossible to even guess at, for the present, but those competent to prepare a complete and technically correct schedule will doubtless be able to fix a ratio which will be sufficiently accurate.

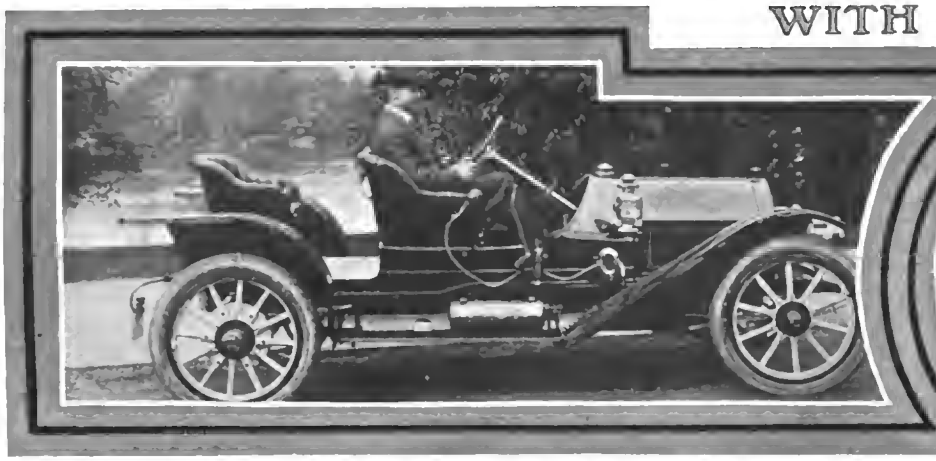
In applying even a corrected schedule, however, to a road project and trying to decide in advance what the maintenance cost will be for the completed dustless road, it will probably be safe to assume that any country thoroughfare, so situated that it requires to be made dustless, will attract one hundred per cent. of additional traffic from neighboring roads, as soon as the improvement is made; and at this point one discovers an advantage in the dustless thoroughfare which has been little noticed.

All the domestic data of maintenance fail to take account of one element in cost reduction which has been well demonstrated in Europe. Any system of regular and continuous maintenance, such as is made possible when financial provisions are made in advance for a period of twenty years or longer, results in a compacting and adaptation of the roadbed to its traffic, which gradually reduces the average cost of the maintenance below any estimate based on data from the first five or ten years of the road's existence.

Worcester Dealers Organize

WORCESTER, May 2—The Worcester Licensed Automobile Dealers Association has been organized with six firms as charter members. The members are: Lemont Motor Car Company, John S. Harrington, Worcester Motor Car Company, Macker-Tyler Company, Harry J. Murch, and Norcross Auto Company. Officers: President, B. A. Lemont; vice-president, Fred B. Williams; secretary-treasurer, Oliver P. Tyler; clerk, Jay Clark, Jr.

WITH THE AGENCIES



Joseph Tracy, of New York City, the well-known automobile engineer, at the wheel of his Chalmers Thirty runabout, in Central Park

Peter S. Steenstrup, of Hyatt Roller Bearing Co. and Nat. Association of Manufacturers

E. M. Long & Sons have assumed the Overland agency at Cadiz, Ohio, for Harrison county.

H. J. Smith, Cleveland, has been appointed Regal agent for Ravenna and surrounding territory.

E. L. Leinbach & Co. have moved the local Matheson car agency to 21 East North avenue, in the rear.

Will J. Friel has taken the agency for the Overland at Marietta, Ohio. He will cover several counties in Southeastern Ohio.

The C. N. Lippart Auto Company, of Lorain, Ohio, was incorporated with a capital of $5,000 to do an automobile business.

Another new agency in Pittsburg is that for the Pullman car, which will be at 6113 Centre avenue with J. E. Graham in charge.

Reis & Co. have assumed the agency for the Warren-Detroit Car in Baltimore. The salesrooms and garage are at 21 East North avenue.

The Only Car will be handled in Cleveland by J. H. Anderson. The car sells for $700 and, its makers claim, has a rating of 60 miles an hour.

J. A. Boyd has organized the Commercial Auto Sales Company for the sale of Chase delivery wagons and Gramm trucks in the Cleveland territory.

Harry E. Pence, of the Pence Automobile Company, recently purchased a 220-foot tract of land, where a temporary structure is to be built immediately for warehouse purposes.

Dr. Leon C. Long has secured the exclusive agency in Western Pennsylvania for the Babcock electric car of Buffalo, and will be located in the Rittenhouse Block on North Highland avenue, Pittsburg.

Kimmell Bros., Fourth and Spring streets, Columbus, O., have taken the Central Ohio agency for the Badger, manufactured at Columbus, Wis. The company has been handling the Speedwell and the Overland.

H. J. Schwartz, formerly a veterinary surgeon but more lately connected with the Atlanta branch of the White Co., has been engaged by C. H. Johnson, local agent for the Stevens-Duryea car, to manage the sales in this territory.

The Georgia Motor Car Company, of Atlanta, G. W. Hanson, president and manager, has absorbed the J. J. & J. L. McLendon Co., which sold the National car. Hereafter the Georgia Motor Car Company will sell the National car, in addition to the Benz, the Randolph truck, E-M-F, Flanders and Studebaker.

Coates-Goshen Company moved this week from 1619 Broadway to 1864 Broadway as was also the branch of the Dayton Airless Tire Company, which is jointly occupying the new store room.

The American Garage, of Indianapolis, has been chosen agent for the Royal Tourist in that city. Sales Manager H. M. Adams, of the Royal Tourist Car Company, Cleveland, announces that other agents will be chosen within a week.

Baron Van der Noot de Vrecken de Moorsal will represent the Krit Motor Car Company, of Detroit, at the Brussels Exposition. The Baron believes that there is a great future for low-priced American cars in Europe. He sails May 10.

David Davis, Jr., of Racine, Wis., has been appointed mechanical superintendent of the new gasoline and oil engine department of the J. I. Case Threshing Machine Company at Racine. Mr. Davis studied in German for three years after graduating from the University of Wisconsin.

Harry S. Moore has secured the agency for Northern Ohio for the Overland car. Mr. Moore has for some time past been distributor of the Stoddard-Dayton, National and Courier. The Overland has for two years been sold in Cleveland by the Overland Motor Car Company.

Harry J. Murch, Worcester, Mass., who has been agent of the Cadillac and Peerless automobiles, has purchased the interest of his partner, Charles E. Hidden, and will continue the business alone. Mr. Murch is to move his business June 1 from Central street to the new garage now being built on Main street, near Hermon.

The Morrison Motor Car Company, of Chicago, an Illinois corporation with $15,000 capital, has filed articles and a statement to do business in Wisconsin. The local interests are $2,500. The Morrison company handles the Pierce-Racine and has established Wisconsin sales headquarters in Milwaukee.

Among Pittsburg firms which have recently moved or enlarged their qnarters are the Pittsburg Automobile Company, which is now at 5909 Baum street, East End; the Pioneer Top Company, which has moved from Butler street to 5472 Penn avenue, and the Pittsburg Automobile Equipment Company, which has leased another big room on Baum street.

The New York Auto Supply Company, 1755 Broadway, New York City, have just secured the distributing agency for the Parry car, made by the Parry Automobile Company, Indianapolis, Ind. The territory comprises the Metropolitan district of New York below Albany, New Jersey and the lower half of Connecticut. The company will appoint agencies in all of the principal towns.

The Haynes Automobile Company, Minneapolis, has recently placed the Regal agency in Duluth and along the Iron Range with the Interstate Auto Company. P. J. McGuire, manager of the wholesale department for the Haynes company, made the arrangements.

AMONG THE GARAGES

President S. C. Tallman, of Auburn Automobile Club, Auburn, N. Y., and party in a Cadillac, returning from inspection of free bridge, erected for automobilists

R M. Owen, now vice-president Reo Motor Car Co., Lansing, Mich.

James P. Roodhouse, of Medora, Ill., is erecting a new garage.

Elyria Garage Company, of Elyria, O., is organizing an auto livery service for that city.

George Bettes will manage the new garage now being erected by C. D. Fenn at Antigo, Wis.

The Buckeye Garage & Sales Company has doubled its force of workmen as well as its floor space.

The Moyle garage building at 135-137 South State street, Salt Lake City, Utah, is nearing completion.

Metzger & Wells have a contract to build a $10,000 garage for Clarence A. Warden, in Haverford, Pa.

The Louisiana Motor Company has completed its garage near Baronne and Julia streets, New Orleans, La.

D. M. Huntington, of Grand Rapids, Wis., will open a garage. He has been conducting a repair shop for a year.

John W. Yule has opened a large garage and repair shop at 448 Broadway, Paterson, N. J., where he will handle the Pullman automobiles.

John Conway, T. W. Orbison and Dr. D. J. O'Connor, of Appleton, Wis., are the incorporators of the Appleton Garage Company. This company is building a large public garage in Appleton.

The Ohio Auto Sales Company has completed the work of remodeling the new garage and sales room on North Park street, near Goodale street, Columbus, O. The company handles the Ford in Central Ohio.

Stoll Brothers of Mt. Pulaski, Ill., are erecting a three-story brick building, the first floor of which will be used as an automobile garage, the second floor as a display and sales room and the third floor as a public dance and lodge hall.

J. Z. Wilklow, of Mishawaka, Ind., has commenced the erection of a one-story automobile garage on his property adjoining the new Mishawaka Hotel. The building will be 50 by 150 feet and will have conveniences for cars and repairs.

Schmidt & Herres, proprietors of the New London Iron Works, New London, Wis., are building a garage adjoining their shops. It will accommodate ten cars. The firm has taken the agency for the Overland and will make a feature of repairs.

The English Motor Car Company, of Massillon, O., was incorporated with a capital stock of $25,000 to engage in the general automobile and garage business by F. A. English, W. P. English, H. W. Loeffler, George W. Krotsch and Homer A. Hoftzer.

Dr. O. H. Thorpe and George A. Rauch, of Marysville, O., have sold their garage and repair business on Plum street to the Marysville Motor Car Co., recently organized by A. Earl Harvey and Walter M. Otte. Mr. Harvey will be general manager.

The Connellsville Garage Company has bought 65 by 165 feet on Apple avenue, Connellsville, Pa., and will build a $15,000 garage at once. The building will hold 40 cars and the company will start a repair and accessory business as well as a taxicab line in June.

The Fourth Street Auto Garage and salesroom, Barberton, O., was opened April 1 with Dr. G. E. Gardner, president, and E. G. Grady, secretary and general manager. They are agents for the Halladay and De Tamble cars in the counties of Summit, Medina and Wayne.

P. H. Haber, district agent for the Ford at Fond du Lac, Wis., has leased the Hass Garage, Macy street, between Forest avenue and Division street, and has taken possession at once. The name will be the Ford Garage and a general livery, repair and garage business will be carried on.

The Hoaglin Auto Company, of Oshkosh, Wis., is rushing work on a large new garage building in order that it may occupy the building by June 15. It is of fireproof construction, with brick walls and steel-trussed roof and will be ample to care for the immense transient garage trade developed by the Hoaglin interests during the last three or four years.

F. J. Briquelet, of Green Bay, Wis., has opened a garage at 215 Stuart street and will handle the Kline Kar. He is negotiating for several other lines. Mr. Briquelet was formerly associated with the Green Bay Motor Car Company, and is an expert mechanic. The present quarters are temporary and Mr. Briquelet plans to get a larger building before July 1.

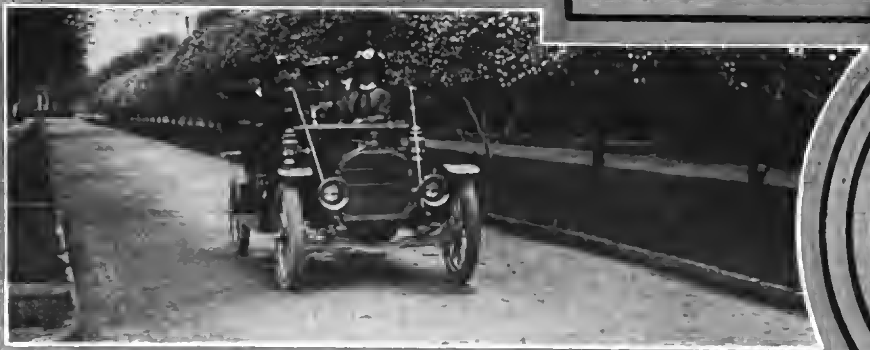
Personal Trade Mention

Herbert L. Shearer, for six years general manager of the plant of the Chicago Brass Works at Kenosha, Wis., has joined the central offices of the American Brass Company at Waterbury, Conn. George Allen, assistant manager at Kenosha, succeeds Mr. Shearer.

Peter S. Steenstrup, secretary and general manager of the Hyatt Roller Bearing Company, is enjoying a vacation. Mr. Steenstrup has been closely confined by business cares for several years and now he is going to spend several weeks resting. His rest will include mountain climbing and fishing in mountain streams of Oregon, the Columbia and the Pacific Ocean. Mrs. Steenstrup accompanies him.

J. B. Comstock, for six years with the Westinghouse Electric & Manufacturing Company at its East Pittsburg works, and for four years manager of its publication department and printing plant, severed his connections with that company in April to accept a similar position with the P. & F. Corbin Company, of New Britain, Conn. Prior to Mr. Comstock's connection with the Westinghouse Company, he filled the same position with the Corbin Company that he has recently been recalled to assume.

REALM OF THE MAKERS



View of one of Rochester's flower lined streets, the justly famous Oxford street, showing a Selden car among the magnolia trees

Geo. B. Selden, president of the Selden Motor Vehicle Company

The Ford Motor Company built and shipped out 1,035 cars between April 18 and 23, according to the records of that company.

The Fry Manufacturing Company, a concern organized to control the manufacture and sale of the Fry plug, is located at 1779 Broadway, New York City.

The Dayton Rubber Manufacturing Company has decided to increase its capital stock from $150,000 to $500,000 in order to provide for enlarged and augmented facilities for manufacture.

The Whitney Manufacturing Company plans for immediate construction of a five-story addition to the present big plant in Hartford, which is to be completed and ready for occupancy by October 1.

The Monitor Automobile Works have removed from Chicago to Janesville, Wis. The new plant has a floor space of 75,000 square feet, which is a material increase over what was formerly occupied.

The Billings & Spencer Company, of Hartford, has just completed a fully equipped emergency hospital in connection with the local plant, which is the outgrowth of a very modest beginning, a first aid cabinet.

The Rapid Motor Vehicle Company, of Pontiac, Mich., has purchased 16 acres of land adjacent to its present plant, and within two months, according to present plans, another big building will be completed and in running order.

The Castle Lamp Company of Amesbury, Mass., has purchased the assets of the Atwood-Castle Company and assumed its liabilities. The capitalization of the new concern is $300,000. F. E. Castle will have the management.

The Standard Specialty Company, of Cleveland, was incorporated with a capital of $10,000 to manufacture automobile accessories by Harry Dolitz, Cornelius Sheehan, Leo J. Kellosky, Charles M. Robertson and Louis M. Kleinhenz.

The Fal Motor Company of Chicago will be moved to Champaign, Ill. That city has agreed to give a site and erect the factory buildings to cover at least 100,000 square feet. The plant is expected to be in running order by Aug. 1.

The Pittsburg Motor Company, which manufactures the "Pittsburg Six" car at New Kensington, Pa., has bought from the Dawes Mfg. Co. of Braddock, Pa., a $25,000 site in Braddock, on which it will build a factory to employ 500 men.

The Warren Motor Car Company's new factory at Detroit will be completed by Jan. 1, 1911, if the plans of the construction, work out as expected. The first of the buildings 600 by 60 feet is approaching completion and the two others are progressing.

The Auto Motor Castings Company, of Cleveland, was incorporated with a capital of $50,000 to manufacture castings and other accessories for motor cars by Adelbert J. Miller, Charles H. Gunkleman, William Schofer, William Baisch and Elex L. Appleby.

With a factory 600 by 60 feet, three stories high, the Schacht Mfg. Co., of Cincinnati, is planning to enlarge its plant. The increased facilities will allow the company to treble its output in 1911. The capital stock of the company will be increased from $100,000 to $500,000.

The United Manufacturers will remove from their present quarters at Seventy-sixth street and Broadway to Motor Hall, 250 West Fifty-fourth street, where they will have offices covering 10,000 square feet of floor space. The change will be accomplished May 1.

The Auto Tire Re-enforcement Company of Auburn, Indiana, has reorganized and incorporated under the name of Double-Fabric Tire Company. A. L. Murray is president and W. H. Willenar is secretary and general manager. Tire re-enforcements and emergency tire repairs of various kinds will be manufactured in large quantities.

The Connecticut Shock Absorber Company, of Meriden, Conn., has purchased the tools, dies and stock of the Sager Shock Absorber Company. The former concern announces that the reason for the retirement of the Sager company is that its device was an infringement of the patents held by them.

Deliveries of the new 1910 type of six-cylinder, sixty-six horsepower cars of the Pierce Arrow Motor Car Company will begin in July. This will be in time for the latter part of the touring season and so that cars for fall touring in Europe may be available for those who intend to put them to such use.

Announcement is made by the E. R. Thomas Motor Company that the 1911 models of that company probably will be practically identical with those of the current year. While a definite decision has not yet been reached, the preliminary work indicates that any changes that may be made will be matters of detail rather than any radical departure in the construction.

The annual meeting and election of the Hartford Rubber Works Mutual Benefit Association resulted as follows: President, C. B. Whittlesey; vice-president, George Holloway; secretary, A. Elmer; treasurer, E. Fothergill. During the past three years there has been paid out in benefits to members $5,000 in cases of sickness and death. The association has a membership of 500.

A consolidation of the Standard Gauge Steel Company and the Standard Connecting Rod Company, of Beaver Falls, Pa., has been effected. The new corporation will be known as the Standard Gauge Steel Company. By the merger, facilities will be improved and capacity increased. The full lines made by each of the companies interested will be continued and others under consideration added. The management will be practically the same as it has been in both corporations.

NEWS IN GENERAL

Alexander Winton, president Winton Motor Carriage Co., Cleveland

Five ton load of orphans on a joy ride with Hal Sheridan at the wheel of White truck. A reminder of the Orphans' Day, which is soon to be celebrated

Paterson "30" cars will be sold in Brockton, Mass., by the Gay Automobile Company, 345 Warren avenue.

Hemery, Hanriot and Bruce-Brown will drive cars in the Grand Prize race on the Long Island Motor Parkway next fall.

Four Cleveland .factories have announced their intention of entering the Glidden tour. Two private entries are also promised.

The Miller Rubber Company, of Akron, Ohio, has increased its capital stock from $250,000 to $500,000. The company has doubled its capacity during the past year.

The Chicago Vulcanizing Company, of Chicago, has certified to a change of name to the Chicago Tire and Supply Company, and increase of directors from three to five.

The Ford Motor Company has beaten all records for shipments to Pittsburgh. Sixteen carloads of Model "T" Fords, including 48 autos, came in over the P. & L. E. Railway last Saturday.

The Locomobile Company of America, capitalized at $5,000,000 in New York, has been incorporated in the State of Illinois, with offices at Chicago. The capitalization in Illinois is $131,600.

The Selden car that will take part in the Brighton Beach 24-hour race has arrived at the track. The car is being given a special preparation under the guidance of George E. Mack, who will pilot it in the race.

The Washington Post Touring Test run from Washington to Richmond, Va., will be held May 27 to 31. Eleven entries to the event have been received so far and many more cars have been promised for the contest.

The New Jersey Automobile and Motor Club is seeking a location for its country branch. Officers and members have been engaged in seeking ideal sites, and it is reported that there have been found several that answer the requirements.

U-auto Varnish Company, of Cleveland, was incorporated with an authorized capital of $50,000, to manufacture an automobile varnish, by C. O. Perrin, A. B. Newland, H. L. Hullinger, H. W. Perrin and A. L. Talcott.

In the issue of THE AUTOMOBILE of April 7 reference is made to the "Apple Automobile Lighting Dynamo." While the system is made by the Apple Electric Company, of Dayton, Ohio, the trade name under which it is marketed is "Aplco."

The Cleveland Transmission Gear Company was incorporated with a capital stock of $5,000 to manufacture gear wheels for transmission of power in automobiles by R. H. Williams, Marion Kirkely, E. C. Kirkely, C. A. Myers and F. H. Hartman.

Cleveland Taxicab Company, of Cleveland, Ohio, was incorporated recently with a capital stock of $100,000 to operate a number of taxicabs. The incorporators were Charles S. Wachner, F. B. Williams, R. A. Wilbur, J. B. Graham and Benj. A. Gage.

More automobiles were sold in the United States during the thirty-one days of the month of March than in any corresponding period in the history of the automobile industry, according to reports received from many factories now working overtime.

W. R. Hines announces that he will locate a factory in or near Cleveland to manufacture a four-cylinder, two-cycle car designed by him. Mr. Hines has been experimenting with the Hines car for six years. He proposes to make 500 cars for 1911 delivery.

Rene M. Petard, manager of the European branch of the Mitchell-Lewis Motor Company at Paris, writes that the American idea in motor cars is making satisfactory progress abroad. M. Petard says that the success of the Mitchell car has been considerable.

The Goodrich Company, of Akron, O., recently started a road marker out from its factory. For the present, the roads around Cleveland, Akron and Canton will be marked. The marker will then start east from Chicago to Buffalo, thence through Albany to New York.

L. C. Alexander resigned from the Cleveland Warner Instrument office staff Saturday, to accept a position with the Willard Storage Battery Company. He will have charge of the automobile lighting department of the Chicago office. The Willard company is designing a miniature lighting system, the same as is used on trains, for automobiles. It will be on the market in a short time.

Spokane, Wash., is to have an agency for the Lozier, according to the announcement of the Metropolitan Motor Car Company, of that city. The territory includes Seattle and Portland. W. T. Sleddon, who formerly represented the Lozier in Seattle, has associated himself with the Metropolitan Company.

Sharp-Arrow cars are better known in racing than in trade circles, as this car, which is made in Trenton, N. J., has put up some fine performances over the Motor Parkway and the Riverhead courses. William Sharp, the builder, has completed plans for a special racing car which he intends to drive himself in the Grand Prize race on the Parkway next October.

Additional contracts have been placed by the Pierce-Arrow Motor Car Company, of Buffalo, with the Aberthaw Construction Company, of Boston, for the doubling of the size of the present office building of the former's Buffalo plant, for adding 200 feet to the motor testing building and the garage, and for building the truck assembly shop. The Aberthaw Company has just completed the large storage building and has partly completed the nickel-plating building of the plant.

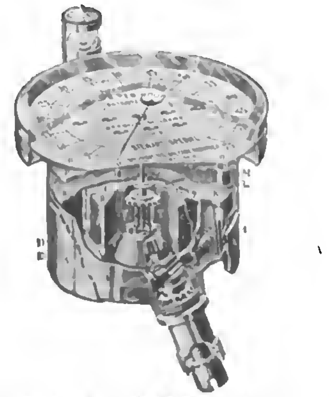
Kellogg electric motor-driven pump for use in private and public garages

STEWART OFFERS NEW SPEEDOMETER

The Stewart & Clark Mfg. Co., makers of the Stewart Speedometer, are now marketing a new type of speedometer, known as the "Stewart Special."

The illustration will make clear the design and function of the component parts. Multipolar induction is the actuating principle. AA is the containing cup or casing, one-piece drawn brass. U is the frame on which the parts are assembled. This frame is machined with integral sockets, bosses, shoulders, etc. B is the generator or rotor. It consists of a ring of nonferrous material, on which are mounted two permanent magnets CC, CC, of the closed-ring type, divided by an insulating plate. These magnets are accurately machined from imported tungsten steel, made to special analysis, the highest priced material obtainable from this purpose. They are hardened in a special furnace of our own design, are magnetized, aged and tested before assembling in the rotor. D is the spindle to which attaches the flexible shaft from the road-wheel connection. Formed integrally on the upper end of this shaft is the bevel pinion E, which revolves the rotor R through the medium of the internal bevel gear F. The central stud G on which the rotor B revolves is recessed to receive the cap and crown jewel bearing H. Stepped in this bearing is the tempered and highly polished pin I, secured to this pin is the disc JJ. This disc is made of an alloy metal, having a low resistance and is exceedingly light. The fixed plate KK serves as a support for the jewel guide L and one end of the restraining spring M, the other end of this spring being secured to the pin shaft I. To the upper end of the pin I is secured the indicating pointer N, which moves over the graduated scale OO. RR is the revolving field. TT is the rotor bearing of which F bevel gear is an integral part. Interposed between the plate KK and the dial scale OO is the odometer mechanism, of which PP is the lower plate. This odometer is driven from the spindle D by means of a hardened steel gear train, S being the drive connection.

Operation.—In operation, as the rotor is revolved, lines of force flowing from the magnets CC, CC through the disc JJ cause it to revolve in the same direction as the rotor. This tendency to revolve is resisted by the spring M and is exactly proportionate to the speed at which the rotor is revolved. By reason of this arrangement of the magnets a continuous torque or drag on the disc is maintained, insuring a steady, even movement to the indicating means. This feature is of the utmost importance and because of the exceedingly few inertia of the disc makes the indicator responsive to the minutest change in speed.



Stewart Special Speedometer

KELLOGG MOTOR-DRIVEN PUMP

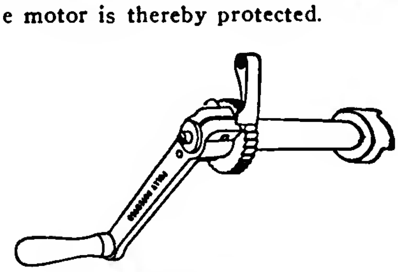
This pump is mounted on a heavy oak plank, which in turn is supported by substantial steel casters, so that it can be moved about. This pump entirely dispenses with the need of an air tank. The motor is of the Westinghouse make of 1/4 horsepower, for either direct or alternating current. It is attached to the pump by means of chain and sprocket. The pump is of four-cylinder 1-inch stroke, 1 1/2-inch bore, the engine base and crank case are of aluminum with the cylinder made of bronze, the pistons are leather and steel and are tested out for half a day at 500 r.p.m.

The company has tried in every way to burn down one of these leather washers, but has never been able to do so, and they fully guarantee them to stand up.

The cams are arranged on a quadrant in such a manner that one cylinder is always working. The pumps are all tested to 200 pounds and are guaranteed to deliver 120 pounds to the tire.

SIMPLE SAFETY STARTING CRANK

The illustration here presented of the Jones Safety Crank suggests simplicity, and the fact that there are but a few really sturdy parts in the makeup of this device should attract the notice of discriminating buyers. It will be observed that the safety crank is not keyed or fastened to the extension of the crankshaft as in ordinary cases. In this construction the end of the crank is split, and a clamping bolt, when it is fetched up, holds the jaws in tight relation with the bearing portion of the crank extension. The friction thus induced is sufficient to permit of cranking the motor. A steel pawl, which is fastened to the cross bar at the front end of the chassis frame, engages the teeth of a ratchet wheel, which is arranged to permit of cranking to the right in the process of starting the motor, but backward motion is snubbed by the pawl and ratchet and the autoist in the process of cranking the motor is thereby protected.



Jones Safety Starting Crank

THE AUTOMOBILE

Harrisburg Club Runs Fourth Annual Event

HARRISBURG, with its fourth annual roadability run, made a dashing start on the morning of May 10. It is for three days. The itinerary of the run, starting from Harrisburg, is Philadelphia, Atlantic City, Wildwood, and return to the place from whence they came. The run is under the auspices of the Motor Club of Harrisburg, is under the rules (for 1910), and is sanctioned by the "Contest Board," of which S. M. Butler is chairman. The officials of the Harrisburg club who are responsible for the run made every necessary preparation and the reward is just within their grasp; there is every indication that the end to-night will be fine.

The distance from Harrisburg to Atlantic City is 168 miles, which represented the first day's work, and the arrival there was in due season, heralded by all the motorists of that popular seaside resort. It was a heavy day, from the weather point of view; rain fell for a considerable portion of the time, but despite this rather unpleasant phase of the situation, the run was hugely enjoyed, and it was to the credit of the contesting automobiles that there were no serious incidents to mar the day.

ATLANTIC CITY, May 9—Forty automobiles made the journey from Harrisburg, and while many of them were entered by maker's agencies, the fact remains that there was a goodly sprinkling of owners in the merry throng. There were a thousand incidents which happened along the way to upset the monotony of the weather, and citizens along the line were as much interested as the contestants themselves, if appearances count for anything.

In Pennsylvania the roads were extremely good, excepting for a stretch of bad going between Reading and Pottstown. This part of the way was in mighty contrast with the "pikes" in Pennsylvania and New Jersey; they were the wonder and the source of continual admiration on the part of such contestants as were strangers to this state. Despite the rain and the general inclemency of weather, the roads in New Jersey were hard and dry; the rain tumbled down and rolled off and away through provided channels as water from a duck's back; the automobiles passed along and on just as if the sun was shining all the time, and the autoists in their rain togs enjoyed every moment of it with an added interest for every foot.

The story of cars dropping out of the perfect score ranks in the first day was looked for, and in the maker's class four had to surrender this coveted honor for one day. On the second day's run six more were disabled in one manner or another, so that by the end of the second day only eleven of the original twenty-one remained with clean scores. On the opening day the cars made the pace as fast as possible, and some suffered because of this. The Mitchell was given fifteen points for having to take on gasoline and water outside of the noon and night controls. This car withdrew on the second day, but will complete the circuit as a non-contestant. One of the Kline Kars, driven by Sieg, ran out of gasoline a short distance out of Norristown and received 27 points. The driver, A. D. Rea, had to go some distance to secure gasoline, and was penalized for the filling and also for the time the car was late in reaching its controls.

On the second day more penalties were added. The Mitchell six which received some penalties on the opening day was withdrawn. The Regal received six points for carbureter adjustment. The Kline Kar, driven by McCulla, was penalized three points for adding oil between noon and night controls. Nine points were given the Enger car for tightening nuts that worked loose on the gear set. The Pullman, driven by Ickes, received fifteen points for putting on a new fan belt. Herb Bitner, driving a Pullman, was given one point for carbureter adjustment.

To date the penalties have been more for adjustments than for defects of construction, there being a big loss in points through dirty gasoline. It is expected that to-morrow's run of nearly two hundred miles will add to the number of cars that have been penalized, so that by the time all cars have taken the final outdoor test and technical inspection there will be few of the present eleven perfect scores remaining. Compared with past seasons, it is very remarkable how few of the cars have lost points through broken springs, frames or wheels, which is to an extent accounted for by the smooth roads.

The list of private owners competing is:

Maxwell, H. C. Wright; Mitchell, J. W. Shaffer; Maxwell, D. G. Bowman; Buick, E. K. Frazer; Ford six, W. G. Starry; Maxwell, F. H. Bomgarden; Cadillac, J. E. Dare; Buick, M. H. Baker; Kline Kar, M. E. Brightbill; Kline Kar, M. B. Cumbler; Buick, Donald McCaskey; Cadillac, W. H. Riggle; Maxwell, S. F. Metzer; Rambler, J. A. W. Brubaker; E. M. F., R. H. Forney; Pullman, T. O'Connor; Franklin, Geo. Karlavan; Pullman, J. L. L. Kuhn.

In this amateur party are passengers in most of the cars, and they all run on a 17-mile schedule in Pennsylvania and a 20-mile pace in New Jersey. They start each morning immediately after the makers' cars have been checked out, and are required to check in at all of the checking stations.

WILDWOOD, N. J., May 10—The second day of the three-day fourth annual tour of the Harrisburg Motor club ended here to-night, fine weather having followed the tourists except for a few hours after the start from Harrisburg Monday morning. It is rarely if ever there has been in America a tour by a local club which has created more interest throughout the territory traversed than the present one. This widespread interest is due primarily to the excellent publicity campaign throughout the territory covered by the run and also because of the local interest worked up in the different towns passed through by the promoter. In all twenty prizes are offered, two special prizes and eighteen trophies and of these eighteen trophies four were donated by the city of Bridgeton, three by the city of Millville, two by the town of Salem, six by Reading and one by Wildwood. These trophies, as well as the two given by Harrisburg have stirred up widespread interest. Another factor in stimulating interest in the run is the big list of private owners or amateurs as they might be called. There are 18 amateur or private owners in the run and 21 cars entered by manufacturers so that this field together with official cars makes a grand total of forty-nine cars or more than were in the Glidden tour of last year. This big entry list, which is representative of a goodly number of cars, taken in connection with the miles of roads that have been dragged and specially prepared for the tour, is conclusive proof that the Harrisburg club has the co-operation of the district.

Score for the First Two Days of Run.

Atlanta's Epochal

ATLANTA, May 7—The three-day race-meet which ended here to-night, although not a success from the view-point of number of entries or attendance, was, nevertheless, most interesting, as many of the races were closely contested and not any car had a certainty of winning everything in its class. The whole attendance on the three days did not total over 20,000, whereas the grand stand and bleachers will accommodate over double that number. In all fourteen cars of different makes competed in the program; the speed merchants being the Marmon six with cylinders 4½ by 5 inches, the Fiat 90 with cylinders 130 by 190 millimeters and with double-intake and exhaust valves, and the American roadster with cylinders 5¾ bore and 5½-inch stroke.

In the meet only one record was broken, namely, the 20-mile event stock chassis, in the 451-600 cubic inch class. De Palma driving a Fiat 60 with cylinders 140 by 130 millimeters, clipped nearly 2 seconds off the mark.

In many of the other races the times made were very close to the old records, but the rough condition of the track made it almost impossible to equal the old marks.

The cars entered in the various events were as follows:

	Bore	Stroke	No. Cyls.	Piston Dis.	Weight
American	5¾	5½	4	571.3	2,850
Buick	3¾	3¾	4	....	1,404
Cole	4	4	4	201.1	1,728
E-M-F	4	4½	4	226.2	1,565
Fiat	140	130	4	....	2,748
Fiat	130	190	4	....	....
Firestone	4	4	4	201.1	1,620
Knox	5	4¾	4	373.	2,398
Marmon	4½	4½	4	286.3	2,205
Marmon	4½	5	4	318.1	3,254
Marmon	4½	5	6	477.1	....

Good Start for Around New Jersey Run

UNDER weather conditions that could hardly have been improved upon, the Around New Jersey Reliability Run, under the auspices of the Motor Contest Association, started on schedule time Tuesday morning with thirty-one cars on the line. The route, which was to Atlantic City and return, 157.9 miles on the out-trip and 155.1 on the return, was arranged over a variety of roads to test the touring efficiency of the cars. The roads were in excellent shape and there was nothing to mar the comfort of the drivers.

The starters included:

Class 1A—$800 and under.

Car.	Entrant.	Driver.
Hupmobile	F. L. C. Martin Auto Co.	Elmer D. Cutting
Hupmobile	F. L. C. Martin Auto Co.	R. E. Gillam

Class 3A—$1,201 to $1,600.

Car.	Entrant.	Driver.
Cole "30"	Colt-Stratton Co.	F. Warmington
Regal	Regal-Detroit Auto Co.	W. H. Bowers
Overland	Essex Overland Co.	George L. Riess
Maxwell	L. M. Bradley	L. M. Bradley
Buick	Buick Motor Co.	W. C. Davenport
Maxwell	J. W. Mason	Charles Schaffer

Class 4A—$1,600 to $2,000.

Car.	Entrant.	Driver.
Pierce-Racine	G. M. Merrill	Lewis Strang
Auburn	LaDue & Carmer	Herbert F. Earle
Franklin	Franklin Auto Co.	Paul Harvey
Chalmers	C. H. Page & Co.	Joseph Bell
Koehler	Dr. Alex Dallas	J. J. Bryer
Buick	Buick Motor Co.	Paul Hines
Marion	Charles E. Riess	W. F. Bradley
Cadillac	Detroit-Cadillac Co.	N. L. Lichtenberg
Cadillac	Charles M. Welsh	L. R. Burne
Midland	Midland New York Co.	Leo Anderson

Class 5A—$2,001 to $3,000.

Car.	Entrant.	Driver.
Stoddard-Dayton	Atlantic Motor Car Co.	R. Newton
National	Poertner Motor Car Co.	W. C. Poertner
Croxton-Keeton	Croxton-Keeton M. C. Co.	O. P. Bernhard
Mitchell	Mitchell Motor Car Co.	O. R. Delamater
Mora	Mora Motor Car Co.	Charles Hinman
Mercer	Floy & Clark	H. S. Clark
Mercer	Added Starter	Joe Trehou

Class 6A—$3,001 to $4,000.

Car.	Entrant.	Driver.

Welch-Detroit	Buick Motor Co.	Robert M. Flagg
Matheson	Matheson Auto Co.	Neil Whalen
Haynes	Walter Shuttleworth	W. Shuttleworth

Class 7A—$4,001 and over.

Car.	Entrant.	Driver.
Zust	T. J. Gerehart	Joseph Kingsland
Zust	American Zust Motor Co.	V. P. Pisani

The American and Stearns entries and one Maxwell car that was eligible, did not start and the Glide car was disqualified before the start owing to the lack of condition of the driver.

The start was from Fifty-seventh street and Broadway at 7.30 o'clock, thence to the Twenty-third Street Ferry and the public square in Jersey City, where the cars were sent away on their course.

The following is a list of the officials who had charge of the run: A. H. Whiting, referee; J. B. Ireland, pacemaker; Raymond Beck, pilot; J. M. Carples, chief observer; A. N. Jervis and E. F. Korbel, checkers, and A. L. McMurtry, Edward Johnson and C. H. Martin, technical committee. W. J. Morgan, president of the Motor Contest Association, was there.

Headed by the Franklin truck, which carried the baggage of the participants in the tour, the column reached Lakewood, N. J., Tuesday noon. In the afternoon the tourists proceeded to Atlantic City which was reached without extraordinary incident. Thirty out of the 31 starters arrived at the night control. Wednesday morning the return trip was started and shortly after 4:30 o'clock the contestants began to arrive in Jersey City.

The same excellent checking arrangements were in force at the finish as had obtained at the start, and with a minimum of confusion the wearied drivers shot their cars over the line.

The last leg of the run was over roads not quite up to the standard of Jersey highways and several of the contestants were covered with dust as the cars finished. The winners in each of the classes will be awarded gold medals; the seconds, silver, and those who finish third will get bronze decorations.

How the Cars Looked When Lined Up in Newark

New National Torpedo Body Attracted Much Attention

Mora Light Four-Cylinder, Driven by Hinman

—and not so long ago either—when au-
:w Jersey included a number of extra-
gles that should have no place in the
: was a notorious fact that the automo-
ıplated a tour always found it conven-
$2-bills, with which to smooth out the
'er-officiousness and over-zealousness on
y peace officers. "Jersey Justice" had a
ɔration was deserved.
Automobile and Motor Club never did
ct that unjust, annoying and almost in-

tolerable condition it performed a service that entitles it to a warm place in the hearts of motordom. It did a great work in this matter and it did it so thoroughly that the necessity for the roll of $2-bills has been obviated and a tourist can enjoy the magnificent roads and scenery of New Jersey without hindrance if he simply observes the law of the land.

This has been accomplished through the activity of the giant organization which has its headquarters in Newark. The club is said to be the largest and most powerful in the United States. It was founded June 1, 1903, with twenty-nine members. Two years ago it moved into its present quarters at East Park street and Park place, Newark, and to-day it has 2,087 members, including the leading citizens of the state.

The club takes a strong position in every line of automobile activity. In the first place it offers legal protection against persecution and unjust suits instituted against members. The club takes up the legal battles without charge and the records show that it has met with extraordinary success. While the casual reader might imagine that this feature of the work would seem to encourage reckless handling of automobiles under the protection of the organization, the very opposite is the truth.

The felicitous outcome of the club's campaign against "over-officiousness" on the part of certain country constables and justices, which rendered necessary the $2-bill bankroll as a condition precedent to any kind of an extended tour, was the result of a plan worked out by A. B. Le Massena, secretary of the organization. When the "over-officiousness" was at its height, the club organized a motor-cycle squad consisting of some ten or a dozen members and when an unwary tourist was about to trundle into a speed trap, at the end of which was a log chain and a group of "needy" officers, a motor-cycle emissary from the club would dart out of a crossroad and halt the automobile. Then the sentry would hand the occupants of the car a card that read like this:

> **Warning!**
>
> **Speed Trap Ahead**
>
> You are warned that a speed trap exists on this road just ahead. Go very slow until you pass the danger point.
>
> This Warning Is Issued by the
>
> **New Jersey Automobile and Motor Club**

On the back of the card is printed a blank application for membership and not a few of the enthusiastic members of the club were first introduced to it through this medium.

If the motorist happened to run foul of the "authorities" he was instructed to take complete data of the proceedings. This consisted of the name and address of the member; the date; the name of the justice and his location; names of witnesses, and the amount of the fine. He was also instructed to take a receipt for the fine, if one was levied.

This proved most disconcerting, as it gave a definite line upon the money paid in and afforded a basis for appeal that cut down revenues with a broad sweep. One illuminative fact has developed since the club commenced its campaign. The amount of fines turned into the state treasury has increased, while the club members say that prosecutions have been cut down over half.

The club gives from six to ten runs and tours during each year and at least one real contest. The runs are all strictly for the pleasure and benefit of the members, while the contest brings out manufacturers' cars in large numbers. This year the event will start early in the morning of June 11. Four classes of cars have been provided for and strict technical rules will be observed. Class A includes cars listed at $950 and less. Class B includes cars listed between $951 and $1,500. Class C includes cars listed between $1,501 and $2,500. Class D includes cars listed at $2,501 and over.

The course, which has been laid out to cover all kinds of roads and conditions from the steep hill and narrow path to the broad and smooth highways of the level plains, is 145.3 miles long. Twice around is the distance of the race and the small cars are required to complete the course in fifteen and a half hours, while the other cars must make it in an hour less. A liberal entry list is expected as soon as the blanks are distributed.

Silver cups for the best scores in each class have been provided. The entrance fee is $15.

The newest project of the club is the acquisition of a country branch. Much care was exercised in the making the choice of a location and the decision recently has been announced that the selection is a five-acre plot lying near Butler, N. J.

It is about twenty-five miles out from Newark on the old Pompton turnpike. The route is via a stone road all the way and leads along the scenic Pequanock river road. The way from the Newark headquarters to Butler is through Montclair. Singac, Mountain View, Pompton to Butler. The branch clubhouse site is in the foothills, 700 feet above sea level. The house stands on a bluff, fronting upon a private lake of sixty acres extent. This lake is stocked with game fish and is strictly preserved. It is called Apshawa Lake and is one of the most beautiful spots in that section of the country. A bungalow for the benefit of members who wish to enjoy the fishing is being built, and many improvements in the present plant are being made.

There is a spacious old mansion now upon the property, but the club intends to build an addition that will double its size.

The plans contemplate a clubhouse two and a half stories high with a basement. There will be a chauffeurs' dining-room and quarters and on the main floor a restaurant to seat 60 persons. The upper floors will contain a dozen bedrooms, equipped with every convenience. Between the addition and the present building the club will build a pergola and corridors connecting it with the old building and a wide veranda will surround the whole.

The townhouse of the club, at 64 Park place, is an impressive building. It is three stories and basement and when the club first occupied it it seemed as if it would be large enough for all time. But in two years the New Jersey Automobile and Motor Club has grown so swiftly that the big house is no longer adequate for its purposes. This year the club will stay in the present quarters, but next year a permanent location is to be purchased.

The club has a lot of attractions and conveniences. It has a restaurant and grill-room that rival the best in Newark in the matter of cuisine and service and is equipped with billiard and pool tables and rooms where bridge and other games may be enjoyed, beside a dozen other details of service to its members.

In a financial way the club is in excellent shape, owing nothing and possessing a comfortable bank balance. Its secretary, Mr. Le Massena, is a business man of high ability and he has the confidence of his officers and governors as well as the general club membership.

The annual meeting was held very recently and the following officers were chosen: President, Clarence H. Bissell; vice-president, H. D. Bowman; treasurer, George H. Simonds, and secretary, A. B. Le Massena. The board of trustees includes besides the above: W. C. Crosby, Guido O. Groebe, Dr. F. B. Meeker, J. B. Scarlett, Lewis Strauss, Paul E. Heller and J. L. Adams, Jr.

South Shows How Roadbuilding Is Done There

THE problem of the use of convict labor in building the good roads of our nation is fast assuming an aspect of particular importance, and is being given the serious consideration of the chief executives and other thinking men in the several States interested in this movement. At the present time there are a number of the commonwealths in the Southern sections of this country which have shown a commendable spirit in having their prisoners do a work which benefits the entire State rather than spend their time in idleness or in a series of prison occupations which simply pay for their own expenses and do not benefit any one outside.

The importance of the good-roads movement, with its lessened cost of transportation, and its increase of automobile touring with the accompanying influx of money, is fast being realized by many of the States and the developments in this line are of particular interest. Louisiana, sometimes supposed to be a State which was not making any special efforts in the direction of progress, is now showing itself to be wide-awake and the movement which has been started there for good roads, with the support of some of its most influential men, will probably do more to open up that section of the South than anything that has happened in recent years.

The history of this movement for good roads is an interesting one inasmuch as it has taken two and a half years to bring these plans to a culmination and to show actual progress in the work. New Orleans as a city is a great surprise to Northerners, for its reputation of quaintness, of old style, and appearance of a past age, are certainly misnomers.

In the matter of its fine streets, large substantial buildings, and beautiful residences, it is not surpassed by any Northern municipality, and it is, perhaps, this prevailing spirit of progress which has influenced the promotion of the Motor League of Louisiana, a body which is composed of well-known and influential citizens, with a steadily growing membership. The necessity for good roads in the State was at once appreciated upon the formation of this organization and just two and a half years ago the campaign for improved highways was begun by P. M. Milner, the president, and Victor Aschaffenberg, secretary, both of them enthusiastic automobilists.

It was figured that $30,000 would be necessary to complete the first road in order to show the advantage of the improved service if extended throughout the State, and it was decided to select a certain old trail, built eighty years ago, leading to Chef Menteur, which would give a distance of twenty-three miles and would open up a country renowned for its fishing and hunting, allowing the trip to be made in a couple of hours by motor, to grounds which could only be reached by train or boat at certain times of day and in several hours. When this route was announced, the failure of the plan was at once predicted because the road was at that time absolutely impassable and it lay through a country of luxurious Southern foliage, where splendid live oak trees and hanging Spanish moss formed an archway overhead. Chef Menteur has a splendid natural harbor and it was formerly open to the Gulf of Mexico, but the Louisville and Nashville Railroad fifty years ago built tracks across the outlet compelling all vessels to go to Rigolets. Recently the United States Government Engineers have pointedly recommended that this railroad build a drawbridge, thereby giving a coast outlet to Chef Menteur for yachts and lumber and oyster schooners, and making a road thirty miles shorter through Lake Borne, from the Gulf into the Mississippi at New Orleans.

It was soon found that $30,000 could not be raised among the motorists whose interest could be enlisted, but this did not deter the ideas of the moving spirits of the new club, and seven of the men contributed $100 each for a survey of this road to be made through the City Engineer, W. J. Hardee. The survey was reported most favorably and the scheme was pronounced thoroughly practicable so that the movement was started in earnest. The first assistance was received from Mayor Martin Behrmann and the City Council, who at one night meeting introduced an ordinance, passed it unanimously, and appropriated $2,000 for experimentation, as to the best type of road surface. The Mayor gave his personal assurance that if the road was constructed it would be maintained by the city, being within the city limits. It might be stated here that New Orleans has the largest area of any city in the country, having 265 square miles within its boundaries, although only seventy square miles are populated. Of the twenty-three miles to Chef Menteur, only eighteen had to be constructed by the League inasmuch as the remainder was composed of city asphalt streets and a series of splendid shell highways in the suburbs.

About this time Governor Sanders, himself a good-roads enthusiast, devised a new scheme of using the convict labor in the open country rather than in the closed prisons or on the state farms. The failure of other cities in this particular was assigned to the fact that they farmed the criminals out and there were many serious complaints against the treatment of the latter, who were entitled to at least human consideration, so this up-to-date chief executive arranged a new plan. In Louisiana, the Governor has the right to furnish convicts for other work than on the cotton and sugar plantations of the State, as long as they are not leased. On these farms they have paid their own expenses, but at times there are more convicts than necessary, so in conjunction with the automobilists it was arranged by the State authorities late last Fall to organize camps of twenty-four negro convicts each for work on the roads. The white prisoners are used in the commissary department, and all of the men are watched constantly.

The Motor League of Louisiana agreed to take the first camps upon the following basis: To pay for all food, the salary of the armed guards, one-half the cost of the resident engineer, and the fee of the visiting physician who inspects the negroes three times a week, and the state agreed to furnish the camp equipment, consisting of a commissary wagon, one or two berth wagons, a portable screened jail, tents, etc.

On the twenty-first of February of this year the actual work on this roadway was started and the first formal inspection took place on April 17. In just about two months, working six days a week, the convicts have dug ditches, and graded and crowned roads for a distance of about four miles, from Gentilly road to Michaud station, and they have given positive assurance of the success of this great undertaking. It is estimated that it will take eight months longer before the preliminary, or comparatively rough work, is completed, and perhaps, within this time they may have an opportunity of putting on the top coat of heavy gravel covered with a dressing of asphaltum oil.

Upon this pleasant Sunday in April there congregated at a prominent point in New Orleans, a party of particularly distinguished persons, who arranged to look over the ground thoroughly, and to give especial attention to the conditions of the convict camp at Lee Station. A number of local motorists volunteered their services to carry the State and City officials to the scene of action, and the factory representatives of the Premier Motor Mfg. Co., who were at that time in the city, placed the big six-cylinder Wistaria Premier touring car, which has been used by the Imperial Potentate of the Shriners during the convention, at the disposal of Governor J. Y. Sanders, ex-Governor W. W. Heard, president of the Penitentiary Board of Control, and Mayor Behrmann. E. B. Williams in a Premier carried E. E. Sykes and the newspaper men; A. J. Stallings in a Locomobile carried J. J. Frawley, president of the City Council, and James Reynolds, Chief of Detectives; C. H. Ellis, president of the United Fruit Company in his Peerless was accompanied by Henry Krohn and Captain John Deibert, a wealthy lumberman; and Palmer Abbott in his Packard carried Mr. Milner, Mr. Aschaffenberg, Joseph Schwartz and G. F. Boudereaux. Others in the party were E. B. Williams, E. J. Roderigue, M. B. Fletcher of the Premier Co., and the writer.

This party was driven through the beautiful suburbs of the city and out into the bracing morning air, through groups of picturesque negro shanties, and bits of woods and fig orchards, to the country of the live oak and the real Southern scenery. It was interesting to the Northerners in the party to travel over several miles of shell roadway which are as hard and well kept as anything in Jersey, before coming to the new operations. They were then taken over four miles of recently constructed surface at a lively clip, and the new road appeared to be particularly solid and well drained. But beyond the point to which the improvements have at present reached there are miles where an automobile would be useless, and indeed one of the cars sank so deeply as to necessitate taking it out. This was just an apt illustration of the "before and after treatment" and showed the necessity of the enthusiasm now abounding. The Motor League has paid for the plows, scrapers, and other machinery, and a large number of the members have contributed between $100 and $200 each to assure the furtherance of the operations. Their success is leading other parishes to inquire about the movement and Governor Sanders has assured them that any one in the State may receive organized camps of convict laborers.

The plans for the future call for a belt road around the entire city, with a number of well-prepared feeders into the interior. As yet no definite ideas have been formulated as to a series of roads which would lead from New Orleans, the principal city of the State, to the large cities in the neighboring commonwealths, such as Atlanta, Mobile, Memphis, and Texas points. It is very probable that this will be taken up as soon as the present situation is shown to be a phenomenal success and one which bids fair to give more life and wealth to New Orleans than any single factor in recent years.

Start of Governor and Party to Inspect Roads in a Premier

Beyond the Road Improvement, Even the Edges are Dangerous

Standard Process of Finishing Automobiles

By M. C. Hillick

FIRST let us consider the oil and lead system which, since the early days, has been the premier system in all departments of painting where quality is a factor of importance, referring to wood bodies only.

Sand and clean up the surface. Into pure raw linseed oil stir enough keg white lead, ground in oil, to stain the oil somewhat and check the excessive penetrating property of the oil. Whip the lead into a batter before adding it to the oil. Lay coat on thin and smooth.

Use a purchased ready-mixed roughstuff, or, if preferred, a shop-mixed one, adding to either, for this first coat, a small quantity of keg lead to give the material greater density and compactness of texture. If shop mixed take equal parts, by weight, of keg lead, oil ground, and any good American filler, beating the two thoroughly together to a stiff paste, in equal quantities of coach japan and rubbing varnish, then thinning to a proper brushing consistency with turpentine. With a good chisel-pointed brush apply a coat of this filler.

The Fourth Day Brings Work to Do

Go over the surface carefully and putty up all defects with a hard-drying automobile putty made as follows: Dry white lead, three parts; finely bolted whiting, one part. Mix in equal parts of coach japan and quick-rubbing varnish to the proper working consistency.

Apply second coat of roughstuff, laying material off at right angles to the first coat. If the ready-mixed roughstuff is used omit the extra allowance of white lead mentioned in connection with the first coat.

Sixth, Seventh and Eighth Day's Demands

Apply one coat of roughstuff each day, changing the color of the last coat by adding either a little dry Indian red. or yellow ochre, thus serving to give the workman a guide coat to rub by.

Using plenty of water, with blocks of artificial rubbing stone, which in composition run from coarse to fine, using the coarse stone first and the fine to finish with, block down the surface to a smooth level condition. Wash the surface thoroughly.

Sandpaper with No. 0 paper to loosen up possible accumulated substances. Dust off and apply one coat of color. P. M.—Apply a coat of color-and-varnish.

With a thin piece of perforated felt, wet, and dipped in pumice-stone flour, go lightly over the surface, "killing" the gloss uniformly. Wash off and apply a coat of elastic rubbing varnish containing just a pinch of the body color to preserve the original purity of it. In case any of the lakes or the transparent colors used, as a rule, in the form of glaze colors, are employed, it will be necessary to change the system to the extent of introducing a preparation coat of color and using the glaze coats over this. Rub the surface with water and pumice-stone flour, applying a firm, uniform surfacing, wash up, and stripe, and apply other ornamental work desired.

Apply Varnish on the Sixteenth Day

Wash up and apply a second coat of elastic rubbing varnish.

With water and pumice-stone flour rub the varnish all over thoroughly and uniformly wash up perfectly clean and flow the surface with a pale elastic finishing varnish of the best grade.

During this time the chassis should be painted in a manner to correspond to the body and brought to a finish.

There are a number of patent surfacing systems being marketed by paint and varnish manufacturers which may, without disadvantage, be substituted for the lead-and-oil system above outlined, the first or priming coat of these systems being a transparent medium, and in some cases to be wiped off with soft pieces of cloth after being brushed on. The time limit does not, however, vary greatly from that above described for the lead and oil, when first-class work is in order.

By applying roughstuff, one coat in the morning and one in the afternoon, making two coats per day take the place of one, and omitting one coat of rubbing varnish about three days in the schedule may be saved, thus getting the finish within 16 days.

Rapid System of Finishing Is Cheaper

The demand for rapid systems of painting both metal and wood bodies has developed to such an extent of late that there have been evolved methods with which to meet this demand.

For metal.—Clean surface thoroughly. Apply either a patent metal primer of which there are plenty, or one made of one part raw linseed oil and three parts turpentine with a stain of lead in it.

Mix dry white lead, three parts, and best bolted whiting, one part, in equal parts of coach japan and rubbing varnish, (elastic) adding a teaspoonful of raw linseed oil to each pound of the mixture. Work this down to a condition to smooth out under the blade of a broad, half-elastic putty knife, and apply to the surface with the knife, drawing the pigment out thin, smooth, and in shape to sandpaper to a good surface with a minimum amount of work. Color this surface to meet any shade desired for the final body color.

Sandpaper on the Third Day in the Morning

Sandpaper surface thoroughly, first with No. 1 sandpaper, second and finally with No. 0 to fetch out the fineness. Same day, P. M.—Dust off and apply one coat of the regular body color to be used, if such color is known as an opaque color. Lay on a coat of ground work color, if a transparent or glazing color is called for. In mixing this first coat of color use one part raw linseed oil to five parts turpentine.

Apply coat color-and-varnish or coat of glaze.

Rub lightly with a roll of broadcloth dipped in water and in No. 00 pulverized pumice stone to deaden the gloss and knock down any dirt atoms. Same day, P. M.—Apply coat of elastic-rubbing varnish into which a bit of the flat color has been thoroughly stirred. Again, with pads of felt dipped in water and No. 00 pulverized pumice stone rub the varnish carefully, clean up, and apply any necessary striping.

Color Is Again Applied on Eighth Day

Apply coat of clear elastic rubbing varnish.

Again rub as above with water and pulverized pumice stone, wash up, and finish with a rich, full body-finishing varnish.

During this course of painting and finishing the body, the chassis should be cleaned, painted and finished to match the body.

For wood-body surfaces this same rapid system may be employed, except that in the priming six parts raw linseed oil and two parts turpentine be used. All other operations to be carried out as in case of metal surfaces. By substituting quick-rubbing varnish for the elastic the system may be abbreviated to the extent of at least two days.

The chassis should in painting always be brought along with the body and given every necessary attention. It should have the same primer, and above this should be laid at least two good coats of lead, or, as the case may be, patent surfacer, each coat being perfectly sandpapered and made fairly glass-smooth, and puttied wherever needed. Then in order come the color or ground-work coat, color-and-varnish or glaze coat, then a light rubbing with water and pumice-stone flour, striping, and one coat clear rubbing varnish. In due season surface this coat down with water and pumice-stone flour, wash clean, and finish.

Thus is the automobile painted and finished with due regard for harmony and a proper balance of all the parts.

1910 Touring Information for Autoists

PERHAPS, in time, the type of dictionary which will be accepted as autboritative will give a comprehensive definition of the word "touring." It is not so long ago that the idea of touring was confined to the process of racing around the country, violating speed laws and ruffling the temper of the natives, besides tearing up the roadbed and doing all the other things which made it utterly impossible to know anything about the locality througb which such swaths were cut, and of pleasure it was frequently confined to a restful sojourn in the ward of convenient hospitals.

Familiarity is said to breed contempt, and the time arrived in the career of the sensible autoist when his contempt for mere speeding is best expressed by the leisurely fashion in which he prefers to tour when the spirit moves, and this leisure idea is quite independent of the ability of the car, which in nine cases out of ten will do better than a mile-a-minute pace. Touring for pleasure, under the circumstances, must take into account a certain familiarity with the scenery and the surroundings, and the problem which will confront the autoist of acumen in the near future will be solved when he finds an accurate source of information, historical, geographical and topographical, beyond the dream of the autoist of yesterday who merely wanted to know how far it was from this place to that, and if he could get through without having to hire a horse.

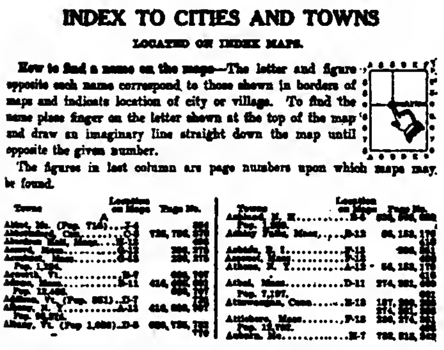

Fig. 1—Facsimile of beginning of index to cities and towns with means for locating any given place on the guide map

It would seem that the Official Automobile Blue Book for 1910 is designated to meet the needs of the autoist who prefers to tour; in fact, it gives, as a primary consideration, an index, which is reproduced in facsimile (just a small portion to illustrate tbe idea) in Fig. 1, and a diagram is there presented, by means of whicb, if the directions are followed, names of towns along the respective routes may be located on the "key map," a portion of which is given in facsimile in Fig. 3. This map shows all the routes which were definitely surveyed by the topographical engineers employed in the building of the Blue Book, and each route is numbered.

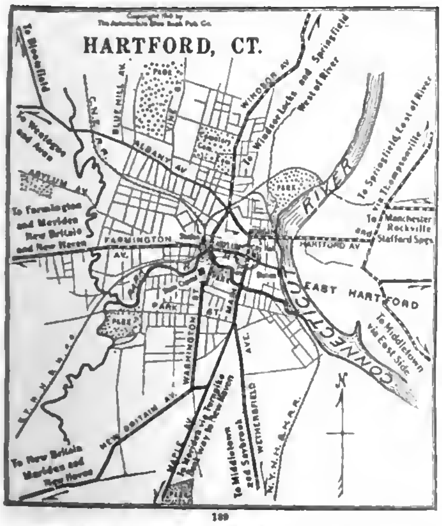

Fig. 2—Map of surveyed routes out of Hartford, Conn., which is one of a series of maps shown in Volume II of the New England Section of the Blue Book

With a view to a better understanding of the makeup of this comprehensive work, an illustration of its workings will be given as follows: Turning to page 189, the route map, as shown in Fig. 2, will be found, which map is of routes 161 to 180 inclusive. In order to make further progress in the explanation of the workings of this plan, one route will have to be selected, and for this purpose route 162 is given in facsimile one-half size, as shown in Fig. 4. The key map (Fig. 3) then, in conjunction with the index (Fig. 1), enables the autoist to find any desired route which has been mapped out in the book. With the key map, after having picked out the route number, it is only necessary to turn to the route map, which will be known by the number taken from the key map, and then to the route text, which also carries the same number.

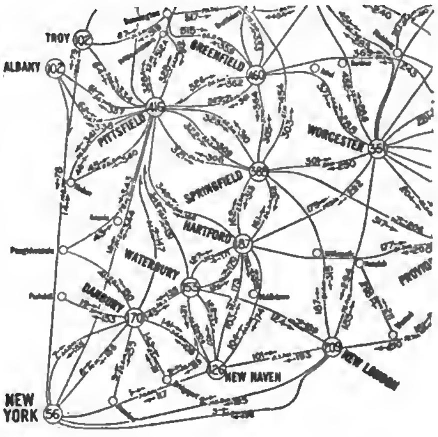

Fig. 3—A portion of the guide map from the front of the Blue Book by means of which routes, which are given numbers, may be located, preliminary to turning to the route map

The facsimile of route 162 (Fig. 4) is representative of the method employed throughout the book, and one of the important innovations is that of the "Baedeker feature," which gives a descriptive outline of the route, naming the historical points of interest, and affording to the autoist a clear insight into the things which will make touring pleasureable, if during his travels an attempt is actually made to appreciate the points of merit along the roadside. In addition to the descriptive outline, a brief statement of the condition of the road is put, and then comes the mileage, both total and intermediate, and instructions which will enable the tourist to identify the landmarks by means of which he will be enabled to traverse the route with a feeling of confidence, backed up by the assurance that every foot of the way was surveyed under the skillful eye of a topographical engineer of recognized capabilities.

Volume II of the Official Automobile Blue Book for 1910 covers New England most completely; it contains 30,000 miles of routes which were actually surveyed, as against 20,000 miles of surveyed routes as set forth in Volume I, as previously issued. There are many other differences worthy of comment.

(Continued, Page 901)

Route 162 **Hartford, Conn., Section**

Route 162—Hartford, Conn., to Springfield, Mass.—25.6 m.

Route map, page 187. Reverse route, No. 813

Descriptive Outline—Leaving Hartford via Windsor Ave., we pass at the right of Keney Park and follow the first highway laid out in Connecticut (1636) to Windsor, where "Plymouth Meadow" was the site of the first house erected in Connecticut, the materials, all fitted, having been brought from Plymouth, England. Crossing the Tunxis or Farmington River, we pass through "Palisade Green," which was Windsor's center of trade in the early days. On the right, 2 miles beyond, is the old Ellsworth mansion, restored by the D. A. R. Windsor Locks, located on the bank of the canal, connects with Warehouse Point by a suspension bridge (see Route 161). An interesting variant to our trip may be made through Suffield, which escaped the ravages of the Indian wars on account of the fact that the settlers paid the Indians £30 for the town site. Originally called Stony River, it became Southfield, then Suffield in 1674. Tobacco raising is the most important industry, and here the first cigars in New England were made in 1810. A pleasant trip along the bank of the Connecticut River, crossing on South End bridge, we turn left into South Main St., Springfield (see page [illegible].)

West side all the way, with connection across the Connecticut River to east side route at Windsor Locks; about half macadam.

Mileage Total	Intermediate	(For this and optional exits, see Hartford city map, page 189.)
0.0	0.0	**HARTFORD**, City Hall, Main & Asylum Sts. North on Main St., curving left with trolley (0.2 m).
0.5	0.5	Stone watering trough at irregular 4-corners; bear right with branch of trolley on Windsor Ave.—asphalt; becoming macadam. Direct along Connecticut River.
6.5	6.0	**WINDSOR.** Fork at end of green on right; turn right with branch trolley. Caution for sharp right turn under RR. with blind left turn beyond (6.6 m). Go through covered bridge over Farmington River (6.9 m) on stretch of fair dirt road.
9.3	2.8	Fork; bear right with trolley on dirt road, coming on macadam (10.4 m); cross RR. (11.1 m).
12.1	2.8	**WINDSOR LOCKS.** Straight on with trolley (Right across river at large electric sign connects with Route 161, at Warehouse Point—0.6 m beyond.)
12.5	0.4	Fork; bear right with trolley; (left is variant through Suffield, see note a). Macadam ends (13.2 m); Cross RR. (13.5 m)
13.6	1.1	Fork; trolley station on left; keep right, leaving trolley, on good dirt and gravel road. Join tracks (from left—18.7 m).
20.5	6.9	Fork in small settlement; bear right—leaving trolley—short stretch of sandy road, coming on macadam (21.3 m).
23.4	2.9	4-corners; turn square right, immediately cross long iron bridge over Connecticut River, and over RR. bridge just beyond.
23.8	0.4	End of road; turn square left into Pecousic Ave.

Fig. 4—Facsimile of a part of a page from The Automobile Blue Book showing the method of giving exact information

In the Building of a Private Garage

NECESSITY demands that the fuel problem be discussed at the same time as the garage construction, partly on account of the importance of the fuel in automobile work, and then in view of the hazard which will be run if the fuel is not properly handled. Referring again to the question of a "pit" in the floor of the garage, even allowing that it has a certain utility, the fact remains that it will serve as a pocket for vapor of gasoline and air. This mixture will reside in the pocket until it is borne away with a current of air, or it will be there when the motor is cranked, ready to respond to the touch of flame, as from the timer of the motor ignition system.

In a pocket such as this there is small chance of realizing a current of air, unless a means is provided, and even assuming that an artificial means is afforded, it must be of a character such as will require no attention at all, as a natural draught, which involves the use of a chimney of some height. Fig. 5 depicts a section through a garage showing the pit in the concrete floor. G is a drip of gasoline from the carbureter of the motor, and V represents the vapor which is formed; this vapor should be highly explosive; the proportions will naturally be rich at the bottom of the strata and will taper off as the top of the formation is approached.

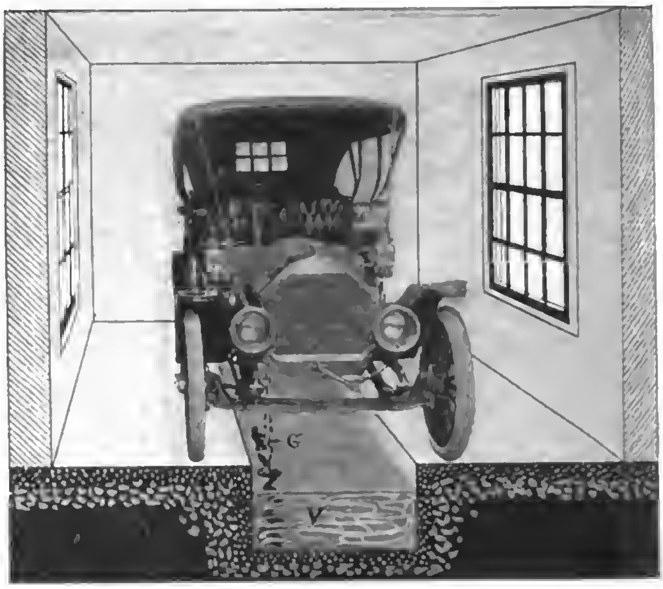

Fig. 5—Section of a garage showing a pit under the automobile to accommodate the workman and to trap in accumulations of explosive mixture

Some Features of the Gasoline Problem Exposed

In order to better appreciate the characteristics of gasoline, an attempt will be made to illustrate the points to be enlarged upon. Fig. 6 is intended to represent the landscape on a foggy day, showing the fog in somewhat dense formation, lying close to the surface of the earth. Referring to Fig. 7, the fog is clearing up from the ground surface under the action of a mixture of gasoline and air. The gasoline is obtained for the purpose from the barrel B; it will mix with the air as it boils out of the barrel (assuming there is an opening in the barrel for the escape of the gasoline) and the mixture of gasoline and air will be heavier than the air in its normal state, with the result that the mixture will form and displace the air (in the fog state) and fresh air will rush in so that the fog will be lifted. In this way, the use of gasoline will serve the purpose of lifting fog, but the plan has no practical significance beyond the illustration of the moment in the attempt to show that a pit under a garage is a dangerous device.

Taking the illustration Fig. 7 as proof of the fact that gasoline will hug the lower stratum, it is but a step to the conclusion that gasoline, if it dribbles out of a carbureter, or is turned out of any other source in a garage, will fall to the lower level and form an explosive mixture in proportion as it is diluted with air. If the low level happens to be a pit the gasoline mixture will be entrapped and it will rest in the trap until it is ignited. Fig. 8 shows the right principle to utilize. The floor of the garage is without any depression at all, and a means is afforded by which the mixture of air and gasoline, as it is formed, is driven out through openings at the floor line; there may be any number of these openings, but just a few, perhaps four, properly located will do the work as efficaciously as the occasion requires.

Sewer Connection Should Have a Trap

In a small private garage the best way to avoid complication is to do without a sewer connection, but if one is desired for any reason, the best way will be to provide a suitable trap, having in mind the fact that gasoline vapor will form in the sewer opening, and after it accumulates sufficiently, it will serve as a source of danger. Fig. 9 shows a rather pretentious "well" which is especially designed to overcome all sewer trouble, due to the accu-

Fig. 6—Landscape on a foggy day, used to illustrate the point to be made in relation to the displacing ability of mixtures of gasoline and air

Fig. 7—Barrel of gasoline sunk in the ground, leaking gasoline to the surrounding, as the liquid evaporates and mixes with the air surrounding it lifts the fog by displacement

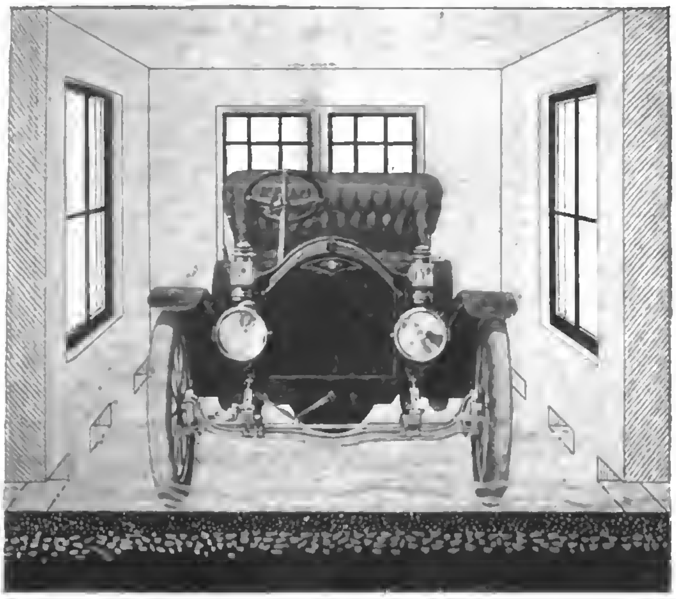

Fig. 8—Garage floor without a pit: openings in the walls near the floor, mixture of air and gasoline being swept away by air currents which are formed by draughts set up

mulation of gas; this plan is available for use in public garages, but since it is designed on the right principle the same idea will have to permeate any such application, be it for a public or a private garage.

In this example the cover of the "well" is perforated, the floor is supposed to slope toward the well, and when water drains into the well from the surrounding floor, it passes down and forms a seal; excess water will then pass out through the sewer connection. By connecting the lead from the air vent to a stand pipe, which should lead to the roof of the structure, a current of air will be set up and the gasoline vapor will be conducted up to the roof, will be well diluted with air en route, and will be borne away on a passing breeze to safety.

In a private establishment, especially if it is in the wooden district, with little room to spare, all the precautions as here intimated and many more as set forth in the various insurance rules, as promulgated by the Board of Fire Underwriters for the respective districts, should be observed, and it is something of a question as to the expediency of using a wooden garage under such circumstances. Modern concrete construction lends itself with facility to the purpose, and it might even be in the path of wisdom to make the doors and windows substantially fireproof, so that if a fire after starting cannot be smothered, it may be permitted to exhaust itself furnace fashion.

Prize for a Safety Automobile Crank

A French association for the prevention of accidents in industrial work has offered $300 in prizes for a crank or safety device for hoists, cranes, and all forms of lifting apparatus, and also for explosion motors, which shall, in the first case automatically stop the descent of the load, or in the second case, throw out of gear the driving action when not required. The invention remains the property of the competitor, who must himself be responsible for its due protection by patents. Drawings of competitive devices should be sent to the office of the Association des Industriels de France contre les Accidents du Travail, 4, Boulevard Saint-André, Paris, France. A non-return starting crank for gas engines, of simple design, was illustrated in the January, 1910, issue of *Machinery*, which may be of interest to prospective competitors in order to get informed of the most important recent developments along these lines. The above-named publication, from whose pages this note is quoted, will eventually render any further information in this matter.

Champlain Transportation Improved

THROUGH the courtesy of the Champlain Transportation Company, and the Lake George Steamboat Company, of which D. A. Loomis is manager, with headquarters at Burlington, Vt., THE AUTOMOBILE is enabled to state that the conditions at Baldwin are much improved; the highway is in far better shape than last year, and the former steep grades and deep sand may now be avoided. It is stated by the Transportation Company that after June 1 automobiles can be discharged at Baldwin as well as at Roger's Rock. The conditions on Lake Champlain are such that automobiles may be handled at Bluff Point. The Transportation Company can handle practically every kind of automobile, excepting the limousine type, provided they exceed 7 feet in height. The rates for transportation are given in the following tables, and it will be noted that the rates on machines include one person, and column C gives the fare for extra passengers:

Magnetos—The Leading Types Analyzed and Explained

By HERBERT L. TOWLE

LAST week it was explained that the flow of current in a rotating-armature coil reverses direction when the coil is vertical. It was also explained that no reversal of flow takes place when the coil becomes horizontal because the change of the included lines of force from decrease to increase is offset by the reversal of the coil itself. Owing to the reversal of current when the coil becomes vertical the ordinary magneto gives an alternating current with two maximums per revolution.

In order to give the lines of force a ready path from pole to pole and also to modify their direction in certain respects presently explained, the actual coil is wound over an iron core of the form shown in Fig. 10 last week. The winding is very heavy and fills approximately the space shown by the dotted lines. From the form of this core it is known as the H armature.

Fig. 11 this week shows in the three views *A B C* the influence of the core on the lines of force. In these views both core and coil are shown in section, and the reader is asked to remember that when the armature assumes the position *A* the several windings of the coil are *vertical*—the position of zero current. When the armature is in position *C* the current is a maximum.

As the drawings show, the effect of the core is to concentrate the lines of force into the iron. Consequently when the armature has made an eighth of a turn, the magneto field is distorted somewhat as shown in *B*. When the core approaches the *C* position the lines of force abruptly change direction and pass from one pole-piece to the other through the curved ends of the core, leaving the coils destitute of magnetic field. When further rotation of the armature has carried the core past the *C* position the lines of force rearrange themselves as abruptly as before, passing now from the lower left end of the core diagonally upward to the right-hand pole-piece. The effective work of the armature is thus concentrated into a narrow range or arc of rotation, and during the remainder of the half rotation little or no current is induced. Fig. 12 indicates roughly the character of the resulting curve of potential.

It is evident from Fig. 12 that an effective spark can be produced only within a certain range of armature positions. Precisely what this range will be depends on the actual potential, which varies with the speed. If the curve *A B C D*, Fig. 12, represents the varying potentials at 500 r.p.m., the curve *A B' C' D* will be approximately the curve at 1000 r.p.m. At very low speed, e.g., when cranking, only the peak of the curve will produce an effective spark. It is customary to set the armature in relation to the crankshaft so that when the spark occurs the core will have approximately the *C* position, Fig. 11, with maximum advance, in order to get the strongest spark when the most rapid flame propagation is desired.

From the character of this type of magneto it is evident that its rotation must keep step with the engine. As a 4-cylinder, 4-cycle engine delivers one impulse per half revolution, it follows

ke-and-break system is simply a device

by an electromagnet instead of by mechanical means. The electromagnet is energized by the magneto current itself, and is timed merely by the strength of the current wave. In other words, the magnet in the plug attracts its "armature" and thereby breaks contact at the igniter when the current strength is sufficient to cause the magnet to overcome the very light spring which normally maintains contact between the points.

Fig. 15 shows an early and now obsolete arrangement for this purpose. A magneto is wired up to an induction coil exactly as if it were a battery, with the single exception that the switch is arranged to short-circuit it instead of to open the circuit. The interrupter is arranged to make and break contact mechanically, and is mounted on the armature shaft, though shown separately for clearness. When the magneto is used in this way a condenser is necessary, see Fig. 15. The condenser consists of a number of sheets of tinfoil, of which alternate ones are electrically connected. The leaves are thus connected, "half and half," to the circuit on each side of the break at the interrupter. If there were no condenser, a heavy spark would appear at the interrupter contact points, and, by delaying the dying out of the current in the coil, would weaken and prolong the flow of secondary current. In order to have the primary current die out as quickly as possible in the coil, and thereby deliver its maximum inductive effect, the condenser is provided to absorb the momentary extra current. The manner in which it does this need not here be explained; suffice it to say that the size of the

Fig. 14, but the rocking stem is actuated

condenser must be proportioned to the quantity of extra current which it is to absorb. Too small a condenser would fail to suppress the spark, and the contact points would therefore burn away with injurious rapidity.

The arrangement shown in Fig. 15 does not utilize more than a minute fraction of the energy of the magneto. A much more efficient arrangement, though less easy to understand, is shown in Fig. 16. This is now the standard arrangement for magnetos having separate coils. It will be seen that here the coil is not in series with the interrupter; the latter, in fact, simply short-circuits the armature. The induction coil, which is outside the magneto, has a primary winding of somewhat long and fine wire, so that without the action of the interrupter this coil would take very little current. However, when the interrupter breaks contact, the momentary extra armature current due to the break is strong enough to make itself felt in the induction coil as a sudden rush of current, and this momentary rush induces a high-tension current in the surrounding secondary coil. In this diagram is shown the distributor as arranged for a 4-cylinder engine. The secondary current from the coil is led to a revolving arm which delivers current successively to the four different spark-plug cables. The distributor is necessarily geared to run at half the speed of the armature and interrupter, since it supplies the four cylinders only once in two revolutions. To shut off the current the armature is short-circuited as before.

(To be continued.)

Aeronautic Progress Along Constructive Lines

By MARIUS C. KRARUP

(Continued from last week.)

SINCE the machine cannot turn about its axis, the canting is therefore in reality effected by raising the outer end, and consequently also raising the center of gravity. And the preliminary increase of tilt of the outer wing helps to make this effect of centrifugality decisive, or, in other words, helps to steady the balance and avoid fluttering. In a machine differently balanced, it would not be essential to steering, however. The main point is, that in some manner the centrifugality must be spent without interference with equilibrium. It cannot be permitted to drive the machine away from its intended course, as it does in the case of a racing car at a sharp turn in spite of ground friction. So, it must be harnessed to do other work.

While so many factors and forces are simultaneously involved in the balanced turning of an aeroplane, that it becomes difficult to speak clearly and at the same time correctly about the requirements, it is clear that design and control must in some manner permit the center of gravity to obey the centrifugal impulse, by taking it farther outward in the curved movement than withstanding possible adverse influences of the wind, becomes an important item in the studies of the aeronautic designer. A glance at Fig. 2B will suggest how complicated the factors entering in equilibrium may become at a turn, with a biplane, when the lower plane may get partly in the way of the upper one, so far as resistance to lateral motion or wind action is concerned, thereby causing the center of resistances to such lateral motion or wind action to shift downward and outward, while the center of gravity will tend to swing around the new center, unless kept steady by the action of the vertical rudder and suitable changes in the tilts of the main planes.

Fig. 2C, representing a monoplane with dihedral angle and low center of gravity, indicates a method for resisting centrifugal action, mainly by the resistance of the horizontal wing at r2 against downward vertical displacement and an increased resistance from the upturned wing at r1 against lateral displacement.

The question of equilibrium at turns and the closely related

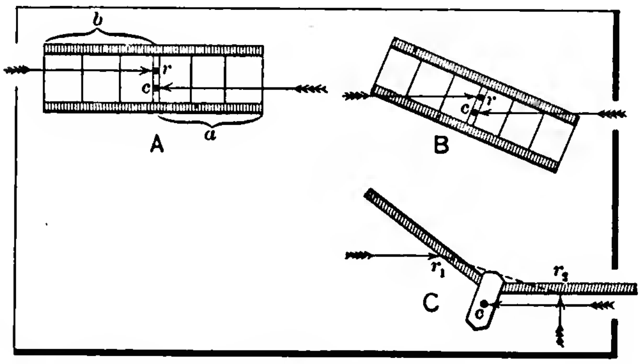

Fig. 1—A, B and C, Action of Centrifugal Force in Aeroplane Flight

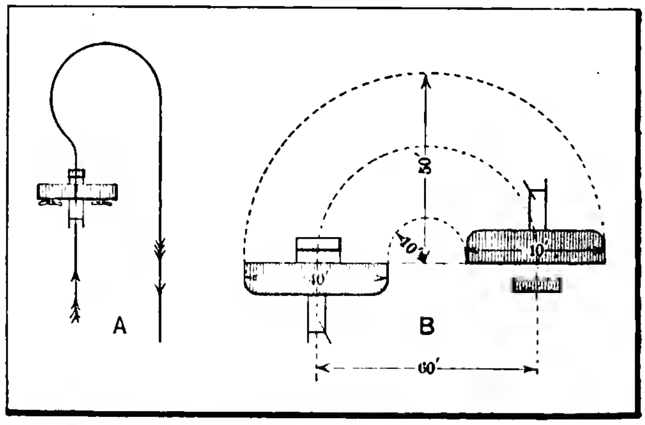

Fig. 2—A and B, Illustrating Requirements in Turning with Biplane

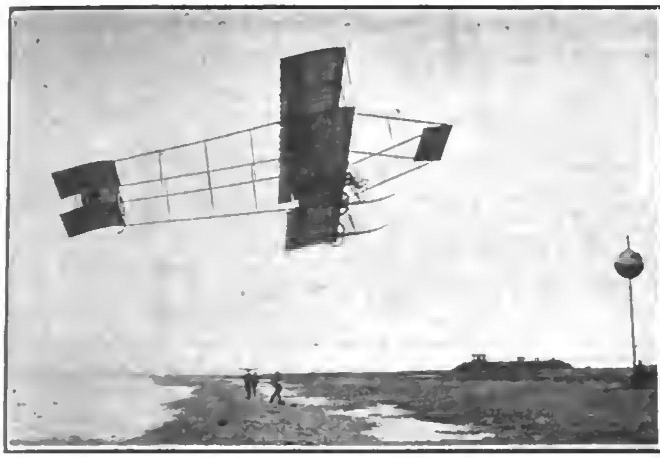
it was before the movement was begun, and also that the action wbich produces this result must at the same time be made to produce increased air resistance against lateral movement of the machine, since the resistance to lateral movement is ordinarily very small and quite insufficient for offsetting centrifugality, especially in a biplane with straight front edges.

The canting of the machine serves both these purposes and therefore also serves to maintain equilibrium. It is not an inconvenient incidental effect of the vertical rudder action required for steering, like the listing of a boat, but a necessity. And the means for producing this camber and for controlling it, not-

question of equilibrium in a side wind, can probably not be discussed to advantage in a general way, but only in detail and with reference to the different types of fliers separately. All flying creatures possess the faculty of lowering or raising the center of gravity with relation to the centers of air resistance, both in the direction of motion and laterally, and it does not seem quite settled, as yet, whether this element of mobility can be dispensed with in aeroplanes intended for flight in all kinds of weather, but it is a physical and mathematical certainty that engine power would be required for quickly raising the center of gravity of a machine during flight, once it had been lowered.

Some Effects of Curved Planes

IT is stated that the French builders of monoplanes are abandoning the deeply curved surfaces which were at first adopted with a view to getting a maximum of sustentation from the relatively small areas inseparable from monoplane design. They are at the same time providing the tails of these machines with larger "feathered" appendages, both vertical and horizontal, as in the latest Antoinette type, but opinions are divided with regard to what may be expected from these changes. Decisive performances are still missing, and a minority of the engineers whose ideas find vent in public take an opposite position. It is charged against the deeply curved planes that they make it difficult to maintain the equilibrium of the machine. One well-known engineer, René Arnoux, believes that this is most important, and that sustentation should be freely sacrificed in order to improve the balance, and to this end be proposes that the hollow of the planes should be turned skyward instead of earthward, since this is what the wind does to the planes now used, in too many cases. He contends that the balance would thereby become automatic, the stability perfect, while the sustentation would not be sacrificed to the extent of requiring areas three to four times greater than with present design or much bigher speed, since sustentation may also be obtained by higher tilts. It is generally admitted that nothing short of experiment and practice can fully decide these questions, by determining just what the resistances to propulsion and the sustentation are at various tilts and with various shapes of the planes, and the scientific world in France has gone into this subject with much energy. Rateau and Brillouin, both authorities in physical science, were the first to experiment carefully.



Rawlinson Making Turn at Nice Meet with Farman Biplane

Paulhan's Farman Biplane as Shown on His Tour in the U. S.

but the results obtained by them have been superseded for practical purposes, through the installation of an elaborate aerodynamic test station by Gustave Eiffel, the designer of the Eiffel Tower. Here the experiments embrace flat planes and planes of many different curvatures, and designers are watching the results with anxiety. They have shown, among other things, that flat planes give a maximum sustentation at a tilt of 30 degrees, and that the suction produced at the top of the plane is equally important with the thrust of the pressure surface; also that the rise in sustentation from 10 deg. tilt to 30 deg. is very slow.

At the aerodynamic institute at Koutchino in Russia, experiments have been made by Riabouchinski giving the sustentation and also the horizontal resistance obtained from planes of different curvatures at different tilts. At a tilt of 7 degrees, which is very practical, the proportions are found to be as follows: For a flat plane, 215 sustentation to 24 resistance; for a plane with a hollow 1-30 as deep as the fore-and-aft extension of the plane, 283 sustentation to 22 resistance; similarly, for a hollow 1-20, the figures are 310 to 32; for 1-16 they are 386 to 44; for 1-12, 390 to 45, and for a 1-8 curvature the sustentation rises to 440, but resistance at the same time rises to the very high figure of 81.

The net result is therefore that resistance to propulsion rises considerably faster than sustentation, when the curvature exceeds 1-30, but that, nevertheless, the weight-supporting qualities of a given area can be multiplied almost by 4 by increasing the curvature to 1-8. And, as the designer has the choice between reducing the resistance against propulsion by reducing his area and curvatures, the chances for capable engineers are immense.

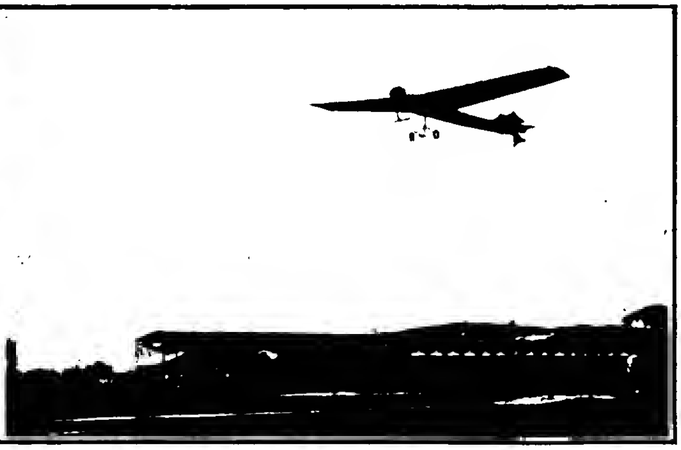
Two biplanes whose dimensions are known, having been stated authoritatively by the owners, illustrate how wide the variations are which are consistent with successful flight. One belonging to Maurice Farman has 1-50 curvature, 45 square meters area (484.37 square feet), carries 600 kilos (1322.77 pounds) all up, or 13.833 kilos per square meter (2.73 pounds per square foot), and it reaches a speed of 85 kilometers (50 miles) per hour. The other, belonging to R. Esnault Pelterie, has 1-12 curvature, 23 square meters area (247.57 square feet), while it also carries 600 kilos (1322.77 pounds) all up, or 26.100 kilos per square meter (5.34 pounds per square foot), but despite of its smaller area it cannot make a speed in excess of 70 kilometers per hour.

Aviation Machines at the Meets

NO new construction feature enabling aeroplanes to brave unfavorable weather or permitting substantial design, with a minimum of guy wires and struts, has been brought to public attention at the aviation meets during the past two years, but by lengthening, lightening and reducing the wind-catch of tails, the types shown at the 1908 meet at Rheims have been made steadier fliers in fair weather.

Disciples of Henry Farman carried off the honors at the recent meet at Nice on the Mediterranean Sea, as well as in the London-Manchester flight by Paulhan. In both cases, the winner as well as most of the non-winners flew Farman biplanes. The characteristics of these are the single-plane "tilter"—as the elevating or tilting rudder might perhaps be called, for short—the tiller, either single or double, placed with the trailing planes far in the rear of the main planes, the single rear propeller, and the adjustable rear-edge flops attached to the end sections of the main planes. One of Farman's latest models has the upper plane extending beyond the lower plane at both ends.

Effimoff, Winner at Nice Meet, Began Flying in December



Latham in His Monoplane at the Nice Meet

Engineering Digest

A carefully abstracted digest of accounts of engineering activities as they are reported in society transactions and technical papers throughout the world.

The Society for Smokeless Automobile Traffic at 21 Bülowstrasse, Berlin, recently exhibited an apparatus guaranteed to accomplish the complete combustion of the smoke and gases arising from an over-supply of lubricating oil in the operation of internal-combustion engines. The apparatus is attached to the exhaust pipe, and the combustion is obtained by means of a suitable device for admitting fresh air and mixing it with the exhaust, while ignition of this mixture is secured by means of the flame accompanying the exhaust. The utility of the apparatus is demonstrated by the company in Berlin on an automobile, and it is found that both the odor and the blue smoke resulting from bad oil or bad regulation of the oil feed are obviated.—*Allgemeine Automobil Zeitung.*

Complete statistics have been collected in the German Empire showing just how many automobiles and motorcycles are in use in each of the provinces, what their power is, and for what purposes they are employed. But comparison with similar data for 1909, 1908 and 1907, it is shown that the increase from year to year has been at the rate of about 35 per cent each year for automobiles, but much less pronounced for motorcycles. The latest figures are in brief as follows, for the whole Empire: 22,283 motorcycles and 24,639 automobiles, and of the latter 12,595 have less than or not over 8-horsepower, 7,341 up to 16-horsepower, 4,695 up to 40-horsepower and 98 more than 40-horsepower. Industry and commerce employ 7,152 automobiles and 11.997 motorcycles; sport and pleasure claim 10,562 automobiles and 7,569 cycles; the professions and special avocations make use of 3,175 vehicles and 2,255 cycles; 3,285 vehicles are in public service for hire, but no motorcycles; 131 cycles and 328 automobiles are used in government service by postal, police and railway employees, while agriculture and forestry make use of 331 cycles and 137 automobiles.—*Allgemeine Automobil Zeitung.*

The two or four-cylinder Cote motor is of the two-cycle type. It was brought out two years ago, and has lately attracted attention in France, where a vogue for valveless motors is bestirring the designers. In the Côte motor the lower enlarged portion of one cylinder, in which works the enlarged lower portion of the corresponding piston, is utilized for the preparation of the explosive charge for the next explosion in the adjacent cylinder, and vice versa. The charge is driven from each auxiliary cylinder chamber into a transverse sleeve divided concentrically into two transfer posts, and from there into the cylinder which is to be fired. Thus, neither is the crankcase used for compression of the charge, nor is there employed an auxiliary cylinder with separate piston from which the charge is taken. In brief, each cylinder in the Côte motor is composed of a high portion which works and exhausts when the piston descends and which compresses its own charge, when the piston rises, and of a low portion which draws in a charge from the carbureter on the downstroke and feeds this charge to the adjacent cylinder on the upstroke. The construction details indicate the possibility of economical manufacture, while tests conducted by the A. C. of France show fuel economy and power efficiency.—*Omnia,* April 16.

Every time some new manifestation of human insight buds forth, the people get busy swaddling the new life with regulations, says Mortimer-Mégret in *La Pratique,* referring to the enforcement of antiquated automobile traffic rules and projected restrictions upon aviators.

It is usually assumed that the valve spring for a four-cylinder motor should be calculated so as to produce a certain pressure per square inch or square centimeter in the valve seats, such as, for example, 40 pounds per square inch, and also that it is advisable to shape the cams so abruptly that the spring in action passes quickly from its maximum to its seating tension. With a view to obtaining a minimum of noise and wear of the valve mechanism, and the valve seats as well, K. Praetorius, of Charlottenburg, Germany, calculates graphically the minimum strength required of a valve spring for given dimensions of a motor and arrives at a shape for cams by which the expansion of the spring is made more gradual without interfering with the proper opening and closing time for the valves.—*Der Motorwagen,* April 10.

Usually automobile fire engines are fitted with pressure pumps of the reciprocating type. *Le Génie Civil* for April 2 describes one in which the motor, when not used for driving the vehicle, is connected by a multiplying gear with a centrifugal pump, giving the latter a speed of 2000 revolutions per minute. The designer, Karl Metz, of Karlsruhe, Germany, places a large water reservoir behind the driver's seat on a truck chassis, and the centrifugal pump, which is located in the rear, is thrown into mesh with the first pinion of the transmission, as soon as the vehicle arrives at the place of fire. By means of two pipes, the pump may draw its stream of water either from the reservoir or from a suction pipe to be connected with another source of supply, and the reservoir may be filled either by the pump through a third pipe or from a street hydrant with pressure, by attachment on either side of the vehicle to a crosswise feed conduit on top of the reservoir. The pump uses 15 to 30-horsepower to discharge 600 to 800 liters per minute, at a pressure of 6 to 10 kilograms per square centimeter and can throw a stream of 19 millimeters diameter a distance of 50 meters, or else, by different attachments of discharge hose, three streams of 12 millimeters diameter a distance of 40 meters. The motor gives 35 to 40-horsepower at 900 to 1,200 revolutions per minute and a vehicle speed of 25 to 30 kilometers per hour. With ladder, pipes and hose reel the vehicle weighs about three tons.

By means of a series of experiments with one cellular radiator and two tubular radiators, the engineer Walther Freiherr von Doblhoff has reached confirmation for a number of theoretically deduced formulas by which the automobile designer may determine the dimensions required of a radiator to be used with a motor of a given power and under any ordinary given set of conditions. Every step in the author's reasoning, is accounted for in text, illustrations, plotted curves and interim formulas, the whole forming a lengthy document running through several issues of the *Zeitschrift des Vereines Deutscher Ingenieure,* concluding in the issue of April 2. Fine distribution of air and air cooling surfaces, with considerable resistance to the passage of the air, is found of greater importance than fine distribution of cooling water. It is concluded to be a false principle to let as h the radiator as possible. The two main

ars been seen in France, says this

authority, as since this company adopted the Knight-Minerva motor. It is a fact against which nothing will prevail. The public likes them, and what the public wants it gets. The Panhard company, slow to move, has adopted this type, and the other great houses have quickly comprehended the necessity for getting up a valveless motor of their own. The Mercedes people, after working on the problem for three years, will spring a valveless sensation in 1911. The Delaunay-Belleville, the Renault, the Delahaye, the Bayard-Clément, the Hotchkiss will not remain behind. Ten of the great automobile companies of the world are contemplating and working on hydraulic transmissions. Louis Renault has for several years filed patent after patent in this line of construction, and automobile history shows that Louis Renault has never been mistaken about the trend of developments.

Air Resistance to Racing Cars

Public interest in aviation and propellers for aeroplanes has brought to the surface in France, the land of mathematical deductions as the means for guiding practical work, many questions relating to the air resistances against automobiles. A spirited controversy has arisen with regard to the possibility of reducing the atmospheric resistance against racing cars by placing a suitable traction-helix in front of the car, to act presumably not only by direct traction effect but also by scattering the atmosphere, so that the latter will strike the body of the car with diminished force. The arguments pro and contra bid fair to continue until proven or disproven by practical demonstration. The editor of *La Vie Automobile* in a recent issue offers a calculation of the air resistance overcome by the Benz racer of 250 horsepower in the performance when this vehicle made one mile in 27 33/100 seconds. "This car," he writes, "at first had an ordinary hood and a straight-front radiator. Then a wind-splitting front was substituted, but it was especially the subsequent modifications of its rear forms which produced extraordinary results. The tapering of the rear to the shape of an armor-piercing projectile made the vehicle with one bound gain 12 kilometers per hour. But the power absorbed by the atmosphere remains considerable, as may be seen from a simple yet sufficiently exact calculation.

"In running order the vehicle weighs 1350 kilograms. Its speed on the occasion referred to was 59 meters per second, and the air resistance at this speed comprises two elements. One is independent of the speed, being the product of the car's weight with the coefficient of rolling friction, which is about equal to 12 kilos per thousand kilos of car weight. The other is proportionate to the square of the speed, multiplied by a certain coefficient, which the special shape of the Benz car permits one to place at 0.07.

"With these figures, the unit of resistance becomes, thus:

Resistance $= (1.35 \times 12) + (0.07 \times 59 \times 59) = 259.87$ kilograms.

"The product of this unit with the speed in meters per second will then equal the work performed at the wheel rims in kilogram-meters.

$$259.87 \text{ kilos} \times 59 \text{ meters} = 15{,}333 \text{ kilogram-meters.}$$

which is the equivalent of about 204 horsepower."

According to the editor of *La Vie Automobile,* the power consumed in air resistance at a speed of 212 kilometers per hour, with a car shaped as favorably as possible, therefore amounts to 191 horsepower out of a total of 250, and this, by the way, gives an efficiency in the power economy of the car of about 80 per cent. But it is evident that the accuracy of the calculation depends largely upon the more or less arbitrary factor, 0.07, chosen to represent the special shape of the vehicle.

A new horsepower-rating formula has been brought out by Louis Lacoin and is presented in the current number of *Omnia.* This is figured from the cubical capacity of the cylinders, which of course varies with the stroke, so that the final form of the formula takes into account the stroke as well as the bore, also the speed. This formula, which will be given in next week's issue of THE AUTOMOBILE, carries the bore with an exponent less than 2, in which it differs from all previous rating formulas.

Construction Ideas From Designers Abroad

New Longuemare Carbureter

IN the latest product of the famous carbureter builders, the brothers Longuemare, of Paris, a number of distinctly different features are to be found. These include a bypass for heated gases, a novel needle adjusting means, a new idea of gasoline strainers, and some more. The carbureter is shown below in the drawing, a cross section, and in the photograph of the assembled device. In the drawing, it will be noted that there is a separate float chamber, communicating with the bottom of the vaporizing chamber. Inset into the bottom part of the latter is an adjustable nozzle, and the air inlet, which takes the form of a series of round holes through a circular band, the number and size of the openings through which are governed by a sleeve around the exterior, which may be rotated at will.

In the drawing, A is the hollow metal float, into the chamber for which the gasoline flows from above, the movement of the float up and down governing the amount of fuel permitted to enter in the regular way. Before reaching the float chamber, however, the gasoline must pass into a spherical chamber, within which is placed a circular gauze strainer. This strainer is placed around a hollow vertical post, through openings in which the gasoline flows inward and thence downward. The different form of the strainer has an influence upon the cleaning of the same, and its ready removal and insertion for that purpose and after the cleaning is over.

B is the housing for the needle valve G, which projects up through the nozzle F into the vaporizing chamber, which consists of a perfectly vertical, concentric tube with a sort of double cone insert, to give the venturi tube effect. This tube, lettered C, is but a force fit in place, and were it not for the pipe O, could be slid up or down to improve the carburetion effect. The needle G is movable up and down, the adjustment being made from an outside point, namely, the regulating nut K. The latter moves the regulating rod or stem J up and down, with a corresponding motion of the needle down and up; that is, for a downward motion of the rod, the needle moves up and vice versa. In this sliding action, the needle is guided within the housing B, and its quick action is opposed by the spring H. The lever I, pivoted off center, gives the proper motion to the needle. The lower part of the needle is not only widened out, or enlarged in diameter to fit the sides of the chamber, but it serves a double purpose also in being perforated with small holes through which the gasoline may flow.

Around the outside of this part of the carbureter is a large annular chamber, through which holes N N give access to the air, while a thin member around the outside of this slides around to partially close or open these holes, thus regulating the amount of air. The outer sleeve is shifted by hand. In passing into the vaporizing chamber, the fuel carries the air, or rather the air carries the fuel up into the passage, which connects to a longitudinal passage at right angles to the former, the latter passage leading to the cylinders. Just at the level of the top of the nozzle is placed the hollow tube O, which communicates with the chamber on that side of the carbureter, this chamber being connected at the top to the inlet pipe, but beyond the throttle valve. This pipe then acts as a bypass around the throttle, and the taper pointed screw P is used to regulate the amount of gas which may thus be shunted. Although the present carbureter comprises but one of these bypasses, the idea is capable of infinite enlargement. By this means, a larger carbureter could be pressed into service, for with proper regulation of the bypasses, as to number and amount of gas allowed to flow, the large size of the vaporizer could be practically nullified. However, the present use is to develop very slow speeds, the bypass permitting some fuel to reach the engine, when the throttle is completely shut off, the speed thus developed being very, very small, according as the adjustment at P is made very small. It will be noted that provision is made for hot water jackets around the entire vaporizing chamber, with the exception only of the side on which the bypass is located.

Dennis Worm-Driven Rear Axle

While worm driving has not made a great deal of progress in this country, on the other side, where for commercial vehicle work it received its first and best tryout, it has achieved a fair degree of success, and each month develops a new adherent for this quiet and efficient drive. In the Dennis cars, the drive has it staunchest and most consistent adherent, so it is not strange that the latest product of Dennis Bros., Ltd., of Guilford, Eng., a light 20-horsepower touring car, embodies a worm-driven rear axle.

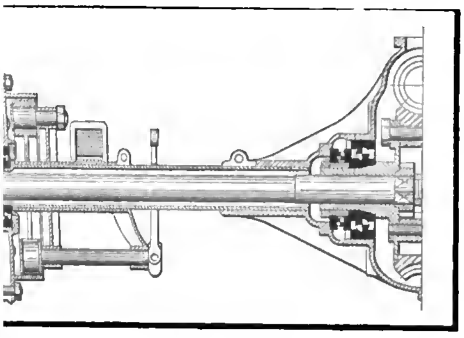
ıer English Slide Valve

marked success of the Knight engine in Eng- have been prolific producers of engines with from the ordinary poppet type. These have in-eeves, piston valves, disc valves, valves of the the reciprocating type, and many more. The nis very interesting line is that shown herewith, ıng being reproduced. In this, a form of trunk ithin a sliding sleeve, both the piston and sleeve being actuated by means of eccentrics off of a secondary shaft, a la Knight. The two valves, for such they are despite their form, are placed in an offset portion of the cylinder casting, conforming to the L type of cylinder casting offset.

As the drawing shows, there are two slots in the opposite walls of the sleeve, which is, in addition, open top and bottom. The open bottom is not used, but the open top is, the opening C being the free exhaust, or the place where the exhaust pipe is attached. The inlet operates through the registering of the diagonal slot through the inlet piston with the two slots in the sleeve, the latter at this moment—according to the correct timing—being just opposite the combustion chamber passage, thus giving the inlet gases a free, though slightly inclined, passage from the pipe upward to the combustion chamber.

At the right of the drawing, in the smaller figures, is shown a modification of this same idea, this being in the form of a pair of concentric rotating discs or shells. The action is the same and so is the shape of the two discs, the motion of rotation of these, located in the head, being substituted for the more complicated one of reciprocation in a separate chamber.



Worm-Driven Rear Axle for Touring Car Use

Welded Steel Pistons, Now

Steel pistons have long been a dream of the successful designer, but, for various reasons, those which have been tried have not been a howling success. In racing cars, these have found a somewhat limited use, being cut, in that case, from a solid steel bar, and not made from a casting. This process is too expensive for use on ordinary touring cars, so that form is not useful. Nevertheless, the idea that steel pistons were good has persisted. The very latest development in this line is that shown above, being a pair of pressed steel, half-round shells, electrically or otherwise welded together to form a whole-circular piston.

This makes the steel piston not only light in weight, an advantage always claimed, but also cheap to produce, of a very homogeneous metal, which has a very uniform thickness. With so many advantages, and few, if any, apparent disadvantages, the steel piston may soon come into its rights. If this means longer life, as engineers claim, it will be a good move.

Irreversible Steering Explained

Editor THE AUTOMOBILE:

[2,256]—What is an irreversible steering gear? Will you please explain this in an early issue of your excellent paper, "The Automobile"? A SUBSCRIBER.

Fitzgerald, Ga.

When any combination of gears, or train of gears, or gearing is of such a nature or so arranged that motion in one direction is properly transmitted through the whole train or throughout the gearing, while motion in the opposite direction is not or will not be transmitted through the train, the whole is said to be irreversible. In the simple case of two spur gears in mesh, if one (A) be moved, the other (B) will also move just as freely. So, too, if the other (B) be moved, the one (A) will respond and move just as freely as did the last gear in the first case (B). This form of gear is then strictly reversible, since motion given to any part of it, is properly and easily transmitted by all other parts. If now a worm and gear be used as an example, motion of the worm will turn the gear, but the opposite of this is not so, that is, turning the wheel will not turn the worm. To be exact, it will turn it a little according to the shape, size, and character of the threads of the worm and the teeth of the gear, but all of the motion given to the gear will not be transmitted through the worm, in fact, but a very small fraction.

Now, most steering gears are composed of an internal and external worm, a worm and gear, worm and nut, or worm and wheel, all including the nearly irreversible worm, so that the statement that a steering gear is irreversible only means that it includes a worm in its make-up. The word irreversible, as applied to steering gears, is somewhat of a misnomer, for as explained above, all such steering gears are reversible, but to a very limited extent. A more correct word for use in this connection would be semi-irreversible or the phrase, partly irreversible. or even, nearly irreversible.

Gears and Gear Cutting Methods

Editor THE AUTOMOBILE:

[2,257]—What kind of a gear would mesh with the "wide, strong gear" shown on page 327 of the February 10, 1910, issue of "The Automobile," in the article relating to gear and pinion failures? MURRY FAHNESTOCK.

Allegheny, Pa.

While the sketch alluded to by this writer is a little bit vague, the appearance seems to identify it as one of the new gears with stub teeth. This is a new form of gear which has been brought out by the makers of a gear-cutting machine, and is especially adapted to that machine's work. The gear has a different angle of obliquity, or angle which the common tangent to the teeth, when they are in contact at the pitch point makes with a line joining the centers of the wheels. This angle, which, in the ordinary involute form of tooth, is 15 deg. or close to it, is in the stub tooth made nearly 21, 20 1-2 to be exact. The result is that the teeth, whose proportions are determined somewhat closely by this angle are materially altered. In the stub tooth, the result is a short, fat, and, consequently, strong tooth. Any stub tooth of the same pitch will mesh with this one. Thus, if it were of 6-8 pitch—all stub-tooth gears have hyphenated pitches on that order—any gear of 6-8 pitch would mesh with it properly.

This form of gear tooth is meeting with great success, and is being used to an increasing extent in the automobile business.

Ways of Altering Compression of Motors

Editor THE AUTOMOBILE:

[2,258]—I wish to know how I may be able to alter the compression in my motor. It is not high enough to suit me and I am of the opinion that I will realize more power if I increase the compression quite a little. JOS. F. O'DAY.

Brooklyn, N. Y.

This matter was very well handled in *Omnia*, Paris, April 23. The gist of the discussion was as follows:

When it is desired to increase the compression the most general method, declares the author, is to attach a plate to the bead of the piston. This, however, has the distinct disadvantage, especially for a single-cylinder motor, of upsetting the equilibrium. To overcome this it is necessary to touch up the flywheels, which generally carry counterweights. For a four-cylinder motor the inconvenience is less, except in cases where the motor is balanced cylinder by cylinder. There is still the disadvantage of an increase in the weight of the reciprocating parts which is likely to reduce the number of revolutions per minute. A more mechanical method is to machine a special piston with a dome-shaped head. This, however, is costly. A cheaper method is to make a new and longer connecting rod. If the compression bas only to be slightly increased a clever smith can lengthen the connecting rod by heat treatment. This, however, is a delicate operation. Compression can be slightly increased by machining the valve plugs until they penetrate further into the cylinder. The angles should be rounded off in order to prevent preignition, and naturally enough space should be left to allow of the normal lift of the valves. A method often employed is to plane the lower face of the cylinders, or the upper face of the crankcase, thus bringing the head of the piston nearer the top of the cylinder.

Comparison may be decreased by the use of dome-shaped valve plugs; by changing the piston for one with an incurved head, or by putting a plate between the bottom of the cylinder and the crankcase. Although compression can be increased by placing a metal plate on the top of the piston, the contrary cannot be done to decrease compression, the piston generally being so thin that any planing of its surface would rob it of necessary strength. It is not advisable to change the connecting rod, for there will be danger of the lower part of the piston touching the top of the crankcase. If the metal is taken off the piston to overcome this the balance of the motor will be destroyed.—*Omnia*, Paris. April 23.

Oiling Practice with Disc Clutches

Editor THE AUTOMOBILE:

[2,259]—My automobile has a friction clutch of metal, made one steel disc, then one brass, then steel, then brass, and finally steel. All these are about a foot in diameter. I wore out one brass ring last year, and had to get a new one. The brass rings carry cork inserts. Should I oil the clutch or not? Please answer through the columns of "The Automobile." R.

Montgomery, Pa.

Doubtless reference is had to disc clutches, as the one described in the letter above would be a five-disc clutch. As to lubrication of these clutches, opinions differ, some experts saying that no oil is preferable, while others think that wearing or rubbing parts should be oiled whether in a clutch or somewhere else. The clutch described sounds like that of the Stevens-Duryea car, the makers of which advocate the use of a dry clutch, that is, no oil. If it were not for this fact, the advice would doubtless be to use a light oil, with which practice the majority of makers seem to agree.

The argument against the use of oil is that it makes the clutch slip more than it should, while being of no use whatever when the car is running and the clutch is engaged. It is also said that oil in a disc clutch makes the discs cling, in other words, the clutch does not disengage as quickly as it should. In the presence of cork inserts there really is less necessity for the oil than without them, for the corks furnish the wearing and contact surfaces of the clutch, and not the metal to metal faces.

Very Puzzling Case of Misfiring

Editor THE AUTOMOBILE:

[2,260]—We recently received in trade a Buick Model "10." The motor was not acting at all well and we overhauled it completely, cleaning cylinders, grinding valves, cleaning carbureter, timing valves by marks on flywheel and setting all the distributing and contact points in Remy magneto according to Remy instructions. After car was completely assembled we tried it out on the road. The motor ran beautifully at high rates of speed, but lurched and ran on two rear cylinders only when throttled down. This seemed to indicate magneto or carbureter trouble. First we tried all adjustments of carbureter with no better results (the carbureter is a Model "D" Schebler). Then, following Remy instructions, which read: "If motor misses with spark retarded at slow speed adjust the contact screw, by loosening about one-quarter turn," we adjusted the magneto with no better results. The timing is right, the valves all seat, there are no obstructions or leak in manifold, the magneto gives equal spark to all four cylinders, but still when the engine is throttled down, cylinders one and two do not fire steadily. We changed plugs, putting plugs from 3 and 4 into 1 and 2, but cylinders 1 and 2 still refuse at low speeds while running fine when engine is on full throttle. There is not too much oil in crankcase. In your opinion, what is the trouble?

Chippewa Falls, Wis. BARKER AUTO COMPANY.

Granting that the valves are right, that the cylinders and combustion chamber are clean, bright, and free from carbon deposits, carbureter clean, timing correct, and spark plugs in good condition, the only thing which can cause the misfiring in the two front cylinders is either a defect in the wires leading to those two cylinders, or a defect in the fuel supply to the same two. Since the trouble has been proven not to lie in the valves, timing, spark plugs, or carbureter, and has been isolated in the two front cylinders, and that too, only at slow speed, it is a fair assumption that the wires to the two cylinders in question may have defective insulation so as to cause a short circuit, which would deprive the cylinders of a spark; may be broken but with the ends held together at smooth speeds, but jarred apart at slow speed; may be worn somewhere and jarred against metal at slow speeds, etc. Or the inlet pipe to those two cylinders may be clogged with waste or something of that sort. It is even a possibility that the timing points in the magneto, which connect with the two bad cylinders, may be somewhat worn. In any case, to fix this trouble, confine your attention strictly to the wiring, fuel supply, and exhaust system of the two cylinders which have gone wrong.

Handling Liquid Carbonic Gas

Editor THE AUTOMOBILE:

[2,261]—Will you please advise me as to the best method of handling carbonic acid gas to recharge little drums with it for tire inflation? In my business I handle 20 and 50-pound drums of this liquid carbonic gas, and considering the time and expense of handling it, it is out of the question for tire purposes, unless I can recharge them myself. Will you kindly tell me of some way in which to do this at small expense? F. WEHNER.

Frostsburg, Md.

Granting that the gas in the large tanks is at a high pressure, the only caution necessary in transferring it to the smaller drums is that any increase in the temperature will increase the volume of the gas, that is with a constant pressure, while any reduction in the pressure will also increase the volume. The variation in the volume with changes in the temperature is exact and measurable, the variation being .002061 per degree Fahr. above 32 deg. Fahr., the volume at 32 being considered as 1.0. That is, taking the whole volume, each degree rise above the basic temperature will increase the volume by 2-10 of 1 per cent.

Now, if the connection be made from the outlet of the large drum to the outlet (inlet) of the smaller one which is to be filled, through a metal hose, with a valve at each end, the work may be done very rapidly and economically, simply connecting the hose, opening one valve so as to fill the hose, then opening the other and letting the gas expand into the small tank. In case it is desired to fill the smaller tank at a reduced pressure, one of the valves should be a pressure-reducing valve, or both of them may be, the reduction being made in two operations.

Answered and Discussed

Permanent Black Lacquer for Brass

Editor THE AUTOMOBILE:

[2,262]—Recently in the columns of "The Automobile" there was given a formula for making a lacquer for brass work. Now, I would like to know if this lacquer will make a permanent and lasting finish for the bright brass work? I have a Model 10 B Buick with a toy tonneau and would like to have you advise me as to applying this formula to my car, as I get tired of constantly polishing the brass work. In the article in which this lacquer was given, you failed to state how to apply it. LOYD H. JORDAN.

Gordon, Neb.

The lacquer in question is just as permanent as a coat of paint, or of varnish, or any similar coating, which weather, water, acids, and similar substances may wear off, or which will wear off in time, even when protected from these things, that is, in say three years.

To apply the lacquer, the body of the metal to be darkened is cleaned to a dull but very clean surface. Then, the lacquer is applied in a thin even coat with any form of fine brush. In short, it is applied just as varnish would be, except that the unusually quiet conditions and unusual care necessary with varnish is not necessary with this. The greater the care used, however, the better and more satisfactory will be the result.

Since this receipt seems to have aroused quite a little interest, it will be repeated for the benefit of those who missed the issue in which it occurred, namely, March 17, 1910. The two receipts are as follows: Dissolve one-half pound of best pale shellac in one gallon cold spirits of wine (so-called). When the shellac is dissolving, agitate it very thoroughly. After mixing, allow it to stand, then filter and bottle. It must be kept from the light as that would make it darker, this being a light lacquer. Now to make a dead black lacquer or finish for similar work, this may be colored black, or the following receipt may be mixed instead: Fuse three pounds of Egyptian asphaltum. When liquid, add one-half pound of shellac and one gallon of turpentine. The latter formula will give the dead black finish now so popular. The quantity, of course, may be regulated to meet the necessities of the case.

Cleaning Out Troublesome Carbon

Editor THE AUTOMOBILE:

[2,263]—I am a constant reader of "The Automobile" and write to ask that you tell me how I can take the carbon out of my cylinders without tearing them down. They are not so very bad, but I would like to keep them as clean as possible, if there is some way of doing this easily. A READER.

Ellinwood, Kan.

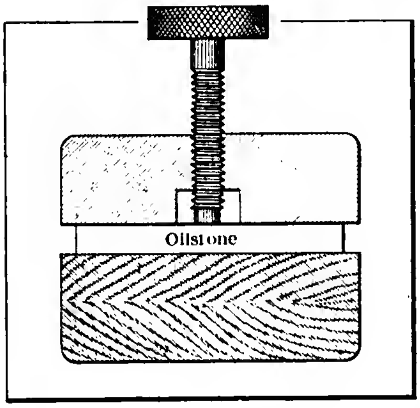
If the cylinders are not very bad, and this is just a matter of having them in the best possible shape, a liquid or powder decarbonizer should do the work very nicely. These are many in number, but the action of all of them is to loosen up the carbon, so that it is blown out by the exhaust the next time the engine is run. Either that or the stuff is dissolved in a liquid which may be drained off from the engine; then when the cylinders have been dried out, the engine is ready to run, and also free from carbon. You will find a number of these decarbonizers mentioned in the advertising columns of THE AUTOMOBILE, and should have no trouble in selecting a suitable one from among them.

Helpful Hints for the Man Who Drives

EVERY amateur should learn to grind in his own valves, for this little job is one that should not be entrusted to every Tom, Dick and Harry who claims to know how to do it. Doing the work oneself, a person is sure that it is done right. This is a job which does not require a great deal of mechanical skill, but on the other hand, it does call for a lot of patience.

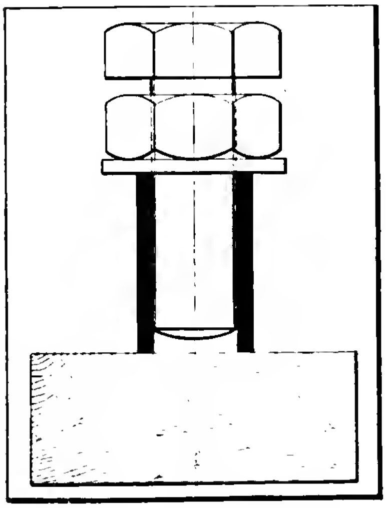
Before grinding the valve must be relieved from the pressure of its spring. In many engines the valve seat and spring are contained in a cage that is easily removed, and the detaching of the spring from the stem is an easy matter. When the valve seat is integral with the cylinder, the spring may be compressed by means of a special tool, or by a flat metal bar used as a lever. The valve may be taken out through the valve opening.

Finely powdered emery mixed with machine oil is a satisfactory abrasive for grinding, but whatever is used, great care must be taken to keep it out of the cylinder and away from the bearing surfaces. The passage between the valve pocket and cylinder should be tightly plugged with cotton waste, a string tied to it facilitating its removal when the work is completed.



Grinding Vibrator Screws Correctly

For a badly worn valve, the first grinding is done with coarse emery, which is later replaced by a finer grade to give the requisite smoothness. To apply the abrasive, dip the finger tip in machine oil and then in dry emery, the small quantity that adheres being applied to the valve surface. The valve is then replaced on its seat and rotated by means of a screw driver. A bit brace or breast drill may be used, but excellent results may be obtained by means of an 8-inch or 12-inch screw driver with a round grooved handle, which is held between the extended palms. A continuous rotary motion in one direction will tend to wear the valve oval, and it is necessary to turn it first in one direction and then equally in the other. A slight back and forth motion of the hands will give this result, and as only a light pressure is necessary, it should not prove tiresome.



Making a Jack on the Road from a Bolt

In order to preserve the true circular form of the valve and seat, the valve should be lifted after twenty or thirty turns, and replaced on its seat in a new position. To facilitate this, a few turns of a helical spring may be placed in the valve pocket under the disc, its size and strength being such that the valve will be slightly lifted from its seat when pressure is taken off.

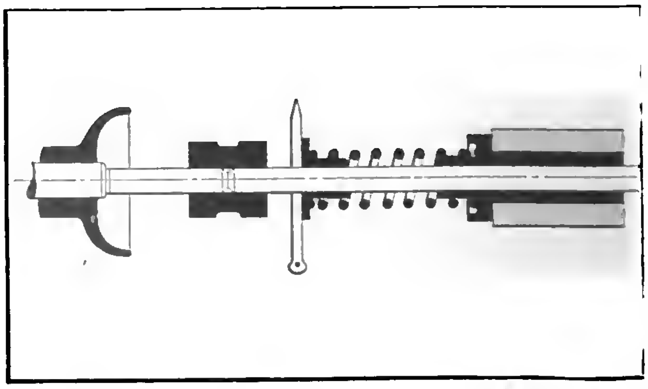
When the valve surfaces appear smooth, all traces of the emery should be washed away with gasoline, care being taken that it does not lodge in the cylinder, valve stem and push rod guides, or other bearing parts. To test the fit, make pencil marks on the valve seat, and give the valve a turn or two with the screwdriver; if the fit is correct the marks will be erased.

The replacing of the valve spring is simplified if it is compressed in a vise and bound in the compressed state by light iron or copper wires passed through it lengthways. The spring may then be placed on the valve stem and the holding device attached, after which the wires are cut.

Grinding valves is quite a nice little trick, but another of equal importance, and requiring even more deftness of band, is the grinding of new points on pitted or worn coil tremblers. A sketch is given herewith showing how this may be done and done right. Take a block of wood with a finished top and set onto or into it a new small oilstone. This should be one of very fine texture. The setting of it into the block is to insure its being perfectly true and level. Then another block should be rigged up so as to set above this, and absolutely parallel to it. In the latter a hole should be tapped the size of the vibrators of the coil. Then to point a vibrator, screw it into the upper block, rub back and forth, or in a circular direction, until the desired result is obtained. The block holding it being square with the oilstone will insure the face being square with the axis.

Very often a motorist gets caught out on the road by some minor accident, some little part breaking, the lack of a repair or supply part for which will prevent the running of the car. Amateurs should carry a good stock of replacements to save themselves the humiliation which comes with this, unless they are possessed of an unusual amount of ingenuity. An example of this is shown in the sketch below. A driver broke the pin in his valve motion which retains the valve spring in place. Not having a spare for this, it was impossible to run the engine without it. With a four or six-cylinder engine, this cylinder could have been cut out, thus reaching home, but in this case the motor has but two cylinders, making the cutting out process practically impossible. Being rather ingenious, the driver hunted through his tool box for something to use in this place, as it was far to the next town. He found he had nothing, not even a wire nail which might have been used, or a cotter pin. Walking along to the next farmhouse, he tried to get something which would answer. After nearly failing, he finally secured a metal meat skewer, which was inserted as the sketch shows, and the engine limped home.

Another stunt was making a jack from an old bolt and nut of large diameter and a piece of scrap tubing. The figure shows how this was done. The tube was set into a block of wood to serve as a base, then the bolt was set on top of that with the nut in place and a washer below it. By screwing the nut down, the bolt-head was raised, carrying with it the load above. This was a bolt of unusually large diameter.



Useful Though Unique Substitute for Valve Stem Key

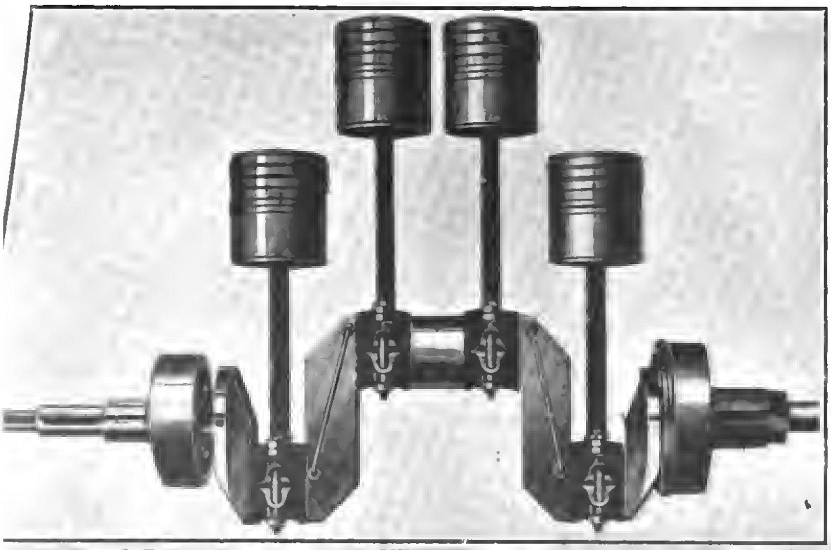
te Gasoline Car Brought Up To 1911

nufacturers to make public the details of the coming year, the White Company has ine of steam and gasoline cars for 1911. will include an unusually wide range of touring cars at $2,000 to trucks at $3,850 at $5,000. As is indicated by the fact that ion has been disposed of, the 1910 models, m, proved eminently satisfactory in every the new models do not show any radical built during the last season. No changes in the prices or in the designation of

all, the engine with which the several es are equipped—no noteworthy change The engine retains those characteristic :e Company introduced a year ago, but ade to bring about a state of refinement the ideals of the company.

e cast en bloc, with the intake and ' within the engine casting. As a re- there are no external manifolds; the their way to the cylinders and, owing st passages within the engine casting may be readily removed without disturbing any other part. In Fig. 1 may be seen a side-plate held in place by two thumb-screws. By removing this side-plate, the valve springs and valve stems are completely accessible. The valves may readily be removed from above, simply by unscrewing plugs located in the upper part of the valve chambers. The Bosch magneto and the centrifugal water-pump are placed on opposite sides of the engine and are driven independently, so that either may be reached for adjustment without disturbing the other. In Fig. 2 it will be noted that the magneto is located on the opposite side of the engine from the carbureter, so that there is no danger of gasoline igniting by dripping on to the magneto, as might happen where both the magneto and the carbureter are placed on the same side of the engine.

The crankshaft is forged of nickel steel and is of unusually heavy construction. As shown in Fig. 3, there are but two main bearings, which are ball bearings of large diameter. A distinctive feature of the crankshaft construction is the arrangement whereby the connecting-rod bearings are positively lubricated. Oil is pumped from the reservoir by way of a sight-feed placed on the dash to oil pipes which are so located that they drip into grooves on each crank-disc, immediately adjacent to the main bearing. These grooves are cut eccentrically with respect to the crankshaft center, with the result that the oil is driven by centrifugal force to that portion of the groove which is farthest from the center of rotation. The oil then passes by means of oil-ways cut through the crankshaft and oil pipes mounted upon it to the connecting-rod bearings. As will be seen in Fig. 3, these oil pipes are mounted eccentrically on the crankshaft, so that from the time when the oil drips into the grooves on the crank-disc until it reaches the crankshaft bearings it is propelled by centrifugal force. By this scheme, the connecting-



ig. 3—Crankshaft of substantial section with a very liberal annular type ball earing at the transmission end, also piping system through which lubricating il is passed to the crankpin journals.

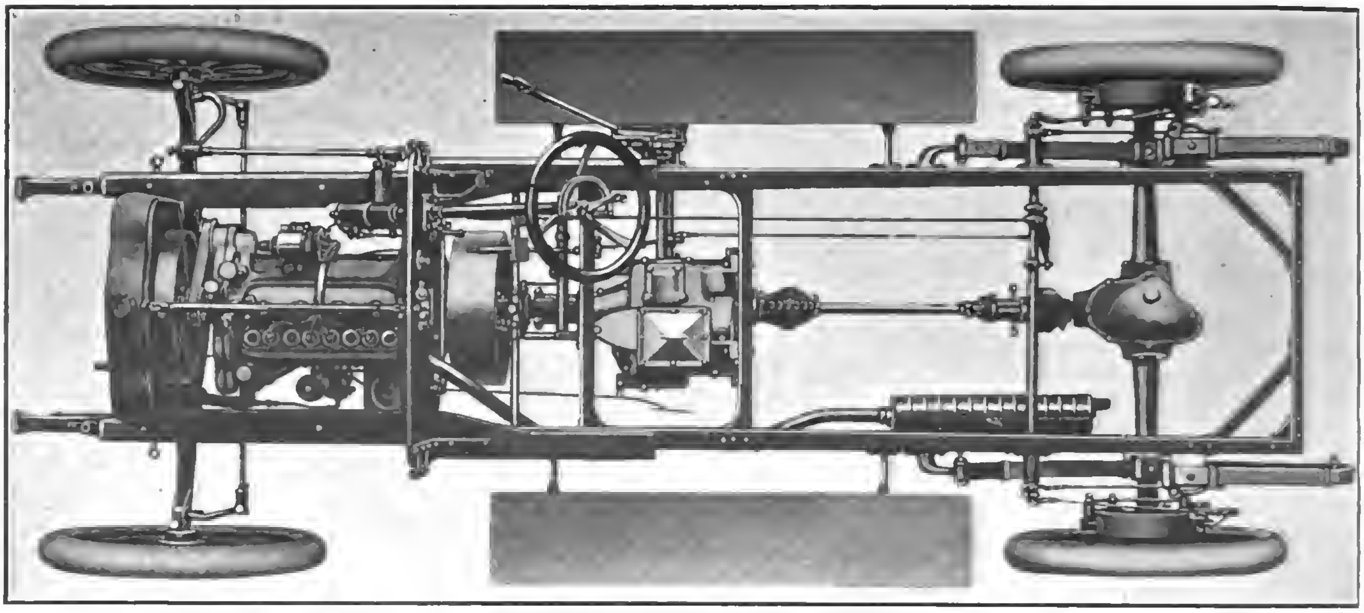


Fig. 4—Looking down on the chassis of Model G-A White Gasoline Car showing the arrangement of power plant, transmission and relating parts, together with size, shape, and bracing of the chrome nickel steel frame of large section.

rod bearings are perfectly lubricated and thus is solved a phase of the lubrication problem, which has caused great trouble to motor-car designers and users.

The crankcase is made in two sections of a special aluminum alloy. The upper section carries all the working parts of the engine. It is hung by three-point suspension on the main frame. The lower section is simply an oil well and is easily removable for inspection of connecting-rods, camshaft, etc., without in any way disturbing the crankshaft bearings. The oil reservoir forms an integral part of the upper section of the crankcase.

Another observed feature of the White construction is the arrangement for relieving the compression in order that the engine may be cranked with a minimum of effort. By means of a small lever located on the dash, the camshaft is shifted endwise, and the exhaust valves are thus held open during the greater part of the compression stroke. As soon as the engine is started, the camshaft is shifted back to its normal position.

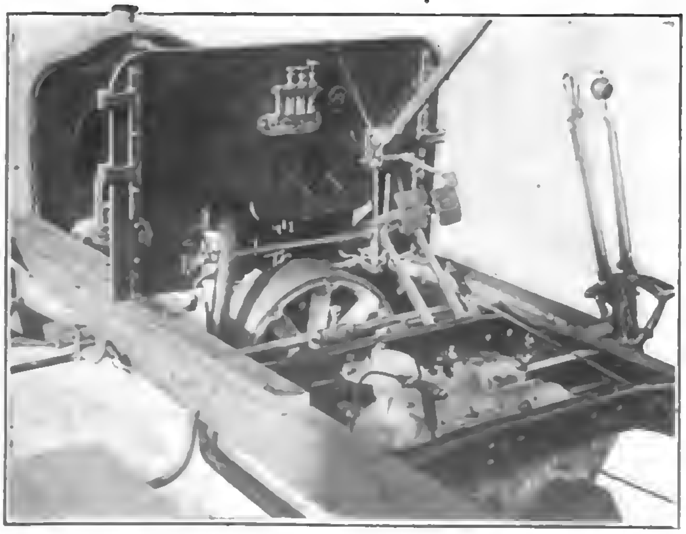

Fig. 5—Showing the dash, control levers and pedals, also cone clutch which is leather faced, employing a special means of holding the leather in the absence of rivets.

The clutch is of the leather-faced cone type, and is of unusually liberal dimensions, giving a working surface as large as is found to be of value. No rivets are used in attaching the leather facing to the clutch spider, the leather being held in place by T-bolts which are countersunk in grooves on the rim of the spider, as shown in Fig. 5.

The transmission is of the selective type and has four forward speeds with direct drive on the third. The gear-shifting mechanism is enclosed within the gearcase and is thus kept well lubricated and free from dirt and grit. A cover-plate, held in place by thumb-screws, may be easily removed, giving access to all parts of the gearcase. The gears are made of chrome-nickel steel and are of unusually liberal dimensions, as regards both width and diameter. The gearcase is located immediately behind the clutch and is supported on cross-members of the frame by three-point suspension. The connection between the clutch and the gearcase is such as to allow for any slight variation in alignment which may occur when the car is traveling over very rough roads.

The drive from the gearcase to the rear axle is by means of a shaft. The rear-axle housing is made in three parts, the central part containing the bevel-gear drive and the differential. This part is fitted with a cover, by removing which ready access is obtained to the gears within. The "live" axle is of chrome-nickel steel. The axle is of the semi-floating type and is fitted throughout with annular ball bearings.

The frame is of heat-treated crucible chrome-nickel steel. In the manufacture of these frames the requisite heat treatment is given by immersing them in baths of molten lead. By this process every part of the frame is raised to the same temperature and, furthermore, the degree of temperature can be absolutely controlled. The frame is narrowed in front of the dash, giving plenty of room to turn the car in the narrowest streets.

The above description applies to each of the two models of the White gasoline car. These two models are known as "G-A" and "G-B," respectively. Model "G-A" has a 110-inch wheelbase, three-quarter elliptic rear springs and 32-by-4 quick-de-

Fig. 6—1911 torpedo type of body with a wide side entrance, unobstructed straight lines, elegant upholstery, and fine finish of all parts of the car

tachable tires. It is fitted either with a 5-passenger touring body with wide rear seat, or with a 4-passenger detachable toy-tonneau body (which may be used in connection with the "domestic-express" body recently described in these columns). It is also fitted with a torpedo body, shown in Fig. 6. With the toy tonneau and torpedo types of body, the steering gear is tuted at a sharper angle than in the touring car and the control levers are in a slightly different position. The model "G-A" touring car and toy tonneau each sell at $2,000 and the model "G-A" torpedo sells at $2,250.

Model "G-B" has a wheelbase of 120 inches, is fitted with three-quarter elliptic rear springs, 34 by 4 tires and, in general, it has a somewhat heavier running gear than the model "G-A." Model "G-B" is fitted with an unusually roomy 5-passenger touring body, selling at $2,500; with limousine body, selling at $3,600; or with landaulet body, selling at $3,800.

The White commercial vehicle line for 1911 will consist of a 3-5-ton gasoline truck, a 1½-ton gasoline truck and a 1,500-pound delivery wagon. Both the 3-5-ton and the 1½-ton trucks were described in these columns several months ago. While the running gears of these three types of commercial vehicles vary widely corresponding with the varying loads for which they were designed, much study was devoted to securing the interchangeability of as many as possible of the parts of the three power plants.

The chassis of the 3-5-ton truck sells at $3,700, the 1½-ton chassis sells at $3,000, and the chassis of the 1,500-pound delivery wagon at $2,100. Bodies for these trucks will be furnished to meet the special requirements of any business.

Moon Pathfinder Takes Trail

St. Louis, May 9—Scouting for the route of the first reliability run of the St. Louis Manufacturers and Dealers' Association, E. Percy Noel, of the Automobile Club of St. Louis, started from St. Louis to-night in a Moon car. He will probably be on the road four or five days in an endeavor to map out the best route for the contestants to follow over the three-day itinerary in Missouri and Illinois. The roads in Missouri and Illinois are in extremely bad condition.

The three-day reliability run is the first real touring event ever planned in St. Louis and it is significant of the tremendous awakening of motor interest in St. Louis that already nearly 100 entries are assured the Contest Committee of the Manufacturers and Dealers' Association in charge.

Stevens-Duryea Changes

Chicopee Falls, Mass., May 9—As a result of a meeting of the directors of the Stevens-Duryea Company, Wednesday, several changes are announced, the most important of which was the resignation of Charles C. Hildebrand, who was general sales manager. Mr. Hildebrand has accepted a position as assistant general manager of the Chalmers Company at Detroit. He has been with the Stevens-Duryea Company eight years.

George S. DeLaney has been made general manager of the company, a new office. He was formerly general superintendent. George Baithwait, factory manager, will continue in his old position and will fill the position of general superintendent also.

Coming Events in the Automobiling World

June 20-July 6...Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 13-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

May 9-11.........Harrisburg, Pa., Fourth Annual Reliability Contest to Atlantic City and Return.

May 10-11........New York City, Reliability Run, Trade Association, New York to Atlantic City and Return.

May 12...........Cheyenne, Wyo., Motordrome, Cheyenne Motor Club.

May 13-14........Denver, Colo., Race Meet, Overland Park. Denver Press Club.

May 14...........Kansas City, Mo., Hill-Climb, Automobile Club of Kansas City.

May 18-19........Norristown, Pa., Third Annual Endurance Run, Norristown to Scranton and Return.

May 19-21........Hartford, Conn., All-Connecticut Reliability Contest.

May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.

May 21-22........Track Race Meet, Memphis, Tenn., Homer C. George, Manager.

May 27, 28-30.....Indianapolis, Ind., Automobile Races, Including Championship Events on Motor Speedway.

May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill; Automobile Club of Bridgeport.

June 2...........New York City, N. Y., Trade Association, Orphans' Day Excursion to Coney Island and Return.

June 4...........Worcester, Mass., Fourth Annual Hill-Climb, Dead Horse Hill.

June 6-14........Atlanta, Ga., Reliability Run to New York City, New York Herald and Atlanta Journal.

June 7...........New Haven, Conn., Hill-Climb up Shingle Hill, Yale University Automobile Club.

June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.

June 15..........Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, Through the Southwest.

June 16-22.......Albany Automobile Club, Albany, N. Y., Sixth Annual Tour to Atlantic City and Return.

June 25..........Port Jefferson, Long Island, N. Y., Hill Climbing Contest. Automobile Club of Port Jefferson.

July 4...........Indianapolis, Ind., Cobe Trophy Race. Held on Speedway Track, Chicago Automobile Club.

July 4...........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

July 18-22.......Milwaukee, Reliability Run, Wisconsin State Automobile Association.

July 30..........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

Aug. 3-5.........Galveston, Tex., Beach Races, Galveston Automobile Club.

Sept. 5..........Wildwood, Pa., Speedway, Labor Day Race Meet of North Wildwood A. C.

Sept.............Chicago Commercial Car Reliability Contest of Chicago Automobile Club.

Oct. 1...........Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.

Oct. 8...........Philadelphia, Fairmount Park Race. Quaker City Motor Club.

Oct. 15..........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 25...........“The American Cup,” Argentina, Sociedad Sportiva Argentina, near Buenos Ayres.

May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.

May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.

June 2-8.........Prince Henry (German) Touring Competition.

June 13-18.......Scotland, Scottish Reliability Trials.

June 20..........French Voiturette Race.

June 21..........French Stock-Car Race.

June 22-July 5...Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.

June 27..........Speed Trials at Kiev, Russia.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

SOMETIMES the feeling is acute as it bears upon the question of the dissemination of engineering information as it comes in from the haunts of designers in many lands. That there is a good deal of duplication is true, but, as a rule, a somewhat different angle obtains, so that light is given, even though it may be in relation to the same subject, but from points of view of the several sets of eyes. It would be impossible to report verbatim the doings from abroad as they are set forth in the several very excellent technical papers there printed, without devoting a whole form to the undertaking. To do this would be to encumber the ideas set forth by the "atmosphere" in which they are placed, which atmosphere, while it is very satisfactory to the readers for whom the papers are primarily produced, is scarcely in keeping with the requirements here and, so it seems, an accurate engineering digest will have the virtue of giving in compressed and comprehensive form, it is hoped, all that can be of any service to American engineers, but it does appear as if the busy engineer should have at his disposal a summary of the ideas which are utilized in other lands, in order that he may be able to determine, by comparison, how much better he is doing than his cousin from afar.

* * *

ACTIVITY as it is found in the several walks devoted to the automobile is nowhere of greater potential value than that which is measured by the automobile clubs which represent the autoist in the many States of the Union. These clubs, while they have a certain social undertone, are therefore for business; they represent the autoist before the legislative bodies; they are the voice which is loud enough to be heard, and they conduct a systematic campaign which is equally to the point. If a lone autoist is landed in a speed trap, it makes very little difference as to whether or not he is fair prey; his voice has too much of the characteristic of a pigmy to penetrate into the soul of the legislator, who is never moved, excepting by a force sufficient in magnitude to overcome legislative inertia. This same lone autoist becomes as forceful as a whole automobile club the very minute he places himself in the ranks thereof and raises his voice in unison with the rest for the good of all. Betimes the lone autoist overlooks the main contention, wants to become the whole thing, but instead becomes a nuisance. There can only be one president to any club, and he serves, if he serves well, as the trumpet which sounds the battle cry of the corps as a whole. The rank and file of the club is just as much a recognized necessity as the official who occupies the apex of the cone, and it is extremely important that he take the brunt of a real fight backed by the strong arm of real fighters, rather than to be the leader of a flock of geese. Fortunately, there are mighty few flocks of geese with the crest of an automobile club to mark their abiding place, and due to the wise action which is taken by the conservative automobile clubs in the several States, legislation, as it relates to the automobile, is taming down.

* * *

ADMITTING that the tire problem has its many important phases along lines which include the questions of quality and cost, assuming that these phases must be dealt with by serious-minded captains of the industry, even so, there are other angles from which the problem must be viewed, and in relation to which something must be done. It is well understood that every tire turned out of even the best equipped establishment devoted to the purpose cannot be up to the high standard set by tire makers for their product, and the part of the tires which fall below this standard are labeled as "seconds." The culls of the plants may be very good, indeed, but if the makers are unable to conscientiously imprint their name upon the seconds, and if they are sold through roundabout channels, ultimately reaching the users of automobiles, will it not be fair to all concerned if these same tires are sold as seconds? If so, why should the dealers in seconds be permitted to obscure the fact in any way whatsoever, in or out of advertising, to the end that owners of automobiles will go away after having purchased such tires with the understanding that a bargain fell their way, and that they were so fortunate as to be able to get more for the money than could be had through normal channels? Would it not be quite right were the tire makers to insist upon it that seconds should be sold as seconds, and as seconds only?

* * *

SPRING time comes along bringing better weather and with it better roads, the impression begins to take hold that now is the time for touring the country. So, it is that an increased number of tours and endurance runs are scheduled for the coming month. These partake of all different methods of testing out the new cars, and as such, have, each and every one of them, a direct and favorable influence upon the automobile business as a whole.

New Stock Car Rule Jeopardizes Prizes

CONSIDERABLE comment has been aroused in motordom over the new rule of the A. A. A. which requires that a "stock-car" certificate shall be filed with that body by the manufacturer before stock-cars made by the concern can compete in any event under sanction of the A. A. A.

All the necessary blanks were sent out to the various manufacturers last March, but the returns have been less than half so far.

Some little uncertainty has arisen as to the possibility of enforcing the rule and the intention of the A. A. A. to require its rigid enforcement, but these ideas are without solid foundation.

Chairman S. M. Butler of the Contest Board in commenting upon the situation said: "The conditions are simply these: The greatest line of progress in motoring this year is the proper classification of the stock-car. It is manifestly unfair to the public and to manufacturers who enter bona-fide stock cars in racing and touring events, to have specially made and prepared cars, masquerading as real stock cars, contesting against the legitimate entries.

"For that reason, the present rule was framed and, under it, every manufacturer is obliged to file a detailed certificate showing the standard of the stock cars turned out by him. In case such certificate is not filed, not only is the manufacturer barred from entering his cars under A. A. A. sanction, but agents and private owners are similarly barred.

"Supposing that the maker does not care nor intend to race or tour in competition, and fails to file his certificate, he probably will find that his action has worked a hardship upon agents and representatives who do wish to take part in competitive events.

"In the Around New Jersey Reliability Run which started Tuesday there were thirty-one cars to start and twenty-two of them were made by manufacturers who have not yet filed their certificates. As it would have ruined the run if these cars had been barred from starting, the rule has been modified to a slight degree. The cars mentioned were allowed to start only under the condition that the entrants would notify their factories by wire immediately, requesting that the certificate rule be complied with at once and upon the express agreement that no matter where they finished in the run, there would be no participation in the prizes or awards unless the necessary certificate was so filed.

"While this slight modification was made for this event, in future unless the certificates are on file before the start of the run, the cars will not be allowed to take part under any condition, even though it means the abandonment of the event."

Mr. Butler said that he believed the twenty-two manufacturers interested in the Around Jersey tour would file their certificates at once.

The rules in relation to stock cars as promulgated by the "Contest Board," were published in THE AUTOMOBILE in the issue of March 3, but for the benefit of those who may not have followed the plan closely, that part of the rules which relates particularly to stock car conditions is repeated briefly as follows:

Stock Car—"A motor car, the complete description of which, upon the official blank provided for the purpose, has been filed with the main office of the Technical Committee of the Contest Board at least 30 days prior to the date of the contest entered, the quantity production of which bears to the total yearly production of its manufacturer the ratio set forth in the following table, and which is on sale through the regular selling representatives of the manufacturer."

Official blanks for stock car description may be obtained from the chairman of the Contest Board, 437 Fifth avenue, New York City.

Computation in connection with the following table shall be based upon a period of time from July 1 to June 30 the following year.

In computing the annual output of a manufacturer, no account shall be taken of his production of taxicabs, delivery wagons or other vehicles designed for commercial use.

At the discretion of the Contest Board any competitor may be required to file a bond of $5,000 that the entry made by him is a bona fide stock car within the meaning of this definition:

Total Output.	Percentage.		Number of Same Model.
10,000 or more	4.5%	equaling	450 minimum
8,000 to 9,999	5.0%	equaling	400 minimum
6,000 to 7,999	6.0%	equaling	360 minimum
4,000 to 5,999	7.0%	equaling	280 minimum
2,000 to 3,999	8.0%	equaling	160 minimum
1,000 to 1,999	9.0%	equaling	90 minimum
500 to 999	10.0%	equaling	50 minimum
250 to 499	16.0%	equaling	40 minimum
100 to 249	30.0%	equaling	30 minimum
50 to 99	50.0%	equaling	25 minimum

Explanation—Percentages are calculated on actual total output For example: If the total annual output of a manufacturer is 2,500 cars, at least 8 per cent. of said output, or 200 cars, must be of the same model in order to constitute such model a stock car under this definition. The required percentage of output shall in every case be in accordance with the above table and in no event shall it be fewer than 25 cars.

National Association of Manufacturers Meet

The fifteenth annual convention of the association will be held May 16, 17 and 18, inclusive, at the Waldorf Astoria, New York City, and among the extremely important matters which will be discussed will be the prevention of accidents and employers' liability insurance. This important matter has been before the association on former occasions, and despite the struggle which is ever going on to arrive at a satisfactory basis, it is still an open question, and this year the association will undertake to establish a working basis for the future. The question of appliances for preventing accidents to working men and accident indemnity is regarded by the association as its most vital question, both from an economical as well as a humanitarian standpoint. The committee in charge expresses the hope that the convention will be fully attended, and it points out that those who fail to put in an appearance will miss an opportunity to participate in one of the greatest, if not the most interesting, discussion that has come before any of the conventions of the association. The keen interest shown by the association is best evidenced not only by the personnel, but by the vast amount of work done.

John Kirby, Jr., president of the N. Ass. of Mfgrs., Dayton, O.: James W. Van Cleave, president of the Bucks Stove & Range Co., St. Louis; D. A. Tompkins, president of D. A. Tompkins Co., Charlotte, N. C.; H. E. Miles, president of Racine-Sattley Co., Racine, Wis.; Henry B. Joy, president of the Packard Motor Car Co., Detroit, and F. C. Schwedtman, of St. Louis, chairman.

Hopes for Federal Registration

At the regular monthly meeting of the Executive Committee of the A. A. A., presided over by President L. R. Speare, and held Tuesday morning, at National headquarters, 437 Fifth avenue, it was made clear through the report of Chairman Charles Thaddeus Terry that the Legislative Board hopes to have its Federal Registration bill emerge from committee at Washington, D. C.

To-day Chairman Terry will go to the Capital where he will meet the delegates from the Chicago Motor Club, which has in charge the petition containing over 5,000 names, secured in the district from which Congressman Mann hails, he being the chairman of the Interstate and Foreign Commerce Committee, which has had the measure in charge. With the petition will be presented the consensus of opinion of the Chicago legal talent to the effect that the proposed law is constitutional.

From Governor T. M. Campbell, of Texas; Mayor S. J. Hay, of Dallas, and the Board of Trade of the latter city, came an invitation to Chairman S. M. Butler, of the Contest Board, that the Glidden tour visit Texas, and in particular the city of Dallas. Pathfinder Lewis has included the Lone Star State in the route, and he is now touring through Kansas. The entry list, at regular fees, will close May 15, with present indications that this year's contest will exceed all predecessors in point of entries, because much of the country traversed is virgin soil for automobile manufacturers.

Ground Broken for Lozier Factory in Detroit

DETROIT, May 9—Contracts have been let and ground is being broken for the Lozier Motor Co.'s $2,000,000 plant in St. Clair Heights, an eastern suburb of Detroit, and the Hudson Motor Car Co.'s new $500,000 factory in the Fairview district. These are but two of the large plants for the manufacture of motor cars and auto parts now in the course of construction in this city, all of which will be in operation before the end of the year.

Considerable speculation is going on as to why work has not started on the General Motors plant, for which a site was purchased several months ago and which, it was announced, would mean an expenditure of $2,500,000. It is understood, however, that plans are being prepared and that bids will be asked soon.

In the vicinity of the future Hudson plant, 400 men started work this morning, breaking ground for the Anderson Forge & Machine Co.'s new drop-forging plant, which will cost $750,000 and will be the largest plant of its kind in the world, it is claimed. Automobile crankshafts form a large part of the company's output.

The Modern Machine & Engineering Co. has removed from Cleveland to Detroit, with offices in the Ford Building. This company handles the Potter & Johnson line of automobile machinery, which is used extensively in local car factories. Thomas F. Ahern, general manager of the company, has found it necessary to spend the greater part of his time in Detroit for the past two years and for this reason it was decided to remove the headquarters here permanently.

The plans for the new Hudson plant, the contract for which was let to the Andrew J. Smith Construction Co., call for a main building, an office building, a testing building, a power house, shipping sheds and a dining hall. The plant will cover 2.8 acres and will have 223,500 square feet of floor space. The main building will be 580 feet long and will have two wings, each about 300 feet long.

In acordance with the action taken by the new directorate of the E-M-F. Co., immediately following its recent purchase by the J. P. Morgan interests, work is about to start on extensive additions to the company's main plant on Piquette avenue. Negotiations for the purchase of the necessary land adjoining the present buildings, which have been in progress for several weeks, were closed last Friday.

It is reported that the Simplex Motor Car Co., of Mishawaka, Ind., makers of the Amplex car, have purchased a factory site along the proposed extension of the Detroit Terminal Railway in Greenfield Township, immediately north of Detroit.

The Beyster-Detroit Motor Car Company, capitalized at $50,000, has filed notice with the County Clerk of Wayne County, Mich., to increase the capital stock to $250,000.

Chicago Floral Parade Included 120 Automobiles

CHICAGO, May 10—Forced by the rain to postpone its first annual floral parade from Saturday to Monday, the Chicago Automobile Trade Association succeeded in pulling off a most creditable affair in which 120 motor vehicles ranging from big 5-ton trucks down to motorcycles and including a fair representation of owners competed. Undoubtedly the postponement had its effect upon the parade, for more than 100 cars which had been entered were scratched principally because their owners were unable to participate because of business reasons. However, so far as the general public is concerned these defections did not hurt the parade in the least. All the cars were handsomely decorated with natural and artificial flowers, and all along the route which took in 30 miles of Chicago's boulevards there were crowds of people all of whom evinced a lively interest in the affair. The city of Chicago did its best to help matters along by sending a detail of motorcycle policemen as an escort while the Chicago Association of Commerce showed its power in the commercial section, which was fairly representative of Chicago's business strength in the commercial motor world. The judges of the affair were prominent cartoonists and artists including T. M. Wilder of *Motor Age*, L. D. Bradley of the *Daily News*, C. A. Briggs of the *Tribune*, Ralph Wilder of the *Record-Herald*, and J. G. DeLong of the *Cherry Circle*.

These judges lined the cars up on the midway and made a critical examination of the decoration from their artistic viewpoint. They decided that the best decorated car was an Oldsmobile entered by the local branch which was decorated in Clemantis. The car best decorated in natural flowers was an Alco belonging to a private owner, D. J. Joice, who spent nearly $500 for American Beauty roses. The best float was declared to be a Maxwell, which carried the Scottish bag pipers and was decorated in Scotch colors. In the private owner's class Mrs. Harry McKeller carried off the cup with her Winton car which was decorated in poinsettias, the deep red flower from California. The best electric was the Detroit driven by Miss Yetter which appeared to be propelled by the silent energy of two huge butterflies.

It is the intention of the Chicago Automobile Trade Association to make this event an annual affair and next year it is anticipated that it will be easy work to get more than 500 cars out for the demonstration. This year's parade was ably handled by a committee consisting of John H. Kelly. Henry Paulman and O. G. Temme which went about the organization, as a demonstration, in a business-like manner sending out more than 10,000 letters in its attempt to arouse the motorists of Chicago to the benefits to be derived from participation in the event.

J. D. Maxwell Is Now President

J. D. Maxwell, who has been vice-president and general superintendent of the Maxwell-Briscoe Motor Company, has been chosen president of that company, following the resignation of President Benjamin Briscoe, who assumed the presidency of the United States Motor Company.

For seven years the name of Maxwell has been familiar to those interested in automobiling and J. D. Maxwell has been looked upon as a pioneer and designer of exceptional ability.

All in Readiness for 24-Hour Race

With automobile racing a little slower in the East than elsewhere this Spring, interest in the big twenty-four hour contest which will be decided at Brighton Beach Friday and Saturday, is centered upon the event. Special preparations have been made to accommodate vast crowds and numerous improvements in the course itself and its conveniences have been installed.

Those who have been closest to the project say that the record this year will probably exceed 1,200 miles.

News of the Philadelphia Automobile Trade

PHILADELPHIA, May 9—At a meeting held in the Odd Fellows' Temple last Wednesday afternoon the Philadelphia Licensed Automobile Dealers' Association effected a permanent organization, electing the following officers to serve during the ensuing year: President, J. A. Wister, of the firm of Gawthrop & Wister, Elmore agents; vice-presdent, E. B. Jackson, of the local Packard company; secretary-treasurer, W. J. Foss, of the Foss-Hughes Motor Car Company, Pierce-Arrow agents. These gentlemen, with A. E. Maltby, manager of the Winton branch, and W. C. Longstreth, of the Pullman agency, constitute the Board of Governors. A constitution and by-laws were adopted and a committee composed of Messrs. Hipple (Chalmers), Jackson (Packard), Smith (Maxwell), Shelden (Premier) and Longstreth (Pullman) was appointed to secure at once a charter for the organization.

The Haynes Auto Company, now located at 211 North Broad street will move to "Marble Row," 326 North Broad street about May 15. The new building is double the size of the present quarters.

Walter S. Shawvan, of Chicago, has signed to manage the sales department of the Stoyle-Vogel Auto Company, distributors of the American for Eastern Pennsylvania, New Jersey, Delaware, Maryland and the District of Columbia. Mr. Shawvan comes here direct from the Boston Packard branch.

H. Leslie Walker has joined the sales force of the Hills Motor Car Company, which handles the Royal Tourist in this city.

Some idea of the phenomenal growth of the automobile in Pennsylvania may be had from the figures issued by the Automobile Bureau of the State Highway Department for the first four months of the present year. Last year the total number of licenses issued was 34,351. Up-to-date the number of 1910 credentials passed out has been 38,970, made up of 22,909 owners, 11,185 chauffeurs, 2,150 dealers, 374 special and 2,352 motorcycles.

George B. Blind, who has been connected with the automobile business in Philadelphia since 1900, has just taken the local agency for the Black Crow car, with headquarters at 2117 North Broad street.

The Regent Garage, one of West Philadelphia's largest automobile storage plants, Fred K. Mears, proprietor, has just installed a charging plant for electric vehicles. It was formerly necessary to run his electrics into the center of the city.

While the treasuries of the various boroughs and townships involved are suffering not a little as a result of this disinterested labor on the part of the Delaware Countians, and the rake-offs of the bucolic Vidocqs have been reduced almost to the vanishing point, motorists hereabouts, attached and unattached, are in high feather, and are showing their appreciation by helping along the work all they can. A notable increase in the membership of the A. C. of D. C. may be ascribed in large part to systematic warning work now carried on by the club.

Swann Law Is in Effect

BALTIMORE, May 9—The new Swann Motor Vehicle Law is now in force, Commissioner of Motor Vehicles John E. George having assumed office last Monday. He has given a contract to the Auto Supply Company for 5,000 sets of automobile tags, there being two tags to each set, and 500 motor bicycle tags. The automobile tags have blue letters on a white background. According to the new law all cars in the State must have tags before July 1.

Pioneer Manufacturer Is Dead

. V. Becker, one of the pioneers of the automobile industry, May 3 at his home in Clyde, O. He was 84 years old, until recently took an active part in business with the El- company. Mr. Becker was the father of B. A. and J. Becker who were associated with him.

Mosler Company Enjoys Show

R. Mosler and Company, makers of the Spitfire spark plug, tained the employes of that concern with a theatre party Thursday night. The play was the "Spitfire" and was given e New Lyceum Theatre. About 250 constituted the party occupied the balcony of the show house.

Boston Branch for Remy Magneto

Remy Electric Company of Anderson, Ind., manufac- of the well-known Remy magneto, have opened a branch outing office at 214 Pleasant street in the Motor Mart, . The office will be in charge of M. H. Pearson.

Touring Club Entertains

Touring Club of America entertained representatives of etropolitan press at luncheon Monday. The function was tended. Many prominent speakers were heard.

S. A. E. Gets Coker F. Clarkson

At a meeting of the board of the Society of Automobile Engineers which was held in New York City, on Tuesday, all the formalities leading up to the engagement of Coker F. Clarkson were completed, and he is now in charge of the work of the society. That Mr. Clarkson will have a busy time of it for some months to come, is assured, and it is the aim of President H. E. Coffin to advance the work at a rapid rate. There are many obstacles to be encountered and overcome, and it was the purpose of the society to obtain the services of a secretary who would be able to make headway which is the reason why Mr. Clarkson was approached. The society is to be congratulated in having succeeded in its endeavor to procure the services of so capable a man.

H. A. Bonnell, who has been treasurer of the A. A. A., has been elected assistant general manager of the A. L. A. M. to succeed Coker F. Clarkson. Mr. Bonnell was for several years secretary of the New Jersey Automobile and Motor Club of Newark.

Trade Association Shows Growth

Four new members have been elected to the New York Automobile Trade Association. They are: Rothschild and Company, Fisk Rubber Company, Thedford Auto Garage, and the Correja Motor Car Company. The roster of the association now includes 75 concerns. The addition of numerous garage concerns to the association has led to the abandonment of the idea of the formation of an organization composed of garages exclusively. New quarters have been secured at 1777 Broadway.

Will Entertain Little Cripples

Wyckoff, Church & Partridge, New York representatives for Stearns cars, have planned to give an outing for the pupils of the Free Industrial School for Crippled Children, located in West Fifty-seventh street, Tuesday, May 17.

The trip will be to Coney Island, where the little ones will be given the privileges of the various attractions at Dreamland.

Pathfinder Crossing Madison Creek at Ford City, Okla.

Sometimes Railroad Tracks Furnish Better Going Than the Highways

Iowa Farmers Royally Greet Pathfinder

THE 1910 Glidden Tour will be about 2,800 miles long, according to the latest estimates. The change in the route to include Omaha has added the extra mileage to the original plans. In another respect it will be an unusual event. The route of the fourteenth day of the run, which will be from Kansas City to Omaha, will be 242 miles long, the biggest ever essayed in a single day by the Glidden itinerants.

This day's run will be over Iowa roads, as the former intention of traversing the route to Omaha on the west side of the Missouri River has been found impracticable. In one way, the change has proved surprisingly favorable, for reports received from the pathfinding party show that three clubs have been formed in the rich Iowa bottom lands to be traversed by the tour. As a matter of fact the pathfinding has been very effective in stirring up interest in automobiling all along the way and at least a dozen automobile organizations have sprung into life while the scout and his party have been passing.

The territory included in the route of the tour this year amounts to about 1,000,000 square miles, in which over one-third of the population of the United States dwells. Nearly 200 incorporated cities having a population of upward of 5,000,000 are touched by the map of the tour. The official map of the event as far as it has been determined up to Tuesday is as follows:

	Miles
1st Day—Cincinnati to Louisville	162
2nd Day—Louisville to Nashville	193
3rd Day—Nashville to Sheffield	119
4th Day—Sheffield to Memphis	161.7
5th Day—Sunday in Memphis	...
6th Day—Memphis to Little Rock	207.7
7th Day—Little Rock to Texarkana	191.6
8th Day—Texarkana to Dallas	217.1
9th Day—Dallas to Lawton, Okla	200
10th Day—Lawton to Oklahoma City, Okla	145
11th Day—Oklahoma City to Wichita	216
12th Day—Sunday in Wichita	...
13th Day—Wichita to Kansas City	234
14th Day—Kansas City to Omaha	242
15th Day—Omaha to Des Moines, Iowa	160
16th Day—Des Moines to Davenport, Iowa	190
17th Day—Davenport to Chicago	200

DES MOINES, IA., May 11—Almost like a triumphal procession of royalty was the progress yesterday of the Glidden 1910 Pathfinding Chalmers car from Omaha to this city. The roads were in almost perfect condition, having been worked over with split-log drags just prior to the passage of the official party, and as this section of Iowa is one of the richest and most prosperous agricultural sections of the land, where the automobile is the valued possession of a big percentage of the farmers, the visit of the pathfinders is appreciated and prized in extraordinary degree.

The route from Omaha to Des Moines is 159 miles and will constitute a day's run of the tour proper. The rest of the distance across the State to Rock Island is also in perfect shape.

Carnival to Open New Elgin Course

CHICAGO, May 9—Inside the next week it is expected the Chicago Motor Club will make application to the A. A. A. for a sanction for a road race carnival to be run this Fall at Elgin, Ill., 38 miles from this city. It looks now as if it would be a two-day meet with a small-car event for an opener and the big race on the second day. Negotiations with this end in view have been in progress for some time, and matters were brought to a focus last night when the citizens of Elgin decided to form the Elgin Automobile Road Race Association and to incorporate under the laws of Illinois with a capitalization of $20,000.

This means that Elgin will finance the races and that the Chicago Motor Club will organize and run the contests. All that remains to complete the deal is the formal meeting of the two organizations when the agreement will be drawn up and signed by both parties.

Considerable preliminary work has been done already. A committee of Elgin citizens has visited the owners of property surrounding the course and has secured the written consent of three-fourths of the thirty-eight property owners, while the remainder have given verbal promises to permit the use of the roads for racing purposes. This deal is unique in motoring annals, in that the farmers are partners in the enterprise, the Elgin association which is financing the deal having agreed to give each farmer 33 1-3 per cent of the sale of tickets for viewpoints on his premises.

The course the promotors have in mind is regarded almost ideal for racing purposes. In shape it is an irregular pentagon with two long strips of about equal distance, a connecting one mile strip at its western end and a short stretch on the east which almost makes it a hairpin at that end. The surface of the road is stone the entire distance around and there is only one place where there is any suggestion of a grade.

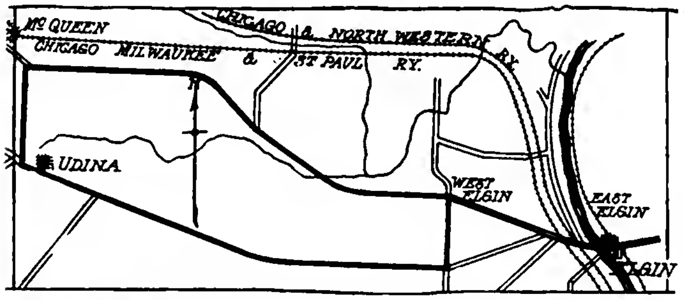
As it stands now the roadbed is 14 feet wide and almost a boulevard in smoothness, but in addition to this there is 1 foot on each side of the visible roadbed that is of the same stone formation, but covered by grass. In addition to this there is a side dirt road with no appreciable drop from the main highway.

There are three bridges on the course. One is of stone and iron; about one-third of the way down the north leg it is 28 feet in width. The other two are wooden bridges and as wide as the road itself. Outside of the four turns, each of which is a four corners, there is not a highway crossing the course, and but two roads lead into it, one on the north leg and the other on the south. Probably sixty buildings are scattered around the circuit representing thirty-eight property owners. The course is 8.4 miles around.

At present the circuit needs some attention, although not very much. There is some loose gravel on the road which must be removed, and the south leg is dippy. However, an expenditure of $8,000 or $10,000 for scraping and oiling should make the course one of the fastest, if not the fastest, in the country.

In the map below. the actual layout of the course may be seen, as well as the straightaways and the nearness to cities.

Chance for Speed on Elgin Course, After Rounding the Hairpin



Map of Elgin Circuit, Which Chicago Motor Club Will Use

Willys Overland "Thirty" To Be Tested Out

FROM New York to the "coast," by a route which will cover upwards of 3,500 miles, is the distance which a regular stock Overland "thirty" will have to make, and what is equally to the point, the car is to be driven for the whole distance by a woman, Miss Blanche Scott, who hails from Rochester, New York. The idea of the Willys-Overland Company, of Toledo, O., is to furnish an object lesson to the women of America; a lesson in fact that will answer for all time. There have been various kinds of tours from coast to coast, but they were handled on a basis such as lent the impression that it was a very grave undertaking, and special cars were frequently used for the work. Then, the drivers were heralded as "dare devils," ready for a fight or a frolic as the weather might seem to indicate.

The belief is that a well made car may be piloted from coast to coast with about the same facility that it may be driven from New York City to Buffalo, Boston or Philadelphia, excepting that the distance is enough to try out the staying qualities of the automobile, and it is admitted that some of the roads will be hilly, soft in places, and capable of taxing the power plant of a good automobile. This is not a matter which should be viewed with great alarm by the maker of any automobile which may be regarded as abreast of the times, but the run will serve as a proof of the pudding, so to speak. It will also tell the ladies that the time has arrived in the world of automobiles when they need have no fears or qualms.

For the most part the route will be in accord with the "surveys" as made by the topographical engineers who did the work for THE AUTOMOBILE BLUE BOOK and in a general way as follows: Starting from New York, north along the Hudson river to Albany, thence west, touching Syracuse, Rochester, Buffalo, Cleveland, Toledo, Chicago, Milwaukee, Cedar Rapids, Des Moines, Council Bluffs, Omaha, Hastings, Julesburg, Denver, Cheyenne, Laramie, Rawlings, Rock Springs, Granger, Ogden, Tonopah, Goldfield, Beatty, Kelly's Well, Cajou, Los Angeles and San Francisco.

From New York to Ogden the route follows beaten paths, but west of the Great Salt Lake the car will traverse a desert that will test its quality. The southwest trip through Nevada will undoubtedly prove interesting enough and even in the present advanced stage of motor construction it would furnish a test which will have to be regarded as up to the most strenuous requirement from the stock car point of view. It will be remembered that the Model 38 Overland sells for $1,000; this is an interesting phase of the problem; it emphasizes the advance which has been made in automobile construction in the last few years, and, in all truth, were it not for this angle, together with the fact that a woman is to make the trip, the undertaking would have little or no interest for autoists. This, however, makes a vast deal of difference, showing as it does indirectly, the simplicity of control of the machine in question.

Herald-Journal Pathfinder Starts

In a big Columbia touring car, the pathfinding party of the New York *Herald*-Atlanta *Journal* road tour scheduled for next month, started from Herald Square Saturday. The party consists of James Rolfe, driver; L. M. Bradley of the United States Motor Company; a representative of the *Herald* and N. Lazarnick, official photographer.

A big crowd gave the pathfinders a send-off on their long trip. The run to Philadelphia was without special incident, but some bad roads were encountered this side of Gettysburg. Reports from the roads ahead are all more or less favorable and a splendid trip is predicted for the party. Much interest has been aroused through the South.

Special Speedway Trophy, Atlanta

K. C. Hill Climb

KANSAS CITY, Mo., May 9—There are 22 entries in the annual hill climb of the Automobile Club of Kansas City May 14. Dodson Hill is being put in faultless shape by the County Highway Engineer, R. T. Proctor, and all necessary arrangements for a successful meet have been made by P. M. Stevens, secretary of the club and representatives of the A. A. A.

A. A. A. Rules Govern Norristown Run

White-winged peace has settled down upon the tentative battle ground of the Norristown Automobile Club and the Contest Board of the A. A. A. When the rules for the coming reliability run of the Norristown club to Scranton and return were framed, the club injected several innovations to fit local conditions that were at variance with the road tour rules of the national organization.

One of these was a change in the classification of the cars entered of about $100 in each class and another rule provided for the entry of toy tonneaus in the touring car class, while another required a brake test backward on a ten per cent grade.

These rules were all promptly blue-penciled by Chairman Butler and red war was threatened on the part of the club. But chief among the demands of the Norristown organization was a rule to prevent scorching between controls and in that respect the club was successful in gaining recognition. At one time the direct ultimatum was delivered by the club that it would run its tour without sanction unless its rules were confirmed, but the diplomatic appeal of Chairman Butler to the sportsmanship of the club turned the tide in favor of peace.

A. L. A. M. Threshing Out Tire Problem

One of the largest meetings of the board of managers of the A. L. A. M. ever held, assembled Wednesday at the headquarters of the organization to consider the problem of tires for the 1911 output. The present level of rubber prices and the impossibility of tire makers to buy at current rates and supply their product to the automobile manufacturers at the figures of last year, were two of the subjects discussed at the meeting. The rubber corner was thoroughly treated from every viewpoint and its causes and probable effects were considered.

The Detroit contingent arrived in New York Tuesday morning and a series of conferences, held at various hotels, tended to promote an understanding between the manufacturers before the meeting was called.

Atlanta's Epochal Spring Meet Ends

(Continued from page 871.)

THERE were a number of accidents on the opening day, but not any on the later days, with the exception of some minor changes in the way of substituting one engine for the power plant of another car, both of the same make, etc.

Three-Day Minnesota Tour

The second annual reliability run of the Minnesota State Automobile Association will go this year to Aberdeen, S. D., and the pathfinder, a five-passenger E-M-F car will start out over the route May 9.

Dr. C. E. Dutton, of Minneapolis, chairman of the contest committee, will go with the car. The main trophy, that offered by the St. Paul Dispatch, is now in possession of the Minneapolis club and will be competed for again this year.

Last year the total entry was seventeen contestant and half a dozen non-contestant cars, while local cars along the route to Fargo and return joined in. Governor Eberhart may enter the run.

Club May Use Indianapolis Speedway

INDIANAPOLIS, May 9—An automobile club is being organized in Indianapolis by private owners, dealers and manufacturers, and an effort is being made to obtain 1,000 charter members at a membership fee of $15. Carl G. Fisher, president of the Indianapolis Motor Speedway Company, has agreed to build a club house at the Speedway grounds and to allow members access to the Speedway course for pleasure driving. The club will be separate from the association organized recently which affiliated with the American Automobile Association. The committee on organization is composed of F. I. Willis, A. R. Kling, T. E. Hibben, Frank Staley and Charles A. Bookwalter.

Many Cars for Orphans' Day

Responses came promptly in answer to the appeals and entry blanks sent out for cars for the Orphans' Automobile Day. E. Lascris, manager of the De Dion Bouton Selling Branch, made the first entry of two cars, this being followed by two National touring cars by the Poertner Motor Car Co. The Maxwell-Briscoe Co. offered 20 cars and one Grabowsky truck, which will carry 60 children. This was followed by an offer from Manager George W. Bennett, of the White Co., for two big White gasoline trucks accommodating 80 children.

1910 Touring Information for Automobilists

(Continued from Page 877.)

The surveys are much more complete, comprehensive, the style is brief and terse. The type is large and clear, so that it will be possible to open the book while riding in a car, turn to the part which gives the information desired, and readily read the instructions and directions, even under conditions of great disadvantage. This particular book also includes routes in the Provinces of Quebec and New Brunswick, and directions for getting in and out of New York are also given their proper spacing. There is one other point, the consolidation of the Red Book with the Blue Book adds materially to the comprehensiveness of the latter, in that it includes all worthy information which formerly obtained in the Red Book proper. The Official Automobile Blue Book is published by The Automobile Blue Book Publishing Company, 239 West 39th street, New York City.

Trophy for 200-Mile Event, Atlanta

Medals for Drivers

CHICAGO, May 2—Following up its offer of the Chicago trophy for the roadster division of the Glidden tour, the Chicago M. C. has decided on another innovation—a gold medal to the winning driver.

AMONG THE GARAGES

William G. Grieb, new president of the Ajax-Grieb Rubber Company, Trenton, N. J.

Regal Plugger, which is making a tour of the principal cities of the country, stopping to ask road directions

Haney-Pistor Co., of Kewaunee, Wis., is building a large public garage, the first in Kewaunee.

A two-story garage and office building is being erected at Fond du Lac, Wis., by J. L. Remington and R. H. Lee.

An electric automobile garage has been opened at 2174 East Ninth street, Cleveland, by Clarence A. Downey.

Park Automobile Company, of Johnstown, Pa., has opened its new garage on Locust street. Floor space for fifty cars has been provided.

The Russell Garage at Berlin, Wis., was almost totally destroyed by fire on May 5. Several other adjoining buildings were badly damaged.

P. J. Needham, agent for the Columbia and Maxwell at Scranton, Pa., is about ready to move into his new garage in Wyoming avenue.

Dusseau Motor Car Company, of Toledo, O., was incorporated with a capital stock of $30,000 to conduct a sales agency and garage in Toledo.

L. De Stwolinski, manager of the Central Garage of Fort Scott, Kan., announces that his concern will occupy one of the new buildings at First street and Scott avenue next week.

Quarters for the Auto Sales Company's garage at Lynchburg, Va., will be located on Main street and will be ready for occupancy this month. The garage can take care of twenty-five cars.

Florida Automobile and Gas Engine Company, of Tampa, is building a garage 70 by 90 feet, two stories high. The cost will be $16,000 and the structure will contain many modern improvements.

G. W. Worthing, formerly of the Worthing-Clark Automobile Co., at Fond du Lac, Wis., has established a new garage at 22 East Second street. He has been appointed district agent for the Overland.

The new Curtis Garage, erected for the Curtis Auto Co., Milwaukee agents for the Reo, Corbin and Hupmobile, is about ready for occupancy. It is located on Eighth street, just south of Grand avenue.

The Dominick Automobile Company, of Chicago, has been incorporated with a capital stock of $10,000. The company will engage in the automobile business and conduct a general repair and machine shop.

The Pittsburg Automobile Academy has established a general repair shop and garage at 5811 Penn avenue, East End, where it is now overhauling from six to a dozen cars a day for the benefit of its students.

Duluth will have a $50,000 garage in June. The building is almost completed. It is located back of the Board of Trade and is owned by E. J. Filiatrault. It will be two stories and of the most substantial concrete construction.

Manager Harry A. Bell, of the Metropolitan Motor Car Company, Spokane, reports the completion of his new garage. The building is of brick, two stories high, with an approximate floor space of 15,000 square feet. This firm handles the Premier, Pullman and Lozier cars.

Mathias R. Kondolf has lately secured the agency of the National car for Rochester, N. Y., and vicinity, and intends to occupy a large garage at Monroe avenue bridge, in the near future. This garage is 71 ft. front on Monroe avenue, and runs back 115 ft.; three stories high, of steel and concrete construction and fireproof.

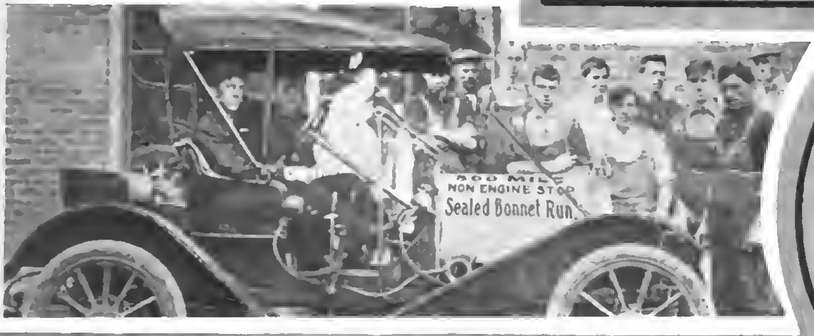
The Metropolitan Garage, which will be located in the quarters formerly occupied by the Roberts Motor Company, of Jacksonville, Fla., will handle the Gramm truck throughout Florida. The remodeled building will be ready for occupancy in the near future. W. F. Alley is in charge.

Standard Automobile Company, Cleveland agents for the Packard, and the Ohio sales branch of the Baker Motor Vehicle Company have just occupied the largest salesrooms and garages in Cleveland. The structure is located at Euclid avenue and East Seventy-first street. The building is of brick and stone construction and has a frontage of 160 feet on Euclid avenue and 200 on East Seventy-first street. The Baker department is capable of charging sixty cars at one time.

W. P. Crowley and A. H. Grindle, of San Francisco, are erecting a garage and will open for business July 1. The building will be a two-story brick, 82 ft. 6 in. by 137 ft. 6 in., costing $16,000, with basement the same size, for dead storage, lockers and machine shop. On the main floor there will be three large show windows for rent, and, with the exception of the office and store room, the rest of the floor will be devoted to live storage. The second story extends back only about one-third of the length of the building, and will be used exclusively as a lounging room for the chauffeurs.

The Buick Auto Supply and Garage Company has purchased a site on North Grand Boulevard, Detroit, and plans are being prepared for what will be one of the largest garages in the country. The property has a frontage of 245 feet and a depth of 150 feet, and the structure will cover the entire lot. The building will have an area of 36,750 feet, the front portion, 50 feet deep, being two stories in height. Back of this will come the garage proper, one story in height, 100 by 245 feet, and entirely free from posts. A complete machine and repair shop will be maintained, and it is the intention to have machines from all over the State sent here for overhauling and repairs. The Detroit garage will be the first of a string of forty it is proposed to establish throughout the State, and will be operated by the Michigan Buick Auto Supply & Garage Company. Despite the similarity of names, there is no connection between this concern and the Buick Motor Company, of Flint.

WITH THE AGENCIES



Hudson car which made 500 mile non-stop run in far away Hawaiian Islands, averaging nearly 19 miles per gallon

G. C. MacCullough, new appointee as manager of Penna. Rubber Co.'s N. Y. branch.

A. S. Lanich, of Baraboo, Wis., is a new agent for the Halladay in Western Wisconsin.

T. G. Coburn and E. B. Dennie, Newport News, Va., have become agents for the Studebaker, E-M-F and Flanders cars.

H. J. Smith, of Ravenna, O., has been appointed Regal agent by J. C. Hipp, manager of the Regal Motor Sales Company, Cleveland.

The Duquesne Motor Company has secured the Greater Pittsburgh agency for the Auburn car. It is also handling the Sebring car this year.

H. Heller, of Youngstown, O., has been chosen agent for the Clark and Empire cars by the Vail Motor Sales Company, of Cleveland.

Seamless Rubber Company, New Haven, Conn., opened a Boston salesroom at 685 Boylston street for the sale of the Bragg stitched tire and the Kantleak inner tubes.

The LeGrand Automobile Company, of Wilkesbarre, Pa., has taken on the agency of the Cole "30" for Luzerne, Columbia, Lackawanna and Carbon counties.

G. E. & H. J. Habich Company have taken the agency for the Cole "30" for New England and have opened a temporary salesroom at 185 Summer street, Boston.

Delaware Automobile Company, of Delaware, Ohio, of which Joseph Neville is general manager, has taken the agency for the Buick, and E-M-F lines for Delaware County.

Standard Tire Traction Company, manufacturers of Standard Chain Grips, opened salesrooms at 399 Boylston street, Boston. M. A. Kennedy is general manager.

The Columbus branch of the Studebaker company, of which A. J. Pray is manager, has been extended to include all of Southern Ohio, a part of West Virginia and Northern Kentucky.

The Gehl Bros. Manufacturing Company, of West Bend, Wis., has taken the agency for the International line. Each of the company's traveling men will be equipped with an International.

The Acme Auto Car Company, of Covington, Ky., has secured a floor space of 12,000 feet on one floor. The concern has the agency of the Badger and Clark cars. L. H. Sackett is manager.

The B. F. Goodrich Rubber Company opened new salesrooms in Cleveland last Saturday. A complete repair department and a full line of tires is on display. The new quarters are fitted up luxuriously.

F. C. Wiswell, of Elkhorn, Wis., is a new Studebaker agent in the south central Wisconsin territory. Mr. Wiswell will open a garage on May 15. Hugh Squires will have charge of the repair department.

J. Ernest Quimby has joined the Boston sales force of the E. R. Thomas Motor Company. Percy Musson has been appointed assistant superintendent of the service department of the same Thomas agency.

H. S. Moore, one of the oldest automobile dealers in Cleveland, has taken over the agency of the Overland line for Northern Ohio. He will have an allotment of 200 cars and will open a branch office on the west side of the city.

Commercial Auto Sales Company has been organized and located in salesrooms at 2158 East Ninth street, Cleveland. Chase delivery wagons and Gramm-Logan trucks will be distributed. J. A. Boyd has been chosen local manager.

H. H. MacDonald, C. T. Schaefer and J. E. Ellison, formerly in the St. Louis Car Company automobile department, are now connected with the Embree-McLean Carriage Company, of St. Louis, in making and selling the Embree-McLean "35."

Personal Trade Mention

Z. B. Leonard, of South Bend, Ind., will have charge of the Perfection Spring sales in the Middle West.

The Gasoline Motor Efficiency Company, of Jersey City, manufacturers of the Home, has secured the services of Jacob Hoffman as superintendent.

W. Owen Thomas will be identified henceforth with the Fal Motor Company as consulting engineer, according to an announcement made recently by that company.

A. R. Brown, formerly with the Interstate Sales Co., has returned to the Atlanta Ford branch, with which he was connected before he went over to the Interstate forces.

P. S. Steenstrup, former manager of the Hyatt Roller Bearing Company, has been appointed manager of the new branch of the Columbia Motor Car Company at Seattle.

Earl J. Moon, who was dangerously ill with diphtheria in Chicago, is convalescing at his home in Washington Terrace, St. Louis. He is still under the care of his physician.

George G. Dunham, president of the Royal Tourist Car Company, spent the week at the New York branch. Several new salesmen will be added to the sales force of the metropolis.

Roy Thomas, former centerfielder of the Philadelphia and Boston National League clubs, has signed with Manager W. F. Smith, of the Maxwell-Briscoe Company, of Philadelphia, in the capacity of salesman.

W. T. Helfer, formerly branch manager of the Diamond Rubber Company, Boston, Mass., and recently sales manager of the Springfield Metal Body Company, Springfield, Mass., has severed his connection with the latter concern to join the Racine Mfg. Co., of Racine, Wis., in which he has taken an interest.

REALM OF THE MAKERS

Party of 75 St. Louis automobilists lined up on the principal street of Stuttgart, Ark., upon occasion of a recent trip there

Richard Bacon, Jr., latest addition to sales force of Hudson Motor Co., Detroit

The Pullman Motor Car Company increased its capitalization April 30 from $100,000 to $500,000.

Oscar Lear Automobile Company, of Springfield, O., increased its authorized capital from $100,000 to $500,000. The increase was made to permit enlargements.

Columbus Buggy Company, manufacturer of the Columbus-Electric and the Firestone-Columbus, is now engaged in preparing models for the 1911 season.

The Nickel Manufacturing Company, of Pontiac, Ill., has placed on the market a five and a half pound automobile pump, standing ten inches high. The pump is operated by the engine.

Stewart & Clark Mfg. Co. is enlarging its factory plant at Chicago with an addition 110 by 125 feet. The building will be two stories and basement and is expected to be completed by July 4. The concern makes speedometers.

Factory Auto Supply Company was capitalized with a capital stock of $10,000. The company will be located in Chicago, and will deal in automobiles, motorcycles, accessories and supplies. The incorporators are George W. Stephens, William A. Conover and Spencer Wood.

The Universal Tire Protector Company, Angola, Ind., has been reorganized with a capital stock of $30,000 fully paid, the officers being S. C. Wolfe, president; E. S. Croxton, vice-president; J. R. Nyce, secretary and W. W. Love, treasurer. Mr. Croxton is vice-president of the First National Bank of Angola.

After two years absence from the track, Montague Roberts, it is announced will drive the Houpt-Rockwell entry during the 24-hour race which will be held at Brighton Beach, May 13-14. Mr. Roberts has had much to do with the designing of the car he will drive. Stanley Martin will be with Mr. Roberts.

The Brown Auto Carriage Company, of Cleveland, builders of automobile bodies, moved to a new factory May 1. The new plant has a floor area of 40,000 square feet, and gives this company one of the largest body factories in the country. Tops, windshields and upholstery work are side lines of this concern.

The Temperin Company was incorporated in Illinois by Secretary of State James A. Rose, with a capital of $5,000. The company will locate offices in Springfield, Ill., and will manufacture Temperin, a product for tempering and saving the temper of steel tools. The product was invented by Justis Moore.

The Overland Automobile Company states that it purchased material for 20,000 cars for 1910, that the material is in hand, and that the production will be nearer to 25,000 than to 15,000 which was scheduled on page 683 of THE AUTOMOBILE, April 7 issue. Overland shipments for March were 2,300 cars; April will reach 3,000.

The Detroit Carbureter Company has been organized with Byron Robbins as president, E. M. Broderick, vice-president and general manager, Dr. H. S. Kiskadden, secretary and Newton Annis, treasurer. Within a month the new company, which has established offices at 239 Jefferson avenue, Detroit, will be turning out 200 carbureters.

The New Departure Manufacturing Company, of Bristol, Conn., is making additions to the big plant, which will afford an increase in floor space of 32,000 square feet. The foundations have also been laid for additional gas-engine equipment. Gas engines have been used by the company for power purposes for some time with good results.

W. T. Ensign, of La Crosse, Wis., has perfected a pistonless gas engine for use in motor cars, boats, cycles and stationary work. The engine is said to utilize the power created by the combustion of two gases, is a great fuel saver and may be geared to tremendous speed. Two La Crosse engine builders are negotiating for the purchase of the rights to manufacture the motor.

Barndt and Johnston Auto Supply Company which has been located on Donaldson street since its organization in 1905, has been moved to South Columbus, where it will occupy the plant formerly used by the Columbus Woodworking Company. In all 45,000 square feet is contained in the new plant. The company makes bodies and accessories.

Charles T. Jeffery has assumed complete control of the manufacture and sale of the Rambler, manufactured by Thomas B. Jeffery & Co., at Kenosha, Wis., according to official announcement. Mr. Jeffery was for sixteen years a partner with his father in the big concern, and is widely known in the trade. The business of the company will continue without change in policy.

The Canton Buggy Company, Canton, Ohio, is making a new delivery wagon, and it is expected that this company will go into the production of its type of delivery wagon on a consderable scale. The idea is to take advantage of the present state of the art, produce a wagon of the greatest possible utility from the point of view of radius of action, low cost per ton mile of the goods transported, with a particular eye to the future. considering depreciation.

An addition to the Moon Motor Car Company factory is now being built for the accommodation of the increased number of cars in the testing stage. The test cars, while undergoing their road test preparatory to the 100-mile perfect score run, which each must take before it is sent to the paint shop, will be housed in the new department, to be known as the test-car garage. The garage will be large enough to accommodate thirty to forty cars. It is being built in the quadrangle formed by the three wings of the big plant and a high fence topped with barbed wire. The new department will be ready for occupancy in April.

NEWS IN GENERAL

Louis Strang in the Pierce-Racine car which he drove in the New Jersey reliability contest from New York to Atlantic City and return.

E. R. Hollander, vice-president Fiat Automobile Company, New York City

Fisk Rubber Company has been installed in one of the most handsomely arranged houses in St. Louis at 3917 Olive street.

The Monarch Auto Top and Supply Company, with offices in Chicago, has certified to an increase of capital stock from $2,500 to $20,000.

The Benoist-Buel Company has succeeded to the management of the Benoist Bros. Manufacturing Company, of St. Louis, and in a short time will move to 3923 Olive street.

R. A. Palmer has been elected president of the newly formed Commercial Club of Pontiac, Mich. Mr. Palmer is secretary and general manager of the Cartercar company.

Over 560 automobile horns made by the Gabriel Horn Mfg. Co., of Cleveland, were lost in the wreck of the steamship "Minnetonka" off the British coast. The horns were part of the jettisoned cargo.

The Thirty-eighth annual convention of the Carriage Builders' National Association will be held in Cincinnati, O., during the week commencing September 25, 1910. The exhibition will be from September 26 to 30, inclusive. The convention will be September 27, 28 and 29.

The United States Light & Heating Company, general offices at 30 Church street, New York, announce the removal of the Chicago office, May 1, from 745 Monadnock Building, to 1013 People's Gas Building, Michigan avenue and Adams street.

D. Rees Davis has taken over the Houseman-Blake Automobile Company, and in future the firm will be known as the Davis-Blake Automobile Company. The new company will handle the Springfield car and its offices will be at 5037 Delmar boulevard.

The Emergency Repair & Call Company has begun business at 2801 Clark avenue, Cleveland, with C. H. Votteler as manager. The company will remain open day and night and will make a specialty of calling for and repairing cars in any part of the county. A motor wreck train equipped with mechanics is subject to calls days and night.

E. D. Layman, manager of the Chicago Road and Realty Company, which is projecting "The Great White Way" between Chicago and Milwaukee, says that the company has begun to acquire title to lands on the proposed route. The highway will be 76 miles long, with a 66-foot highway for motor traffic and two 20-foot public roads flanking it. The center division for street railway traffic will be eliminated.

The Clark Motor Company, capitalized at $50,000, to manufacture and deal in motor cars and to carry passengers, has been incorporated in Buffalo. The directors are Stanley B. De Long, John W. Van Allen and Henry J. Rente. Incorporation papers were also filed in Buffalo by the Regal Auto Company, with a capital of $10,000, with Clarence E. Hancock, Wilfred W. Porter, Jr., Myron S. Melvin, Robert G. Boyd and Harry D. Van Brunt, all of Syracuse, as the directors.

Pittsburgh automobile firms are studying the matter of outdoor motor carnivals. They believe that more real good can be accomplished in a sales way through these outdoor carnivals than through the winter indoor meetings. It has been found that in general prospective buyers take much more interest in seeing the cars in motion than they do in a long continued study of them under electric lights, and arrangements are being made by leading companies in this city to put on one or more big summer carnivals this year.

George C. John, New York agent for the E-M-F and Flanders, has sold out to the Studebaker Company, the purchase being in pursuance of the latter company's policy of handling these cars, the manufacture of which it now controls, from its own branch offices. The deal was made last week at a meeting at the Hotel Belmont in New York, between Mr. John and Walter E. Flanders and Clement Studebaker, representing the Studebaker Company. It is said the price received by Mr. John will practically cover his season's profits, and that as an evidence of good will he will this summer drive a handsome Studebaker-Garford car.

Gibney & Bro. Invade New York

The announcement is made that the well-known Philadelphia house of James L. Gibney & Brother is going to invade New York with a tire and accessory store at 248-52 W. Fifty-fourth street.

James L. and John L. Gibney opened a bicycle-tire repairing establishment in a back room at 1015 Arch street, Philadelphia. They soon outgrew their quarters and in the following year tripled their space and started the sale of bicycle tires and later in the year removed to still larger quarters at 916 Arch street where they took on agencies for pneumatic automobile and solid carriage tires. In 1902, they moved to 828 Arch street. Shortly after establishing themselves in this place they extended their scope by beginning the sale of solid motor tires.

In 1905 a location was secured at 211-13 N. Broad street, and accessories were added to the line.

In April of 1909 they erected a three-story building at 215-217 N. Broad street, where they carry one of the very largest stocks of auto tires and accessories in the country and also have exceptional facilities for repair work.

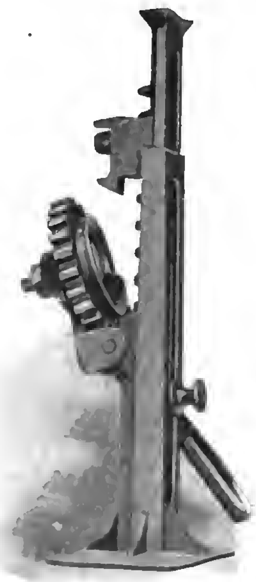
The Gibney firm developed the sale of the Fisk, Continental and Firestone tires in the Philadelphia field.

The establishing of the New York store, which will occupy the ground floor and basement of a large new building just off Broadway is the latest development in the upbuilding of this great business from an insignificant start.

Prominent Automobile Accessories

NEW JACK WITH QUICK ADJUSTMENT

The Ashland Manufacturing Company, Ashland, O., offers a new jack of which much interest is being taken by autoists. The illustration here given of this jack shows how simple it is, and it is claimed by the maker that the adjustment feature is of particular value, it being the case that the action is not only quick but positive. The Crown jack, as it is called, is made in the usual sizes, the materials employed are the best for the purpose. For a double-acting jack, considering the high character of the material and workmanship, the price is well within bounds, and



Ashland Jack Demounted

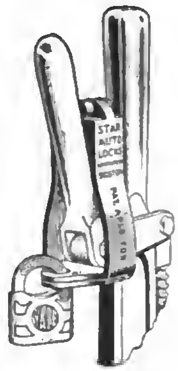
the rate at which these jacks are being made and shipped speaks well for the enterprise of the firm making them. The cut elsewhere on this page shows the jack partly dissembled, this act of taking it apart showing better than could any other the actual construction. As is to be seen from the cut, there is a large toothed wheel on the end of the operating lever. This gear and lever are finished and inspected with unusual care, in order to make the jack one that can always be depended upon.

THREE IN ONE OIL FOR MAGNETOS

The well-known lubricating oil, which is sold everywhere under the brand name "Three in One," has recently attracted the notice of the automobile fraternity as a lubricant to be used in magnetos, and the Three in One Oil Company, 42 Broadway, New York City, claims for this oil that it will serve extremely well for this important purpose, its advantages being set forth as (a) it may be obtained even in the remotest districts in country general stores, as well as in the large distributing centers; (b) it has exactly the right consistency for use in delicate bearings, and will prove efficacious in magneto work on this account; (c) the oil will not gum up, is free from deleterious admixtures, and has the especial virtue of coming in sealed packages, which serves as a guarantee.

EMERGENCY LOCKING DEVICE

Automobiles continue to be stolen and there are still many accidents which occur solely through someone, humorously inclined or otherwise, changing the positions of the operating levers so that a gear is engaged when the driver thinks that the lever is in the neutral position. This will now all be changed by the use of a new emergency lock, known as the Star Auto Lock, which has just been put on the market by the Star Auto Locks Company, 53 State street, Boston. The device is the acme of simplicity, consisting of a simple metal loop which may be placed over the operating handle in such a way as to prevent the working of the latch. In this way the lever may not be moved. The metal loop, as the cut shows, is locked in place with a padlock, the owner of the car carrying the key. The construction is so simple and the work of putting it on and taking it off so easily done that no time is added to the usual time of starting or stopping.

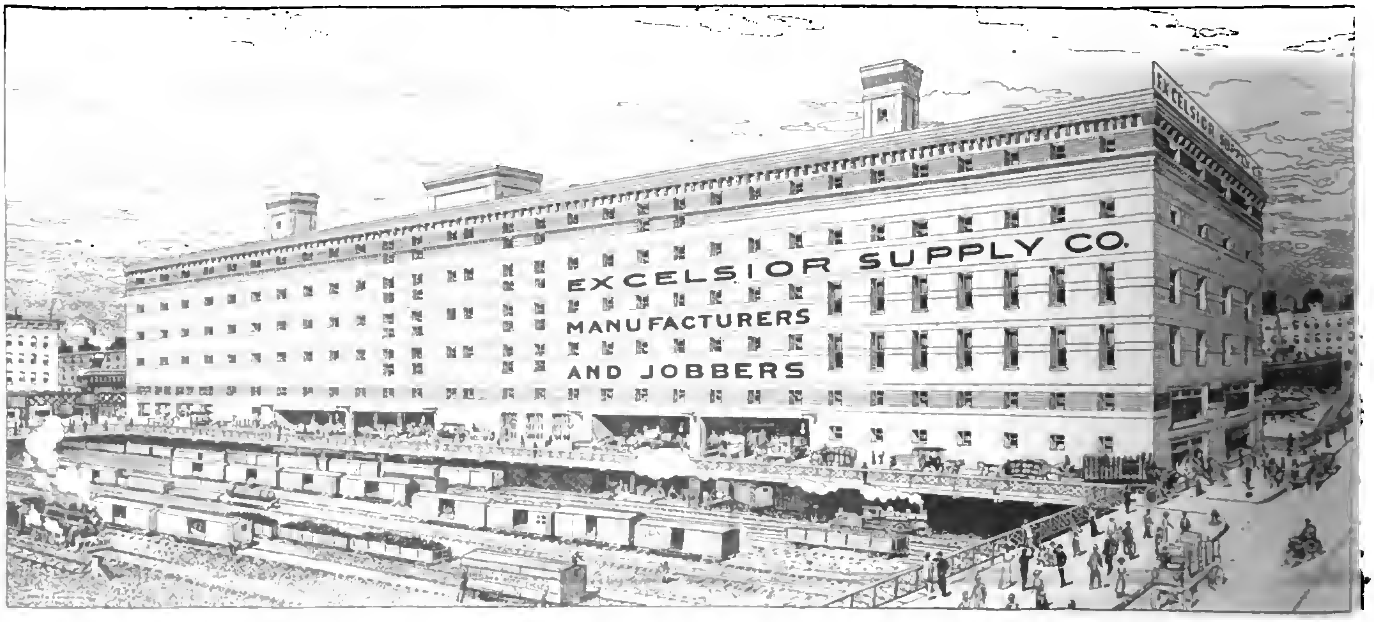


Star Auto Lock

RONSON AUTO INITIALS

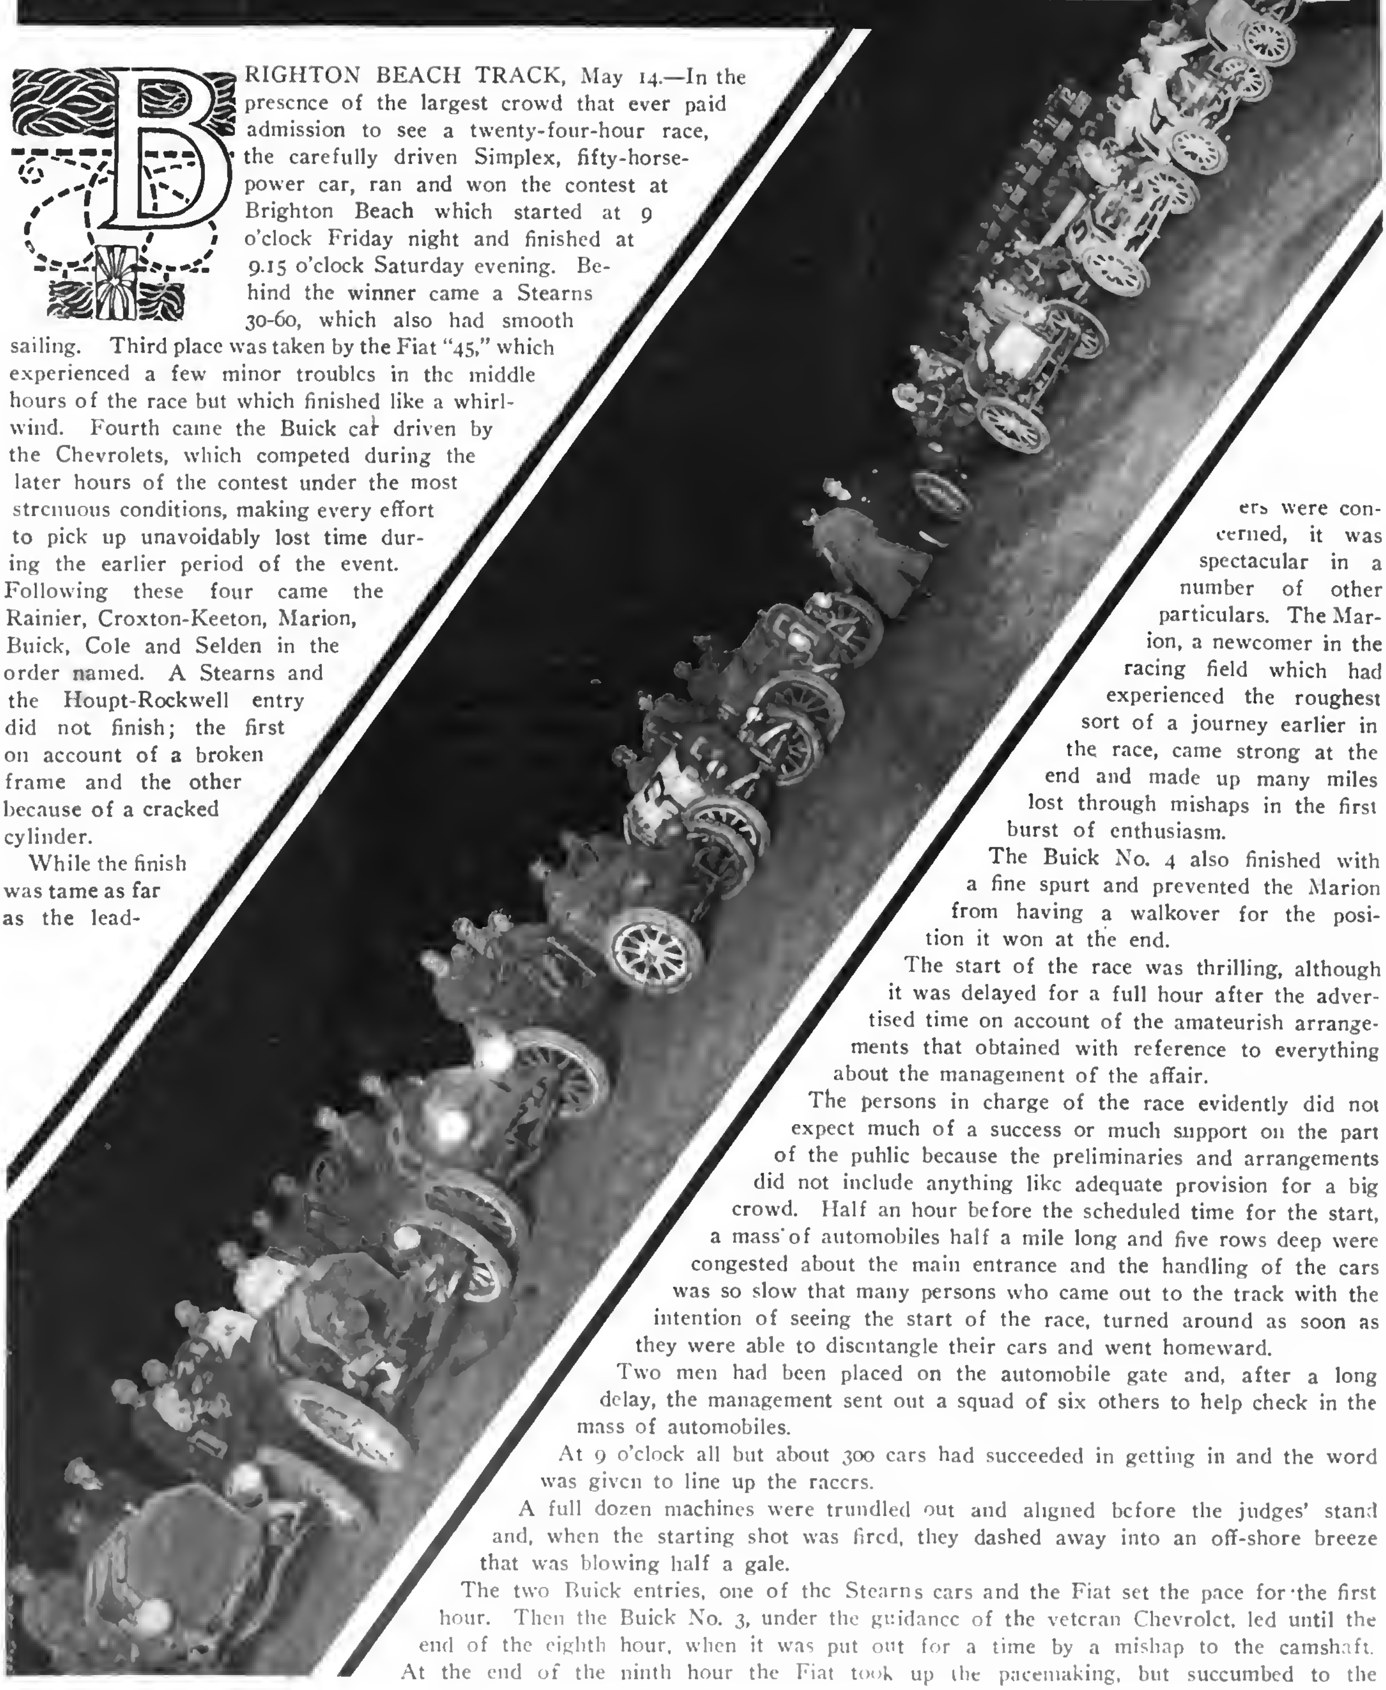
Everyone has a certain pride in letting it be known that he or she, as the case may be, possesses an automobile. This pride of ownership which works out in the mass of names found in all public places, in an automobile takes the form of an ornamental letter or monogram of highly polished brass, which may be placed on the radiator front or elsewhere. The monogram shown is a specimen of the work done in this line by the Ronson Specialty Company, 7-15 Mulberry Street, Newark, N. J.

Ronson Monogram



Immense New Home of Excelsior Supply Company at Chicago, Where Everything in the Accessory Line Is Carried

THE AUTOMOBILE



BRIGHTON BEACH TRACK, May 14.—In the presence of the largest crowd that ever paid admission to see a twenty-four-hour race, the carefully driven Simplex, fifty-horsepower car, ran and won the contest at Brighton Beach which started at 9 o'clock Friday night and finished at 9.15 o'clock Saturday evening. Behind the winner came a Stearns 30-60, which also had smooth sailing. Third place was taken by the Fiat "45," which experienced a few minor troubles in the middle hours of the race but which finished like a whirlwind. Fourth came the Buick car driven by the Chevrolets, which competed during the later hours of the contest under the most strenuous conditions, making every effort to pick up unavoidably lost time during the earlier period of the event. Following these four came the Rainier, Croxton-Keeton, Marion, Buick, Cole and Selden in the order named. A Stearns and the Houpt-Rockwell entry did not finish; the first on account of a broken frame and the other because of a cracked cylinder.

While the finish was tame as far as the leaders were concerned, it was spectacular in a number of other particulars. The Marion, a newcomer in the racing field which had experienced the roughest sort of a journey earlier in the race, came strong at the end and made up many miles lost through mishaps in the first burst of enthusiasm.

The Buick No. 4 also finished with a fine spurt and prevented the Marion from having a walkover for the position it won at the end.

The start of the race was thrilling, although it was delayed for a full hour after the advertised time on account of the amateurish arrangements that obtained with reference to everything about the management of the affair.

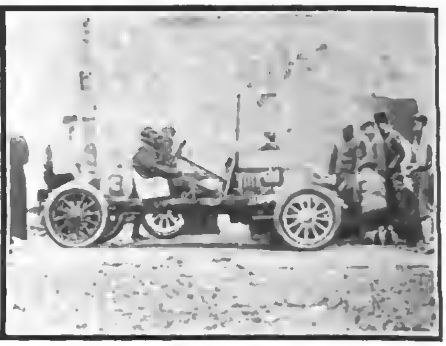
The persons in charge of the race evidently did not expect much of a success or much support on the part of the public because the preliminaries and arrangements did not include anything like adequate provision for a big crowd. Half an hour before the scheduled time for the start, a mass of automobiles half a mile long and five rows deep were congested about the main entrance and the handling of the cars was so slow that many persons who came out to the track with the intention of seeing the start of the race, turned around as soon as they were able to disentangle their cars and went homeward.

Two men had been placed on the automobile gate and, after a long delay, the management sent out a squad of six others to help check in the mass of automobiles.

At 9 o'clock all but about 300 cars had succeeded in getting in and the word was given to line up the racers.

A full dozen machines were trundled out and aligned before the judges' stand and, when the starting shot was fired, they dashed away into an off-shore breeze that was blowing half a gale.

The two Buick entries, one of the Stearns cars and the Fiat set the pace for the first hour. Then the Buick No. 3, under the guidance of the veteran Chevrolet, led until the end of the eighth hour, when it was put out for a time by a mishap to the camshaft. At the end of the ninth hour the Fiat took up the pacemaking, but succumbed to the



Mulford in Stearns Speeding at Brighton   DePalma Making Fast Time in Fiat Car   Arthur Chevrolet in Buick Three, Buick Camp

Ranier at the end of the tenth. By the twelfth hour the steady pace of the Simplex began to tell, and a little extra speed on the part of Basle and Poole put their machine out in front. From the twelfth hour to the finish the Simplex went on about its business and widened the gap between it and its competitors. The winner only made one sharp spurt during the race. All the rest of the time it was driven with just a shade in reserve. It laid off the furious pace of the start and was ready when the time came to shoot past the tiring field. The Stearns car that finished second also avoided the terrific speed of the early pace, and while prominent throughout the struggle did not show its real running until after the fifteenth hour, when it passed the Fiat and settled in behind the Simplex for the run home. The Fiat showed sparkling speed in half a dozen wild bursts and was always a dangerous contender.

Winning Simplex, Poole Driving, As It Appeared After the Strenuous Race

Chevrolet's Buick which set the early pace made a gallant showing despite the loss of nearly two hours early Saturday. At the end it was going along smartly and holding its own. The Rainier plugged along steadily from start to finish, occasionally making high figures and once assuming the lead, but never having quite the necessary ground to loom up as the winner. The showing of the Croxton-Keeton machine was creditable and its progress throughout the race was steady. The Marion, which went through the fence early in the race, made an astonishing finish, running tremendously in the last stages of the contest. This applies also to the Burman Buick.

The Cole and Selden entries were given easy drives and both showed good speed and staying qualities.

Weather conditions were varied during the running of the race. The start was made in the cold, snappy wind, which quieted down as the night grew older. During Saturday afternoon heavy rain fell, soaking the track and the racers but really doing a service in that it smoothed out some of the ruts and furrows that had been torn into the turns by the whirling cars and really made the going a trifle safer.

If the rain had not fallen, some sort of repair work would have been necessary on the clubhouse turn and also on the far stable turn. As it was, the effect of the drenching was to make the course slower for a while. There was only one delay during the race. Shortly before 1 o'clock Saturday morning the red and green signals were displayed at the judges' stand and for fifteen minutes the cars were halted. The incident proved to be a false alarm and the cars were soon sent away again upon their long journey.

The conditions of the race were as follows: It was run under sanction of the A. A. A. Contest Board and in accordance with its rules. The classification was under Class D, which reads: "Open to any gasoline car which complies with the definition of a motor

Disbrow in a Rainier, a Prominent Contender. Croxton-Keeton, a Newcomer, Gained Fifth. Strang in a Marion on One of Lower Turns car, without restriction as to piston displacement, weight, price or quantity produced."

The start was standing.

A. B. Cordner, chairman of the Brighton Beach committee of the Motor Racing Association, in defining the status of the entries, stated that "There may be stock cars in the race. They are not barred. Neither is any other kind of a gasoline automobile. Any old kind of a teapot had a right to go."

When permission was requested to view the contesting cars from the vantage ground of the paddock, Mr. Cordner emphatically denied it.

"What's the use," he remarked.

But without reference to the value of the race from the viewpoint of the maker and the public, it was a gallant spectacle. Despite inadequate preparations for such a crowd, the sporting picture afforded by the racing machines was inspiring. The successive spurts of the contestants always brought the crowd to its feet and the fine points of driving were liberally appreciated and applauded. Full 30,000 persons paid admission during the 24 hours. Possibly there were 5,000 more.

Behind the stands, in the runways and parked along the streets surrounding the track the greatest aggregation of automobiles ever gathered together, in this country at least, brought the major portion of the crowd. It is variously estimated that there were between 3,000 and 4,000 that succeeded in gaining entrance to the enclosure while the race was being run, and Friday night there were hundreds that did not succeed in getting in. The public got its money's worth of spectacular track racing enjoyment.

The racers failed to break the record through the shower Saturday afternoon, although the pace was not of the record-breaking variety even before that time. However, it is likely that one or two cars, possibly three, might have pressed the mark closely if the rain had not intervened.

Circular Track Collects Its Customary Toll

The weather was inclement; it was much too cold for drivers to remain long in good fettle and the wind blew at a terrific pace, all of which, together with the fact that it was night time and that the track had furrows cut in it to quite some depth after the first hour or so, led up to a rather bad accident to the Marion car which crashed through the fence. It was 18 minutes after 11 on the upturn of the track. William F. Bradley, the mechanician on the car, was the victim whom the grim specter came after. He was taken to the Coney Island Reception Hospital at about 12 o'clock, but his injuries were too severe to be coped with by capable medical attention and his death was ultimately announced. The driver, Gilbert Anderson, was thrown out of his seat and escaped, it is said, without any hurt. The mechanician, Bradley, was 29 years of age, was married, and lived at No. 11 Halsey street, Newark, N. J. He presented much promise in the racing field, and among his most recent achievements was that of driving a Marion car to a perfect score in the Around New Jersey Reliability Run during last Tuesday and Wednesday.

Following is the score of contestants and drivers by hours:

Score by Hours During the Whole Day

Paulhan to Try Long Flight

Cable dispatches report that Louis Paulhan, encouraged by the success of his remarkable aerial journey from London to Manchester, will soon try to win the special Michelin prize of $20,000, for the first flight from Paris to Clermont-Ferrand, a distance of 217 miles "as the crow flies" and 268 miles by road.

The rules for the Michelin prize are very simple. The aviator attempting the journey from Paris to Clermont may start anywhere in the departments of the Seine or Seine et Oise. He must first turn a complete circle around the Arc de Triomphe in Paris, and on arriving at his destination he must circle the spires of the Cathedral at Clermont-Ferrand, landing on the summit of the Puy-de-Dome, 4,800 feet high. Two must make the trip, and the time limit is six hours.

Galveston Races in August

Preparations are being made for the automobile races to take place on Galveston Beach, August 3, 4 and 5. Capt. J. W. Munn, who has the arrangements in charge, has announced that more than $3,000 will be awarded as prizes for the winners of the various events.

Entry blanks for the race meeting which will be held on the Galveston, Tex., beach August 3, 4 and 5 have been distributed. The program provides for ten events and cash prizes amounting to $2,225 will be distributed. The ten-mile events will be run over a five-mile circuit and the twenty-mile races will be decided over a ten-mile course. No admission fee will be charged this year and a big attendance is looked for by the management.

Queen City to Have Auto Speedway

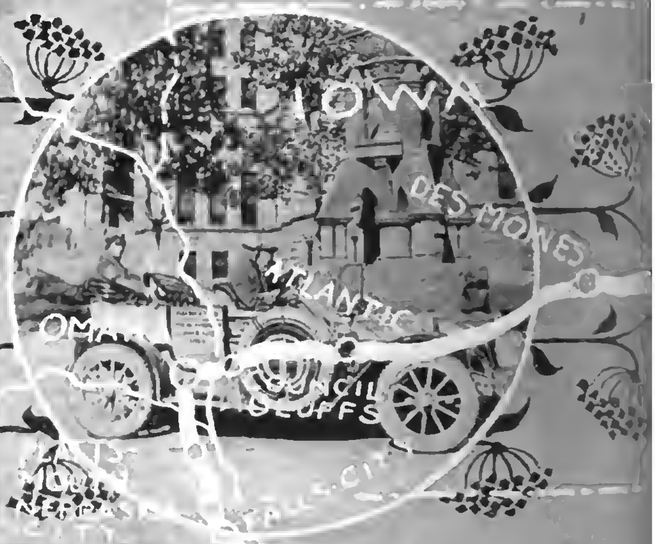
CINCINNATI, May 16—J. T. Earle, president of the National Bank of Latonia, H. H. Meyers, president of the Latonia Jockey Club, and an executive official of the Chesapeake and Ohio Railroad are behind a plan to give Cincinnati a speedway similar to the ones in operation at Indianapolis and Atlanta. Options on a tract of land lying between the Licking River and the Louisville and Nashville Railroad right of way in Covington have been taken, and the purchase of it seems quite probable within a short time.

Two Runs for St. Louis Motorists

ST. LOUIS, May 16—Motorists of St. Louis are enthusiastically preparing for the two reliability runs to be held in June. Both the automobile club, which is to give a one-day contest the first week in June, and the Manufacturers and Dealers' Association, which will give a three-day contest the last week in June, have had scouting parties out for a week in an effort to determine the best route. Neither has announced the exact date of the contest it is to give.

Indianapolis Gets Cobe Race July 4

CHICAGO, May 17—The deal between the Chicago Automobile Club and the Indianapolis Motor Speedway, relative to the running of the Cobe Trophy race on the Hoosier Motordrome, was completed to-day when E. A. Moross, manager of the Indianapolis track and the Contest Board of the Chicago Automobile Club, settled the details.



Glidden Pathfinder Com

VIRGIN territory has been mapped out for the Glidden tour for this year; thirteen states are included in the orbit; much of the way is yet to be traversed by automobiles in numbers, but the surprise of the last two years came from the very country traversed. It was not so long ago that automobile makers labored under the impression that automobiles would not find a market in the remote districts for years to come, and it came as a surprise to them when the Western farmers fell into line and became heavy purchasers of the better makes of automobiles.

The path of the Glidden Tour follows the original itinerary, beginning at Cincinnati, O., thence through Kentucky, Tennessee, Alabama, Mississippi, Arkansas, Texas, Oklahoma, Kansas, Missouri, Nebraska, Iowa and Illinois, terminating at Chicago

The Utility Side of the Glidden Tour

While there is a sportive phase involved in the tour, the fact remains that the industry as a whole is to be benefitted, and in the important ways as follows:

(A) Road building will be given an impetus; this is probably the most important angle.

(B) Manufacturing, not only of automoblies, but accessories as well, will be extended; the Southwest is not now without its automobile industries.

(C) The good news of the splendid ability of automobiles will be spread to the remotest hamlet in the outlying counties; farmers will find further reason for taking an interest in the problem of the emancipation of the horse, and artisans will learn how to part the shackles of industrial life; they may be privileged to work as usual, but they will also learn how to enjoy life in companionship with the automobile.

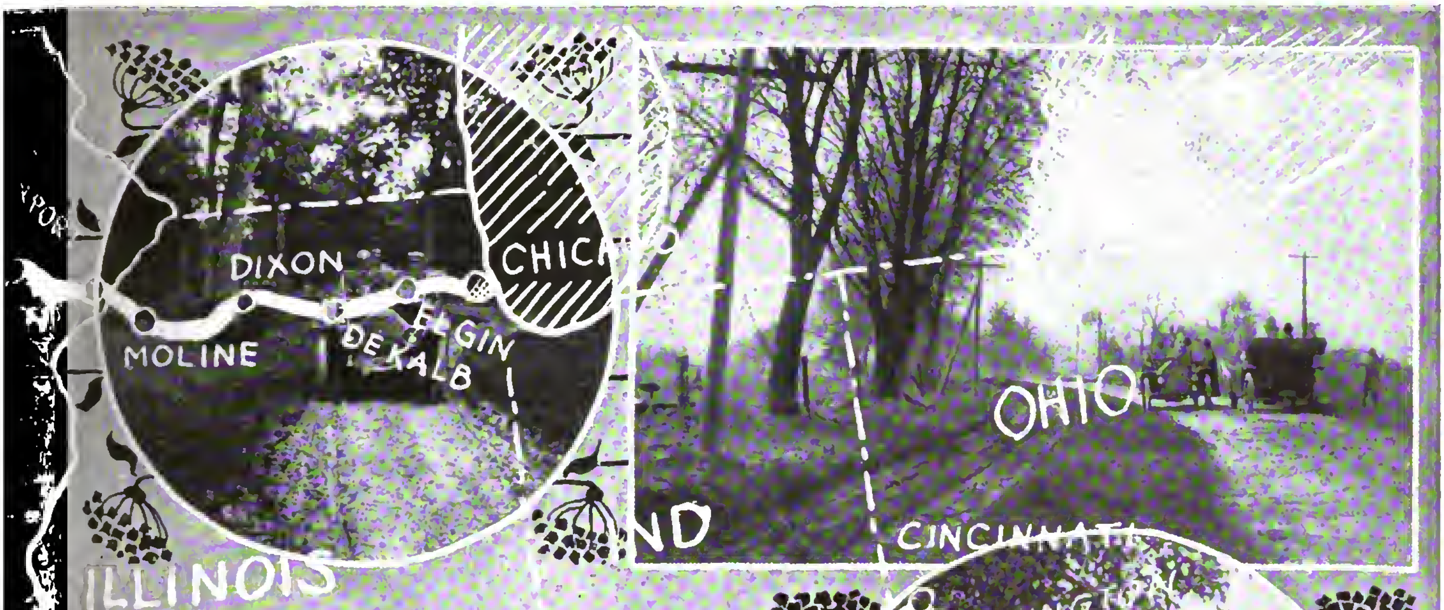
Present State of Industry in the Southwest

The State of Ohio is now the largest producer of automobiles of all the states through which the tour will be made; Illinois comes next, and the remaining states mentioned are more or less in embryo, but they are accomplishing more than a little, as the following tabulation will show:

Production of Automobiles By States

STATE	AUTOMOBILES	VALUATION
Ohio	40,000	$80,000,000.00
Illinois	10,000	15,000,000.00
Iowa	5,000	10,000,000.00
Missouri	4,000	9,000,000.00
Kentucky	500	600,000.00
Tennessee	300	400,000.00
Kansas	300	400,000.00
Nebraska	250	300,000.00
Texas	100	100,000.00

The total production of automobiles in the states through which the Glidden Tour will pass is in excess of 60,000, as estimated for 1910, the total value being $134,000,000.00, giving employment to 60,000 men, expending for labor more than $50,000,000.00 in the manufacture, which figure allows nothing for the indirect expenditures, as in garages, repair shops, and in divers other ways. That these secondary methods of employment are beyond the dream of the man who contents himself with merely existing will be indicated



pletes Its Strenuous Task

the mere statement that the upkeep of the automobiles made in these states worth $25,000,000.00 to the men who do the work, counting the money which ust be devoted to this service.

The cost of upkeep of the automobiles made in these states is figured on a asis of 20 per cent. of the selling price, and considering this basis it is fair to int out that good roads are needed. It is hoped that the citizens of these ates will reach the same conelusoin as that which actuates the road comissioners of such states as Massachusetts, New Jersey, and divers other astern states; it has heen learned that the cost of upkeep of automobiles and roads falls upon the citizens at large.

Good Roads Will Help To Solve Problems

If the Glidden Tour is in the nature of a missionary undertaking, it is t too much to say that the propaganda for good roads is one of the prime, if t the paramount, considerations. The progressive idea everywhere in Ameri- is based upon better means of transportation; improvement is the high aim, d the time has come when scientific road building must support mechanical ans of hauling merchandise.

It is estimated that $90,000,000.00 represents the present annual expend- re for road improvement, of which considerable sum fully one-half is utterly sted. It has been said that much of the money expended on road-building s to no purpose, the rain and the frost undoing the work as fast as it is comted. The great question is to build roads, but it is of equal importance to ld them well. Just now the Federal Government is taking an interest in work; just at the present time the Federal Government is indicating its ous intentions through Bill No. 6931, which has been favorably reported the Senate Committee on Agriculture, which provides for an appropriation $500,000 for the extension of the work of the U. S. Office of Public Roads aiding in the improvement of the public highways.

Highway Departments To Care For Roads

The several states are awakening to the seriousness of this great situation, evidence of which is sufficiently indicated by the proposed act creating a State Highway Department, and establishing a State Highway Commission, and the office of State Highway Engineer, all with a view to the construction, maintenance and repair of public highways and bridges in the State of Michigan. To fully appreciate the part which the Federal Government is taking in these matters, knowledge of the activity of Logan Waller Page, Director of Public Roads, U. S. Department of Agriculture, will have to be taken into account. The activities in Michigan at the present time reflect the skill and knowledge of Director Page, who drafted the Michigan Act on behalf of the Michigan State Grange. Many states are falling into line, the National Grange is doing masterly work, and it is the idea everywhere to study the whole situation from a scientific point of view and respond to the demands of the farmers.

It is the confidential hope of the projectors of the Glidden Tour, that citizens throughout the Southwest, to whatever extent they fail to appreciate the true situation, will reach a better understanding of the importance he automobile and good roads. Instead of wasting nearly $50,000,000 per num in the maintenance of roads which are but roughly improved, and ind of wearing out good automobiles on just such highways, the light, as it es from the experiences gained, reflects the more stable condition—it is light of experience.

Last Word About Harrisburg Endurance Run

HARRISBURG, Pa., May 12—The final results of the 3-day reliability tour conducted by the Harrisburg Motor Club were announced by Referee W. R. Douglas at 5 o'clock this afternoon, practically the entire day having been consumed in giving the cars a strenuous brake test and a thorough technical inspection to discover all breakages.

In the class A for touring cars, $2,000 and over, a Pullman was the winner with a perfect score. In class B touring cars, under $2,000, the Inter-State was victor with 11 points penalty, 8 points received on road work the last day and 3 points in the final examination, made up of 1 for bent fender iron, and 2 for a loose motor bearing, which bearing was not in adjustment when the tour started. In the runabout division, class C, over $1,600, a Kline Kar was winner with a perfect road score and perfect technical examination. In the runabout division, class B, under $1,600, a little two-cylinder Maxwell carried off honors from larger cars, winning as it did with a perfect road score and passing a perfect technical examination.

The report of the first two days of the tour as far as road performances are concerned appeared in last week's issue of THE AUTOMOBILE. The third day's run from Wildwood, N. J., to Harrisburg, by way of Philadelphia, a distance of 197 miles, proved the hardest of the tour. A heavy rainstorm drenched the tourists as far as Philadelphia, and from Philadelphia to Harrisburg a previous rain had put the roads in bad shape.

The Franklin No. 13, driven by John Burns, was the only car to have a perfect road score and outdoor tests but to suffer on the technical examination, receiving as it did 3 points, 2 for a broken muffler support, and 1 for a loose cover on a universal. No. 9 Kline Kar made a particularly good performance, being clean in every respect except for 5 points brake penalty. Of the nineteen cars which took the final examination eight passed it without revealing any derangement that brought a penalty upon them, these eight being the Pullman, Kline Kar in class A, the Enger in class B, two Kline Kars and a Pullman in class C, and the Maxwell and a Kline Kar in class D.

Kansas City Automobile Club Annual Hill Climb

KANSAS CITY, Mo., May 14—Watched by 3,000 spectators who had driven 10 miles to reach the firing line, the annual hill-climb of the Automobile Club of Kansas City, which was held on Dodson Hill this afternoon was a most interesting affair which resulted in a new record for the climb, made by A. O. Brooke driving a Lexington 40. Brooke, agent for the car here, held the previous record of 59 3-5 made in a Stoddard-Dayton in 1908, but he eliminated this entirely to-day when he climbed in 55 2-5 for the .6 mile. Summaries:

Event 1—Cars costing under $800. Krit, time 1:31 1-5.

Event 2—Cars costing between $801 and $1,200. Ford, time 1:06 1-5; Ford, 1:27.

Event 3—Cars costing between $1,201 and $1,600. Parry, time 1:06 2-5; Great Western, 1:07 2-5; Everitt, 1:18 3-5.

Event 4—Cars costing between $1,601 and $2,000. Jackson, time :58 4-5; Henry, 1:10; Auburn, 1:12; Enger, 1:15; Herreshoff, 1:27 1-5.

Event 5—Cars costing between $2,001 and $3,000. Pennsylvania, time 1:03; Jackson, 1:06 4-5; Great Smith, 1:10 2-5.

Event 6—Cars costing between $3,001 and $4,000. Palmer-Singer, time 1:05; Palmer-Singer, 1:06 1-5; Palmer-Singer, 1:26.

Events 7 and 8—No entries.

Event 9—Free-for-all, cars under $3,000. Jackson, time :55 4-5. Lexington, :56; Great Western, 1:00; Apperson, 1:00 4-5; Ford, 1:00 4-5; Great Smith, 1:02; Jackson, 1:05.

Event 10—Free-for-all. Lexington, time :55 2-5; Jackson, :56 1-5; Apperson, :59 1-5; Great Smith, 1:00 4-5.

Improving the Roads at Perth Amboy, N. J. Roller at Work

Steam Tractor Pulling Scraper, Road Improvement at Roanoke, Va.

New York Atlanta Pathfinder Enthusiastically Received

AFTER a trip that consisted of a series of ovations and receptions, the pathfinder car of the New York *Herald*-Atlanta ***Journal*** National Highway, Good Roads tour reached its destination in Atlanta, Monday. The Columbia 45-horsepower car made the trip without major mishap of any sort.

The car traversed every known variety of roads and a few that had been practically unknown up to the time of their discovery by the explorers. But in the main the going was good and in fully half of the course selected for the tourists next month, the roads were almost good enough to race over. Here and there a bad spot was found and then a little further along, the way would be worse, but from one end of the line to the other, there was only one space of any great importance upon which road-builders and road-repairers were not busy.

This spot is near Gettysburg, Pa., where the attitude seems to be that "we get all the tourist travel anyhow; what's the use of spending money on the roads?"

Across New Jersey and almost as far as Gettysburg, the roads were in their usually excellent shape and after passing the scene of the fiercest battle of the Civil War, with all its historic interest, the highways toward the South improve with abruptness. Through the foot-hills of the Blue Mountains and down the valley of the Shenandoah the going was enjoyable, although it will be better when the tour proper passes that way. The Maryland roads were in fair conditon and the course from Hallstown to Charlestown was being given a very thorough scraping and filling in preparation for the tour.

From there to the Virginia line, road building machinery was to be seen all along the way. In Virginia road-rollers and gangs of men were engaged in road work at several places and already the route to be followed by the tourists is comparatively free from "thank you ma'ams." From Harrisonburg to Staunton, the road is in racing condition. When the pathfinder approached the mountains near the Natural Bridge some dangerous bits of road were encountered on account of rains that fell earlier in the week but there was no mishap and the scenic bit of the tour was accomplished with ease.

At various points along the way, delegations of automobilists met the pathfinders and escorted them from time to time. Everybody seemed enthusiastic over the tour and numerous tentative entries were made by enthusiasts along the way. Good roads and the reasonable administration of just laws were the keynotes of the welcoming speeches delivered everywhere. Whenever the car crossed a state line, there was always a delegation awaiting to give greetings and good cheer.

The effect of the road building last year was still distinctly in evidence and the effort that is being made all along the route, indicates that before the tour starts, the course will be in good shape all the way from Atlanta to New York. In addition, many roads are now being hurriedly improved.

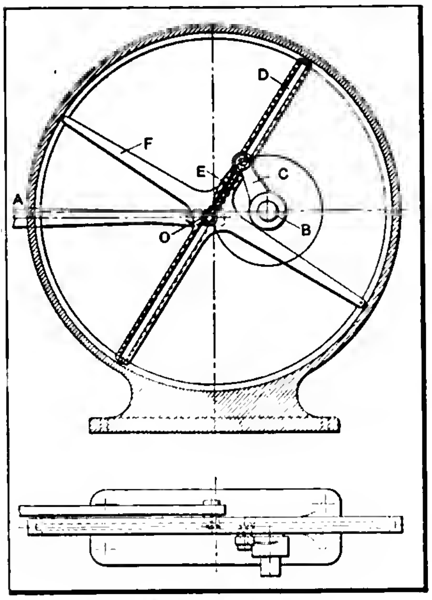
Passing the Historic Battlefields of Gettysburg, Pa.

Good Macadam Roads Among the Hills Near Staunton, Va.

Engineering Digest

A carefully abstracted digest of accounts of engineering activities as they are reported in society transactions and technical papers throughout the world.

A mechanical movement which might permit designers of four-cycle motors to realize a long power stroke, with complete expansion of the gases, in conjunction with short suction and compression strokes, is suggested by E. L. Doaré in *Revue Mécanique* for December, 1909. The expulsion stroke must of course be as long as the power stroke. The author is not sanguine with regard to the practical utility of his plan, but submits it for what it may be worth, and *La Technique Automobile et Aerienne* of February 15 presents it with more confidence in its practicability. The basic idea is to make the connecting-rod knuckle describe alternately a small complete turn and a larger complete turn, instead of two circles around the crankshaft axis. Means to this end is found in the Pascal snail curve described by the point *M* on the line *OR*, when the latter turns around *O*, and *M* is a constant distance from the point *N*, which is the variable point of intersection between the circle *W* and the line *OR*. While no shaft fixed at *O* can be used in a motor without interference with the crankshaft, which is represented by the center of the circle *W*, the point *O* can be fixed by means of a revoluble ring with a slotted diametrical member, the latter representing the line *OR*. In the illustration, *A* is the connecting rod, *B* the crankshaft, *C* the crankarm, *D* the slotted diametrical member, *E* a sliding member connecting the connecting-rod knuckle with the crankarm pin, and corresponding to the distance *MN* in the diagram. *F* is another diametrical member serving to brace the revoluble ring. It will be noticed that the slotted member turns only 180 degrees when the crankarm makes a complete revolution, and that the movement of the connecting-rod knuckle must be on the order of the double curve shown in the diagram. The mechanism devised would admit of only single-cylinder construction, for reasons which are made apparent by glancing at the plan view below.

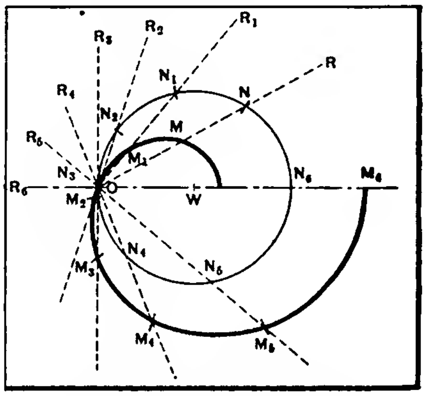


Doaré's Mechanical Movement

Diminutive electrical motors, which may be used for laboratory work, and perhaps for models of aeroplanes in connection with a diminutive rapid-discharge storage battery, engaged the attention of the members of the *Académie des Sciences*, as reported in the *Comptes Rendus* for this institution for April 11. Mr. Carpentier showed the members a dynamo which, so far as known, is the smallest that has ever been made, though its maker, a Mr. Trévet, thinks he could make one still smaller if put to the test. The dynamo is of the Gramme "superior type" and weighs 7 grammes, or 0.3 ounce. It is 15 millimeters in height and length and about 13 millimeters wide. The field is wound with wire of 0.05 millimeter thickness, silk-insulated, and carries 600 turns. The armature is keyed to a shaft whose bearings are only 0.5 millimeter wide, and measures itself only 6.02 millimeters in diameter. It is of the toothed type and in twelve sections. It is wound with 1.67 meters of wire 0.05 millimeter in diameter. The collector-ring and brushes are put together as those of large dynamos and composed of many pieces. The brush-holder is keyed adjustably. All pieces are assembled by means of screws, no solder being employed, and the whole little machine can be taken apart and put together like a standard dynamo. With a little pocket battery, Mr. Carpentier made the dynamo turn as a motor at the meeting. Idle, it turned at extreme speed, causing a buzzing like that of a large insect, and used 0.2 ampere at 3.5 volts, say 0.7 watt. Neither its work nor its speed could be measured.

Recent advancement in economy to be gained by the use of internal combustion motors in seagoing vessels is illustrated through the results obtained with the tug boat Rapido, built at the Krupp Germaniawerft at Kiel. The trials of this boat were witnessed by representatives of the German navy and by many shipbuilders and chandlers from other countries. The Rapido is 15.3 meters (50.20 feet) over all, has 3.6 meters (11.82 feet) beam, 1.15 meters (3.77 feet) draft, and a displacement of 20.7 tons. The motor is of Krupp design with self-ignition on the Diesel plan, and is reversible. At 400 r.m.p. the six cylinders develop 120 effective horsepower and produce a speed of 10½ knots. The towing pull at 6½ knots reaches 1,200 to 1,300 kilograms (2,645 to 2,866 pounds). The measured fuel consumption is 180 grammes (7.70 ounces) per horsepower-hour. The total weight of the motor with full running equipment is 4,400 kilograms (9,700 pounds). These figures compare well with those of stationary Diesel plants.

Considering that the towing capacity referred to is obtained with a displacement of only 20.7 tons, an important superiority in this respect is noticed over steam tugs, writes *Teknisk Tidskrift* of Stockholm for March. A steam tug with the same towing capacity would require a displacement of 50 tons, and the larger boat requires more power to move itself and must have a more powerful engine in order to tow as well. In calculating fuel cost, one should, therefore, compare the 120-horsepower crude oil motor with a larger steam engine, but even if similar horsepowers are compared, and it is assumed that steam consumes 1 kg. coal as against



One-Half of the Pascal Curve

180 grammes (7.70 ounces) of crude oil, a considerable saving is shown. If a ton of coal costs 16 kroner ($4.30) and a ton of crude oil 40 kroner ($10.75), without duty, and 72 kroner ($19.35) with duty paid, the fuel cost for steam will be 0.016 kroner per horsepower-hour (0.45 cent), and for crude oil 0.0072 kroner (0.2 cent), without duty, and 0.0139 kroner with duty (0.37 cent); in other words, a saving of 20 to 56 per cent., according to whether duty is paid or not. (For government use the duty need not be considered, of course, and the Swedish engineers evidently have this in mind.) Another advantage, especially for larger vessels, lies in the reduction of personnel. Stokers are dispensed with, and this about balances against higher cost for attendance and maintenance. These advantages and the larger radius of action for the vessel with oil motor, appear most clearly by comparison of the engine plants of larger vessels. Suppose a freighter of 7,500 tons and of 2,500 effective horsepower makes 11½ knots. With a steam plant, such a vessel uses in 24 hours about 45 tons of coal and, with 2,000 cubic meters of bunker space, has a radius of about 12,000 nautical miles. The same ship equipped with crude oil motors uses under similar conditions 13 tons of crude oil. The radius is increased to 38,000 nautical miles, i.e., more than tripled. Equalizing the radii, the oil motor boat can take in freight its saving in fuel space or weight. In the example used, the additional cargo would be 1,350 tons, or a gain of 18 per cent. over steam assuming that both power plants are of the same weight. In reality, the oil motor plant can be built lighter than a reciprocating steam engine plant. The economy of the oil motor in operating cost comes under the heads of fuel, wages and materials for maintenance and lubrication, and amounts, for a voyage of two weeks' duration, for vessels such as referred to, to 2,700 kroner ($726), the operation of the steamboat costing 10,800 kroner ($2,903), and that of the oil-motor vessel 8,100 kroner ($2,177). While the first cost of oil motors exceeds that of a steam plant and calls for higher disbursements for interest and sinking fund, this is compensated for in the shorter wharfage time, since the crude oil is more easily taken aboard than coal, and also by saving in fuel for firing up and keeping up steam. Calculating that a vessel yearly makes 18 voyages of two weeks each, a total saving of 48,600 kroner ($13,037) is effected in cost of operation alone, to which should be added the gain resulting from the 18 per cent. addition to the freighting capacity. Apart from economical advantages, the absence of smoke should militate in favor of oil motors, especially for passenger boats and naval vessels, and the reduction of heat radiation, which is a source of trouble and sickness of the crews in steamships, especially in the tropics, should be considered. Even if the foregoing figures, concludes the Swedish commentator, are not yet realized for large vessels, they show the economical superiority of the large oil motor plant and furnish an argument for producing larger and larger motors so that the internal combustion motor industry may gain the place in seagoing transportation to which it is intrinsically entitled.

Many microphotographs of welds are presented in an article by Ch. Fremont appearing in *Le Génie Civil* for February 26. While dealing largely with the welding of boiler plate, with special reference to the accidental explosions which have taken place in the French navy vessels, the author arrives at the general conclusion from facts of record that riveting is always superior to hammer welding and hammer welding always superior to autogenous welding, under equal precautions for securing competent workmanship, and also that the fact that a weld has endured the normal stresses to which it is subjected for a number of years, affords no guarantee whatever against a sudden rupture. Electrical welding is not considered in the article.

M. B. Galitzine, of St. Petersburg, Russia, presents an illustrated description of a simple apparatus for measuring the horizontal and vertical tremblings of a building caused by the operation of a four-cylinder Diesel motor in an adjacent factory. *Comptes Rendus de l'Académie des Sciences*, April 11.

So as to have each automobile provide its own dust protection, Franz Ragaller, coppersmith to the Court of Bavaria, at Munich, has designed and executed a water-sprinkling device for automobiles comprising two oblong reservoirs to be attached under the running boards on both sides of the vehicle, a system of discharge valves and ingenious shields preventing dirt and dust from clogging the apparatus. The reservoirs hold 50 to 100 liters, according to the size of the car to which they are to be attached, are divided by bulkheads to obviate swashing and have bottoms sloping slightly to both ends to facilitate the feed of the water to the sprinkling roses. The feed may be regulated by means of self-closing slides in the discharge pipes which are controlled from a battery at the driver's seat. *Allgemeine Automobil Zeitung* for April 22 states that the device wets the tires and that the latter, therefore, raise no dust and leave a moistened and dustless track, but does not explain in what manner the water reaches the front portion of the front wheels before the latter strike the dry road before them.

Under the misapprehension that motors for aeroplanes should be required to work constantly close to their maximum capacity, and that 70 to 80 degrees centigrade should, therefore, be the highest temperature which the cooling water in an aeroplane motor should be allowed to reach, German manufacturers have gone into the otherwise laudable enterprise of producing radiators with a higher capacity for a given weight than is possessed by the standard automobile radiator. Erwin Aders describes the methods adopted to this end in *Der Motorwagen* for April 10, with illustrations of the construction parts. With the use of the customary materials, the desired cooling capacity could not be accomplished at less than a weight of 1½ kilograms per horsepower, and reduction of the gauge of the sheets and pipes is excluded by reason of the porosity of the metals. A change to aluminum is indicated, because this has a specific gravity of 2.75 against 8.5 of brass, and a conductivity of 175 against only 55 to 110 for the brasses. As, however, aluminum cannot yet be soldered with the same assurance of a good job by simple work methods, the true cellular types of radiators are not available, and aluminum radiators must be of the vertical pipe pattern. In one case, holes are stamped in aluminum sheets 5 millimeters in thickness, and the ends of aluminum tubes are expanded into these holes, somewhat as the fire flues are secured in boilers of certain steam vehicles. The necessity for leaving enough material between the holes reduces the weight-saving accomplished in this type. In another type, in which the tubes are flattened except at the ends the design is similar to that seen in Renault cars of the older models, and the bottom of the lower, as well as the cover of the upper water-containers, is removable, forming part of a frame composed of four tin plates braced by diagonal wires. The construction, so far, is expressly intended for aviation motors only.

Looking ahead for the revolving engine is the title of a masterly editorial in the May 7 issue of *The Autocar* (English), in which the writer takes up the reasons for the success or failure of various types of engines, as exemplified in the automobile business. Following this, he reverts to the present state of aeronautics, and deduces the idea that, first, the aeroplane owes its ability to fly, its very existence, to the automobile engine, but beyond that the revolving cylinder type of engine is the best one and the one that will be most used in the future. He arrives at this through a consideration of Messrs. White and Paulhan in their competition for the English *Mail* prize. Some of the statements made are of sufficient interest to warrant reproduction. The writer says in part: "The flying machine owes its ability to fly to the motor-car engine. Now, it seems as though it might repay its debt to the light car by the evolution of a type long since discarded by the motor-car builder, though indirectly he has made its use possible by the improvements in material, design, detail, and workmanship which he has brought about in the past ten years. The ideal engine is the gasoline turbine though that is far away.

Questions That Arise

A series of practical questions relating to the automobile, its parts, and their functions, which arise upon various occasions, together with easily understood answers to the same.

[1]—What is the relation between piston velocity in feet per minute and angular velocity of the crankshaft in revolutions per minute?

Taking the crankshaft velocity as 1,000 feet per minute for the maximum safe practice, the speed in revolutions per minute, referring to the crankshaft, may be found as follows:

$$S = \frac{F}{\left(\frac{s \times 2}{12}\right)}$$

When,

S = crankshaft speed in revolutions per minute.

F = piston speed in feet per minute.

s = stroke in inches.

Fixing the piston speed at 1,000 feet per minute, and the stroke at 6 inches, the crankshaft speed will be 1,000 revolutions per minute, since:

$$S = \frac{1{,}000}{\left(\frac{6 \times 2}{12}\right)} = 1{,}000$$

In the same way, any other crankshaft speed may be ascertained for any other assumed piston speed, for any given stroke.

[2]—Why is it necessary to limit the piston speed to 1,000 feet per minute as a maximum?

It is not necessary, but it may be desirable. The piston speed of a motor, if counted, in some measure, for several reasons, reflects the life of the motor, and the adequacy of the service it will be likely to render. In racing, the speed frequently goes up to 2,000 feet per minute, and under touring conditions, the probabilities are that the average piston speed, for all-day performance, is inside of 500 feet per minute. In a general way, the strain to which the motor is subjected, considering these differences in piston speed, is in the ratio of 1 to 16. Obviously, the racing condition, if it puts the motor under 16 times as much strain, is bound to reflect seriously upon the life of the motor, whereas, under touring conditions, the life of the motor will be very much longer. The question then, of what the piston speed should be, as it is ordinarily measured in feet per minute, is one which must be solved, in view of the effect of speed upon depreciation, and the right piston speed will be that which will limit the depreciation to, say, 10 per cent., or some other acceptable value.

[3]—What is the relation of torque to power of a motor?

The force of the twisting moment or torque is a measure of the power of the motor, the relation being as follows:

$$H.P. = \frac{2\pi R S P}{33{,}000}$$

When,

$$2\pi = 6.28$$

R = radius of the lever arm in feet at the end of which the force P in pounds acts.

S = speed of rotation in revolutions per minute.

P = pull in pounds (representing the torque or twisting moment) at the end of the lever arm of radius R.

H.P. = Horse Power.

33,000 = the number of foot pounds said to represent 1 horsepower.

Transposing,

$$P = \frac{H.P. \times 33{,}000}{2\pi R S}$$

[4]—Is the torque of a motor constant, irrespective of speed?

Theoretically, yes; practically, no.

[5]—What are the reasons in practice for torque modifications?

Since the torque of a motor is an expression of the energy set free when the mixture is ignited, and since the force of the explosion, so called, is modified (a) with changes in the weight of fuel utilized (b) with changes of compression, the conditions as follows must be recognized. The compression will be lowered when the motor is running slow, because there will be more time for mixture to leak by the piston rings, and there will be more time for the heat to pass away through the cylinder walls to the water in the water-jacket, thence to the radiator, where it will be absorbed by the passing air current.

Increasing speed also has its effect upon the torque, and beyond a certain range in the speed for any given motor, the torque decreases with further increases in speed, due to wire drawing as the mixture passes through the valves, a depression in the intake, due to the small size of the same, and back pressure in the exhaust manifold, for the same reason. There are other pumping loss factors which will have to be taken into account in a closer examination of this phase of motor operation, but these are conspicuous reasons for a modification of the torque characteristic of a motor.

[6]—If it is true that an intake depression reduces the power of a motor through its modification of the torque characteristic, and if this condition obtains because the intake is restricted, why is it not proper to enlarge the same and obviate this difficulty?

Within prescribed limits, the remedy lies in having the intake large, of suitable contour, and with a perfectly smooth bore. In view of the fact, however, that the intake valve opens before the flame is quenched in the combustion chamber, popping back must be guarded against, and this troublesome difficulty is only to be overcome if the area of the intake is such that the speed of travel of the mixture en route to the combustion chamber is higher than the rate of flame travel in the mixture itself. If the flame propagates through the mixture at a rate so fast that it will overtake the stream, combustion will take place in the intake manifold instead of in the combustion chamber and in this way the so called "popping back" difficulty is brought about.

[7]—If the torque of a motor decreases with increasing speed for reasons which are unavoidable, is it not a fact that the power of the same motor will decrease with increasing speed?

As the formula indicates, the power of a motor is proportional to the torque on the one hand, and the speed on the other. Power, then, is represented by torque multiplied by speed. The best power of any motor is found in the range of its speed at which torque time speed finds its greatest value. If the speed is very high, the torque may be relatively low for a given power; if the speed increases at a rate higher than the rate of decrease of the torque for speed, the power will be increasing with the speed, or, if the torque remains constant, power will be in direct proportion to speed. Conversely, if the speed is held constant, the power will change in direct proportion to torque changes.

[8]—To what extent are these changes to be noted in practice?

Considering automobile motors in average practice, the best condition seems to obtain when the piston velocity is between 800 and 1,000 feet per minute.

[9]—How hard should a valve spring press the valve against its seat?

There is no fixed rule for this; the pressure should be measured in pounds per square inch. It is claimed that 40 pounds per square inch will suffice for every need.

[10]—Why should the pressure be measured in pounds per square inch?

After a valve closes, which it does in response to the pressure exerted by its spring, all that remains to be done is for the valve to stay on the seat with sufficient firmness to assure that it will be tight against leakage. Despite this relatively slight duty, the situation is one demanding some pressure, for the reason that the suction tends to open the exhaust valve, due to the depression in the combustion chamber (cylinder). The amount of the depression, as measured in pounds per square inch, demands that the pressure exerted by the valve spring be more than the suction per square inch, and that this pressure on the seat by the valve be in like value, i. e., in pounds per square inch. In addition to the overcoming of the depression, it is necessary for the pressure of the valve on the seat to be enough to squash down any foreign substance that may find lodgment there, and in addition, it is necessary to squeeze excesses of oil off of the surface in order that the valve may seat; it is probable that 40 pounds per square inch is adequate for the purpose.

Were the pressure measured in pounds, independent of the area of the seat, it is possible that the pressure in pounds per square inch would be below the requirement, due to the fact that the depression in the cylinder, as measured in pounds per square inch, would be so great that the pressure on the seat, resultant of the ability of the spring, would be below the requirement, and the valve would not then press against the seat enough to assure tightness.

[11]—Why is it that conical valves are so much used?

Considering the question of the pressure, which is exerted by the valve spring, the conical seat offers certain advantages; a spring of a given strength, working against a conical seated valve, is favored by the wedging acton, due to the shape of the seat. In addition to this is the fact that the foreign substances which may find lodgment on the seat during the time the valve is opened will be scraped off as the valve is closed; this action cannot take place when the seat is flat; in a flat-seated valve, under the circumstances, the foreign substances must be pulverized, and even then they may not be driven out from under the seat, and a leak will result. There is also danger of damaging the flat seat if foreign substances find lodgment there; when the valve closes under the action of the spring, the seat pressure is enough to drive any hard substance into the metal of the seat, and in the course of time it is possible that the seat will crumble away, just as asphalt pavement does, as the direct result of small surface blemishes, they being made by the cauks of horses' shoes.

[12]—What are the advantages of flat-seated valves?

They open freely, due to the absence of wedging action. The effective area is greater, considering a given outside diameter of the valve. The area of the rest remains constant even after repeated grindings.

[13]—Why not regard these advantages as well worth having in every motor made and used?

All roads lead to Rome! As an answer, this fixed phrase may not be sufficiently clear for the purpose; it may be supplemented by the further statement that (a) the wedging action of conical valves is not sufficient to serve as a detriment; (b) the difference in area between the flat and the conical seat is not enough to make it difficult to have the conical seated valve as much larger as the difference may indicate; (c) the increase in area of the conical valve, while it may ultimately have to be corrected, is at such a slow rate that it is a matter of several years' service before the trouble will become emiuent, and, even when it does come up for treatment, it is easy to deal with; against this is the fact that the conical valve has certain advantages which are well worth considering when a decision is being made.

[14]—What other qualifications must the valve spring have?

Besides closing the valve, there is the necessity of doing so as quickly as possible. If the spring is not sprightly the cam-roller will not hug the cam, and noise will result. In addition to this, unless the spring closes the valve as quickly as the cam will permit, as it engages with the roller, the timing will go awry. There is no use of going to the trouble of timing the opening and closing of the valves unless the springs will act as quickly as to serve for the intended purpose.

[15]—How soon should the spring close the valve?

The exact time depends upon the requirement as fixed by the designer of the motor in view of the service to be rendered. This question, however, has for its scope the idea that the valve may not be closed, excepting after a certain time has elapsed, due to inertia of the reciprocating mass; the closing should take place within the time taken for the camshaft to rotate 20 deg.

[16]—What has inertia to do with the closing of a valve?

Accordingly as the valve is increased in weight, the inertia factor will increase, and the greater will the time of closing the valve be, considering a given strength of the spring placed to do the work. If the valve-lift is also operated by the spring, it, too, will have to be taken into account.

[17]—What is inertia?

It is the property of a body by virtue of which it tends to continue in a state of rest or motion in which it may be placed, until acted on by some force.

[18]—What are the laws to which inertia responds?

Newton's laws.

[19]—What are Newton's laws?

There are three to which reference will be made as having bearing upon this matter:

(a) Newton's first law: If a body be at rest, it will remain at rest; or if in motion, it will move uniformly in a straight line until acted upon by some force.

(b) Newton's second law: If a body be acted on by several forces, it will obey each as if the other did not exist, and this whether the body be at rest or in motion.

(c) Newton's third law: If a force acts to change the state of a body with respect to rest or motion, the body will offer a resistance equal and directly opposite to the force. Or, to every action there is an equal and opposite action.

[20]—What is it that causes the valve of a motor to open?

Force.

[21]—What is force?

It is anything that tends to change the state of a body with respect to rest or motion. If a body is at rest, as when a valve is on its seat, anything that tends to put it in motion is a force. If a body is in motion, as a valve which is being opened, anything which tends to change either its direction or its rate of motion, is a force.

[22]—Why is it that some motors work better than others?

It is very rarely that the principle is at fault. Design, construction, material, and method of use, more frequently have to do with poor result.

Aligning Automobile Wheels

Editor THE AUTOMOBILE:

[2,264]—Will you please tell me in your next issue of "The Automobile" the best way to tell if the four wheels of an automobile are in alignment. A. S. GARDNER.

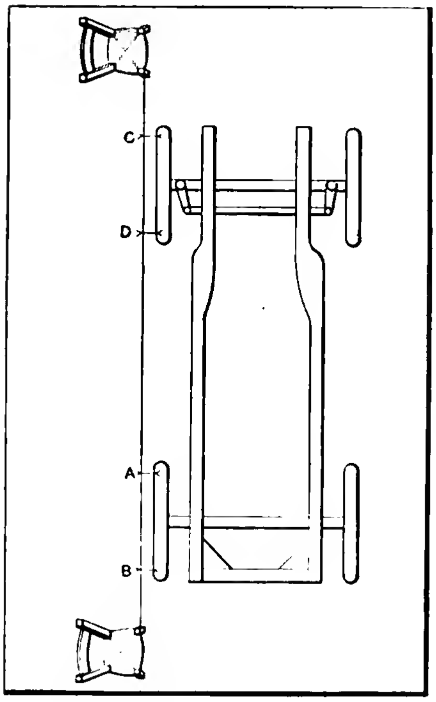
Yazoo City, Miss.

Two drawings are shown on this and the opposite page to show how this is done. First line up the wheels on one side, and then in combination with this line up the wheels on the opposite side. Take the car in any position, in the middle of a flat floor of good area, turn the front wheels as straight as possible. Set a pair of chairs on the floor facing the car, one about two feet in front of the car, and the other perhaps two feet back of it, but both so placed as to be close to an alignment with the side of the wheels, as the figures show. Stretch a string, cord, or wire from one chair to the other, being careful to maintain the same height above the floor at all points. Measure from this string or wire as a datum line to the front and rear parts of the front and rear tires. In case the distance from the front wheel to the datum and that from the rear wheel to the datum line differ, move one end or the other until the two measurements agree exactly. The datum line is then exactly parallel to the line of the wheels on that side.

Now, with a second pair of chairs and a string or wire, repeat the performance on the other side, obtaining another datum line there which is exactly parallel to those two wheels. Having done this, measure across from the one datum line to the other, both at the front, as A, B, and at the rear as C, D, taking care to measure these two at equal distances from the wheels, that is, the distance D H should equal the distance in front at B E.

Should these two measurements agree exactly, the wheels are in alignment, but should one measurement be longer than the other, they are not and a correction should be made. It is well to check up the squareness of the rear axle with the two lines, at the same time, which may be done by dropping a point from the center of the two hub caps, and drawing a cross line through these two points.

Having this cross line, which represents the center line of the rear axle, drop also lines representing the two parallels just found. Then measure the angle of the rear axle line with these. It should be 90 deg.



Method of Aligning One Pair of Wheels

"Steering Advantageously" Revised

Editor THE AUTOMOBILE:

[2,265]—It may be presumptious on the part of a modest driver of only one season's experience of 6,000 miles to venture to differ from recognized experts such as those who conduct "The Automobile," yet "fools rush in where angels fear to tread" and I dare to be one of those fools. Let me say in preface that I will take with the utmost good nature any criticism from you, and further, if you deem this screed worthy of publication, I request that my name be omitted. I am not ashamed of it, but prefer to remain, like all other great people making incursions into foreign territory, "incognito."

That which has called forth this space-wasting contribution is your comment on page 581 in the issue of March 24 on "Steering Advantageously." I must admit that I have never seen a race, and am therefore arguing from theory and possibly thereby laying myself liable to all sorts of justifiable attacks upon my attitude

As it seems to me, the racing driver and the pleasure driver are not to be classed together.The race driver is operating over a course every foot of which he knows and every turn of which he has negotiated in advance and every known contingency in which he has been able to study and provide for. When the actual race comes the unknown quantity is the presence on the track of his competitors and the complications which may arise therefrom. Under ordinary conditions he has only to keep his car steady on the straight stretches and negotiate the turns under the circumstances which seem to him most advantageous, and except at turns, and not always then, he has little or nothing to do with spark or throttle; both are wide open in the position which will do him the greatest good. Understand, please, that I am not attempting to underrate the skill, nerve and coolheadedness which are required in race driving. No reward of which I can conceive would tempt me to try it.

The pleasure driver faces conditions which are constantly varying. Occasionally he reaches long stretches where he can lie back at ease and assume the race driver's position, and under certain circumstances that position is undoubtedly the best, but in a day's drive of 100 to 125 miles, which is all that any ordinary pleasure driver ought to attempt, he is occupied the greater part of the time in meeting varying conditions of direction, grade, speed and highway surface so far as his own car is concerned, and of the occupancy of the road by other vehicles going in both directions and by the crossing of the road by pedestrians. I have been told on reliable authority that the racing driver shrinks from driving through crowded city streets, preferring to let some other hand take the steering wheel, and I can readily believe the statement. The method of steering which has given me the greatest comfort is that in which both wheels are placed in front of a line across the car at right angles, one hand being very near the front and the other about 45 degrees forward of the cross line, that is, with both hands above the forbidden horizontal center. The left hand grasps the wheel firmly and does the greater part of the work. In cases of emergency it can control the greatest average deflection both ways. With the thumb of the right hand for the spark and the forefinger for the throttle the movements of these two essential levers are easily controlled and the other fingers can grasp the wheel lightly and aid the left hand. In addition the right forearm lies across the wheel, affording a rest to that member. As I noted before, when long, straight stretches are met, both hands can be dropped to the race driver's position, affording a welcome variation.

It should be remembered also that the race driver is not hampered by any considerations of economy of fuel or solicitude for the welfare of his car, points which are ever present with the careful pleasure driver.

It must not be forgotten that this is a matter into which the personal equation enters very largely and that the position which I have found to be the best for a long day's run may not meet the requirements of someone else.

As a former newspaper man of more than twenty years' experience I know the value of time and space; yet there are times when even an old newspaper man becomes prolix—"garrulous," if you choose to put it that way; and this seems to be one of those times. For which I ask your pardon.

Boston. LEIGHTON.

Despite the fact that a racing driver has been over the course on which he is driving and should know it perfectly, the speed at which he is traveling makes his case a parallel one to that of the driver who is traveling over unknown roads but at a very moderate speed, being thus able to stop quickly, whereas the racing driver stops after the accident, sometimes stopping only when heaven is reached. This being the case, the argument above is upset.

Still Starting on the Spark

Editor THE AUTOMOBILE:

[2,266]—I am at present a subscriber to your valuable journal and have been for several years past. I wish to say in regard to Starting on the Spark, letter 2,201, that it is not impossible to remove plugs or open pet cocks, and then start on the spark. While I readily agree that this cannot be done with any certainty, I have done so on a few occasions. Another test I wish to call your attention to is: Start up the motor, run till it has warmed up a little, open the pet cocks, inject gasoline into the cylinders, and then try starting on the spark. A trial or two will demonstrate this to be a thing that can be done occasionally. Now, as to compression, I realize that it is absolutely necessary to the proper working of a gas engine, but here is a little story along that line. This has to do with a friend and his car. He never drove a car until he purchased a popular priced thirty-horsepower machine last June. You know how a novice usually handles spark and gas; it was true in his case, late spark and open throttle. We all know what this does to valves. Now up to the present date he has covered over six thousand miles without touching a valve. You will agree that they are bound to be leaky; it is impossible that they should be otherwise. Last Wednesday I looked over his car, enriched the mixture, and it now starts on the spark, but his valves will be ground in to-morrow. F. M. GIVENS.

Bayonne, N. J.

No comment on the above letter is necessary, except to state that when it was said that starting on the spark was nearly impossible, the average case was referred to and not the three-times-in-three-years case, or anything of that sort.

Blower Pressure and Strong Metals

Editor THE AUTOMOBILE:

[2,267]—Please answer the two following questions, both of which have reference indirectly to a new type of automobile engine that I am building: About what pressure can be obtained from two fans 18 inches diameter, similar to the kind used on automobile engines, attached to the same shaft, each one enclosed in a separate casing, but the first drawing from the open air, while the second draws from the outlet of the first, the two fans being driven at the same speed? What strong metals will withstand a very high temperature, say 400 to 1,000 deg. C.?

New York City. M. E. M.

A fan two feet in diameter (24 in.), will, at 600 revolutions per minute, deliver about 5,000 cubic feet of air per minute. This velocity is approximately equal to a pressure of 1 oz. per sq. in. As the first fan would deliver the air at this pressure to the second fan, the latter may be expected to raise the pressure starting from that point in about the same ratio, namely about 60 to 1. This would give a resulting pressure at the outlet of the second fan under favorable conditions of about 60 oz. or roughly 4 lbs. It must be remembered in this connection that this is a matter in which even experts sidestep direct figures.

Steel is a strong metal, so too, is manganese bronze, and in a relative sense, cast iron. All of these will withstand the temperature mentioned.

Horsepower Formula Once More

Editor THE AUTOMOBILE:

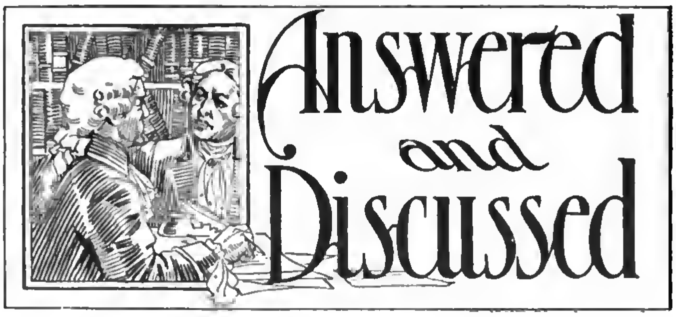
[2,268]—Please answer me through your question box, giving the formula used at the present time, that is, the generally accepted one, for figuring the horsepower of gasoline automobile engines. LOYD H. JORDAN.

Gordon, Neb.

That formula known as the R. A. C. or A. L. A. M. is now in general use. It is:

$$\text{Power} = \frac{D^2 N}{2.5}$$

this rendered into words is the square of the cylinder bore times the number of cylinders, divided by 2 1-2. Apparently it does not consider the stroke, but it is based upon a piston speed of 1,000 ft. per minute, so that longer strokes would yield the same amount of power but at a slower speed, according to it. This latter point has caused much confusion in the use of the formula.



Cranes Made in New Jersey

Editor THE AUTOMOBILE:

[2,269]—In "Letters Interesting" could you give me some information about a car called the Crane, made at Bayonne, N. J.? I have looked in vain through recent issues of "The Automobile" and "Motor Age" for a description of this car, and as it appears to be a first-class machine, I would like to know something about it. J. J. IDE.

New York City.

Unfortunately, this car has never been called to the attention of THE AUTOMOBILE previous to this, and so we have no information whatever about it. Any of our readers who have may send in such information, and THE AUTOMOBILE will be glad to publish it.

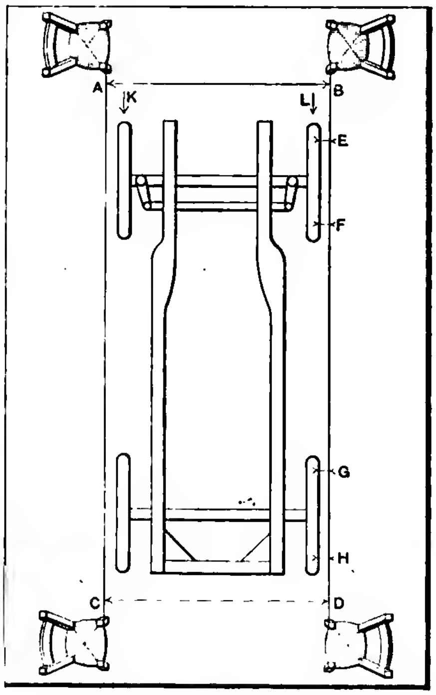
New Engine for an Oldtimer

Editor THE AUTOMOBILE:

[2,270]—I have a little car with a cone-cylinder engine of 3 1-2-inch bore and 3-inch stroke. It has 28-inch wheels, and is geared down 3 to 1, so that 3 turns of the crankshaft give one of the rear wheels. The engine is four-cycle and air-cooled. Could I put in it a new engine with two-cylinder 4-inch bore and 4-inch stroke, air cooled, and get good results? My car is a Crestmobile, model D, shaft drive. The firm making this car originally is now out of business, having failed. WILLIAM P. GILMAN.

Franklin, Pa.

Unfortunately, not enough detail about the construction of the car is given to enable one to state intelligently whether the new engine would go into place or not. If this can be proven to the owner's satisfaction, doubtless the extra power from the larger engine would not be sufficient to do any damage, that is, if the engine can be put into the old chassis, the transmission parts back to the rear wheels will doubtless carry the additional load in a proper manner. A single thought in this connection is that the new engine would require more fuel in any given length of time, this meaning new gasoline tank of large capacity, while the engine itself and all of its accessories will add weight. The result may be to add more weight than the small tires will carry. This should be looked into very carefully before making the change as tire depreciation and repair form a very large part of the motorist's weekly bill, and not the most pleasant part.



Completing the Alignment of all Wheels

Some Leading Magneto Details

By HERBERT L. TOWLE

IN last week's article were explained the principles of action of the three leading types of geared magnetos, i. e., low tension, low tension with separate coil, and high tension, properly so called.

Before taking up the different commercial types of magnetos it will be best to present the above mentioned classes in simplified form. By this means the different details of armature, interrupter, distributor, etc., will be more easy to understand.

In Fig. 1 is shown a typical H armature core, together with the bronze heads, *B B'*, which are screwed to it, and the shaft ends *A A'*, driven and riveted into the bronze heads. As the shaft is not continuous, the open spaces *C C'*, at the ends of the core are available for the coil windings. It will be seen that the core is not a solid casting; rather it is a pair of castings between which is clamped a group of soft iron stampings *D* having the form shown in the detail sketch. The object of thus laminating the core, as it is called, is to retard the circulation of "eddy currents" in the core due to induction. The same forces of induction which are at play in the windings operate also in the iron core itself, and if unchecked would both consume power and heat the armature unduly. As the voltage of these currents is very low, even the slight obstruction of the laminations is sufficient to retard them.

The bronze plates *B B'*, are not intended to be disturbed outside the factory. This is essential, as such disturbance would probably result in breaking the wire leading from the coil through the hollow shaft *A* to its outer end. It would also be likely to result in the shaft ends not being perfectly aligned when reassembled. Owing to the extreme care that must be taken, first in insulating the core, then in winding it, then in baking the coil to expel extra moisture from the insulation, and finally shellacking it to make it permanently watertight, it is essential that the work shall not subsequently be touched by unskilled hands.

Fig. 2 shows how the low-tension armature of Fig. 1 appears when completed and in place. The coil windings are bound around with brass wires laid in grooves in the core to prevent the coil from expanding from centrifugal force and striking the pole pieces. Before the necessity for this precaution was fully understood it was not unheard-of for armatures to "burst" or "swell," with the result of tearing or chafing away the outer wires of the coil, which of course put the magneto out of service till repaired. The inner end of the coil (not shown), is connected permanently to the iron core. The outer end is led, heavily insulated, through the hollow shaft to an insulated steel or copper button at its end, against which bears an insulated hardened steel button under the pressure of a spring. The mounting containing the steel button or collector is insulated from the rest of the magneto, and a binding post on it affords connection for a wire which carries the current to the bus bar on the engine. The ground connection to the switch is attached either here or to the bus bar. Closing the switch, it will be remembered, short-circuits the armature by giving its current a

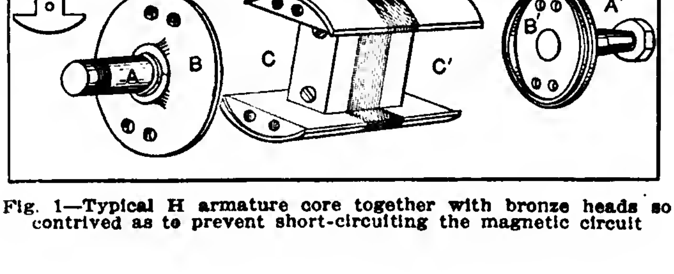


Fig. 1—Typical H armature core together with bronze heads so contrived as to prevent short-circuiting the magnetic circuit

direct path to "ground," i. e., to the engine and magneto frame, through which it returns to the inner terminal of the coil.

The ball bearings in which the shaft runs are supported in bronze plates screwed to the pole pieces. An aluminum or bronze plate closes in the bottom, and a cover plate over the armature between the pole pieces protects the armature from dust. The driving end of the shaft is tapered to receive a pinion, and the latter is jammd home on the taper by a nut, and usually keyed as well. The ball bearings are oiled about once a month. Other care is seldom if ever required. Before ball bearings were adopted it was customary to use plain bearings, which required frequent oiling, and sooner or later wore so loose as to permit the armature to strike the pole pieces. With ball bearings the clearance may be reduced to a few thousandths of an inch without danger of striking, thereby minimizing resistance to the lines of force.

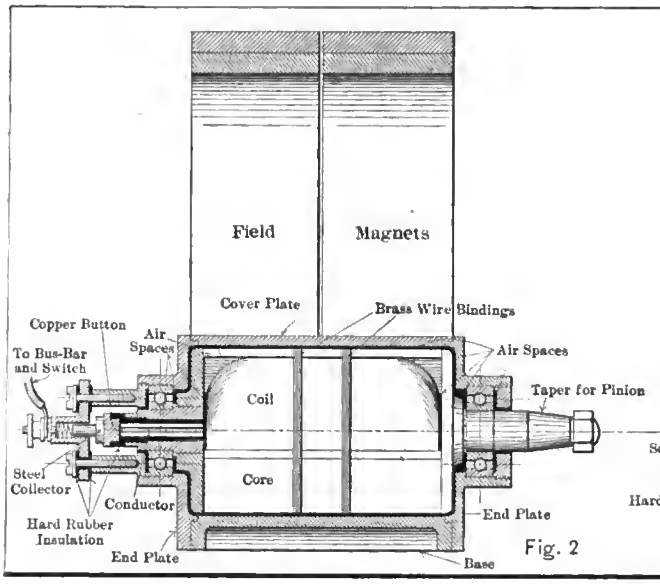
The average magneto user, it may be remarked in passing, does not realize the importance of giving the lines of force of the field magnets an easy path. It is well known that a common horse-shoe magnet becomes weaker if deprived of its "keeper." The same applies with even more force to the magneto. It is not even desirable to run a magneto with the armature circuit open, and this is one reason for short-circuiting the armature to interrupt the spark. When the armature is in position it affords a good path for the lines of force. If, however, it should ever be necessary to take out the armature for the purpose of repairing, this must never be done until a substantial plate of soft iron has been laid on top of the pole pieces; and the plate must not be removed till the armature has been re-inserted.

The magnetizing of the field magnets is an intricate problem, not so much to render them strongly magnetic for a time as to persuade them to retain their magnetism indefinitely. Certain steels refuse altogether to come up to the proper standard in this regard, and in fact most of the successful field magnets now used are made in Europe from foreign steel. When they come to this country they are "aged" to determine whether or not they hold their strength. If not, and if re-magnetizing does not cure the trouble, they are rejected.

Turning now to the second type of geared magneto, namely, the low tension type with separate coil, we find it a little more complicated than that shown in Fig. 2. It will be recalled that in this type the armature is short-circuted just before the spark is desired, and that breaking the armature short-circuit causes an extra current to flow through the primary winding of the induction coil. This winding has a high resistance in order to compel the bulk of the armature current to flow through the short-circuit till the latter is broken. In addition to the elements shown in Fig. 2 two others are necessary, namely, a mechanical interrupter for short-circuiting the armature at the proper time, and a high tension distributor whereby the secondary current from the coil is delivered to the spark plugs in order. The distributor for a 4-cycle engine is driven from the armature by gearing with two to one reduction.

The interrupter is simply a device for making and breaking the armature circuit, once for each explosion or twice per revolution. Interrupters are of numerous forms, but in all of them a pivoted lever carries a platinum contact point normally abutting against a platinum-tipped screw, and a moving cam striking the lever causes it to break contact. Frequently the cam is stationary, and the lever with its mounting revolves with the armature. The contact screw is insulated and current is led to it by an insulated screw or other conductor through the armature shaft.

One form of interrupter is shown in Figs. 3 and 4, the latter giving an end view of it with the cover plate removed. The cams are stationary and the interrupter mounting, called the



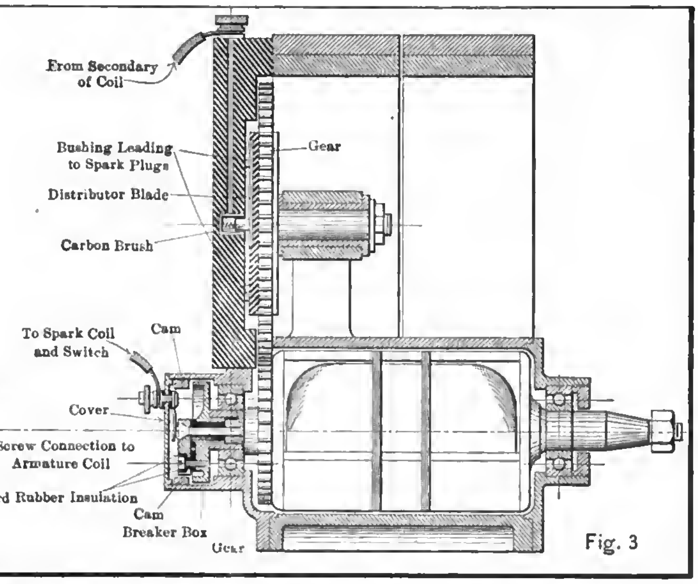


Fig. 2—Section of a simple form of low-tension magneto as used in conjunction with a high-tension coil. Fig. 3—Section of a geared type of magneto with means for short-circuiting just before the current is delivered

"breaker box," is attached to the armature shaft. A spring holds the platinum points normally in contact, and they are separated when the small end of the lever runs over the cams. An insulated spring contact leads the momentary extra current to the primary winding of the outside spark coil, the other terminal of the coil being grounded. To cut off the spark the coil is short-circuited.

In the distributor shown in Fig. 3, the high tension current is led to the top binding post and thence to the central carbin brush, which bears against a radial brass strip, called the distributor blade, embedded in the hard rubber disc attached to the large distributor gear. This blade runs in order under four other carbon brushes spaced equally around a circle and leading current to the spark plugs through connections not shown.

We next come to the high tension magneto, Fig. 4. It has the same form of armature, field magnets, and interrupter, as that in Fig. 3. The distributor may also be similar, though that shown is a little different for the sake merely of illustrating another type. The armature coil of course is different, having a small primary winding with a heavy secondary winding outside of it.

The high tension magneto contains two new features, namely, the condenser and the high tension collector ring. The condenser is usually, though not necessarily, located on the armature shaft in order to get it as close to the interrupter as possible, and it is there shown in Fig. 4. In some magnetos, for the sake of greater accessibility and other reasons, the condenser is located outside the armature in a stationary sealed box.

The high tension collector ring performs for the high tension current the same function that the copper button at the end of the armature shaft in Fig. 2 does for a low tension current. That is to say, it permits the high tension current to be taken off and led to the distributor. The collector ring is of hard rubber with a brass ferrule surrounding it, against which ferrule a heavily insulated stationary carbon pencil bears. The hard rubber spool has wide flanges for the purpose of preventing the high tension current from escaping, by giving it a long path to travel from the brass contact ring to the shaft. As hard rubber is much more resistant than air the current tends to travel over the surface of the spool instead of striking through it. From the carbon collector brush the current is led through a suitable conductor to the center of the rotating portion of the distributor—in this case through a spring and a carbon pencil projecting from the distributor shaft, which is hard rubber with a metal sleeve over it for bearing purposes. Instead of the flat distributor blade of Fig. 3 we have a carbon distributor brush pressed radially outward by a spring and running against the inner surface of a hard rubber ring, in which are inlaid the contact segments from which the current goes through suitable terminals to the spark plugs.

A feature of high tension distributors, which is not shown in these drawings, is the safety spark gap. This is a spark gap between insulated metal points, one in the high tension circuit, and the other grounded. If for any reason the high tension current should exceed the safe voltage (e. g., if the spark plug cables were to be disconnected), the spark would jump the safety gap and thereby prevent the secondary voltage from becoming so high as to endanger the insulation of the coil. The distance of the gap is about one-quarter inch.

Although the illustrations herewith show the essential elements of the three principal types of geared magnetos, they must not be taken to show actual construction very closely. Numerous details making for better insulation, protection against oil, water and dirt, ready accessibility, etc., have purposely been omitted in order to make the drawings so simple as to be easily understood. In a later article will be given illustrations of actual commercial magnetos. By comparing these future illustrations with those given herewith, the reader will be able to identify the various parts without much difficulty.

In order to be able to follow the trend of the articles as they will discuss magnetos of the various commercial forms, it will be desirable to study this article, and thereby become accustomed to the methods of connecting up, as well as the reasons for doing so in the several ways talked about.

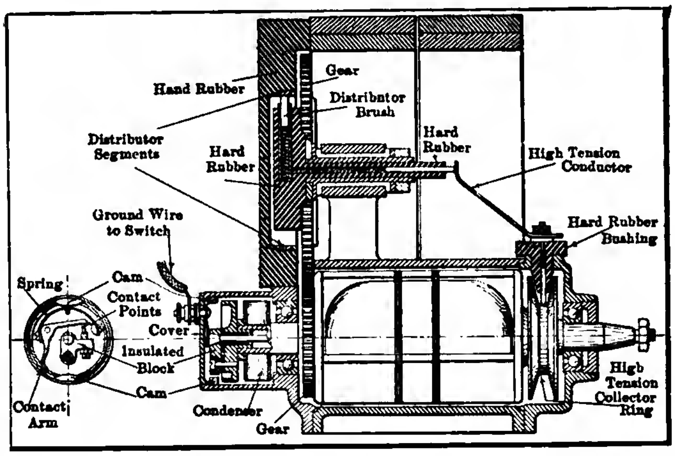

Fig. 4—Section of a high-tension form of magneto with connections in conformity with accepted practice

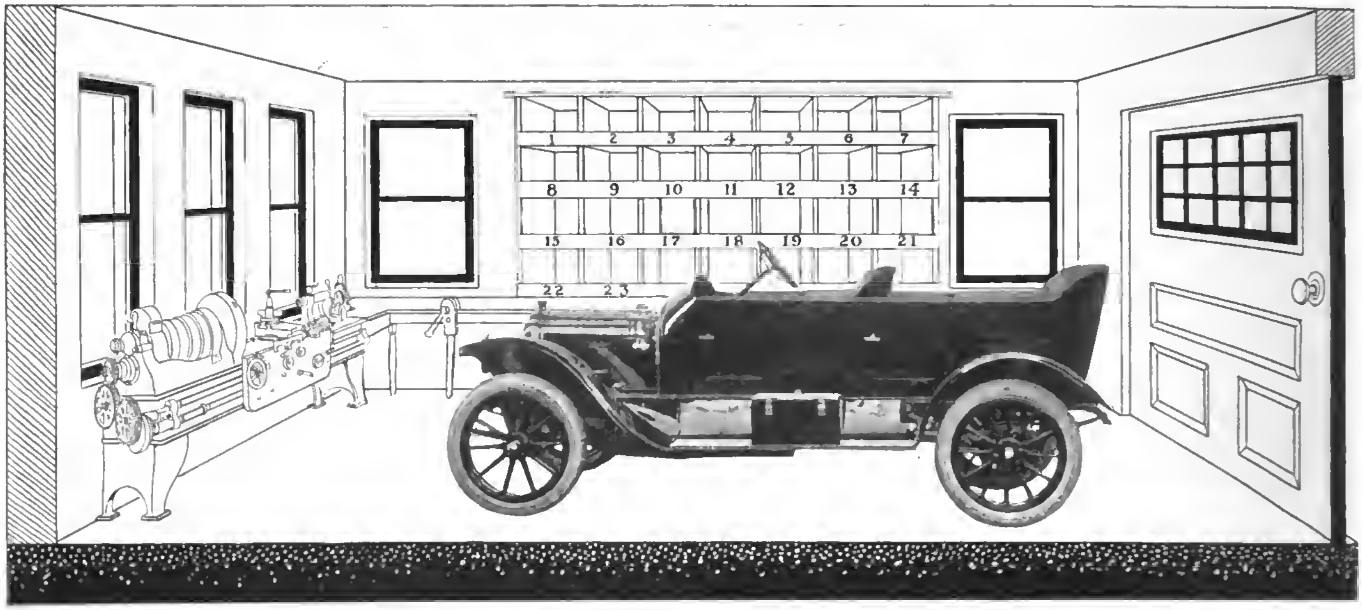

Fig. 1—Length of garage in proportion to the length of the automobile, indicating facilities accompanying ample space

Important Construction Details of Garages

ROOM is desirable for reasons entirely outside of the lighting consideration, and Fig. 1 is offered as a fair illustration of the conditions which should obtain in a private garage. This figure shows the length of the garage in comparison with the length of the car as about in the ratio of 2 to 1. It is impossible to expect to be able to keep a car in good working order if it is so cramped for want of space that work cannot be done upon it excepting under conditions which retard effort, and defeat the use of proper tools.

With sufficient space, good lighting, and certain tools, it is possible to maintain a car in good working order at small cost. There are many little things which happen in the everyday effort of running an automobile that will lead to a large outlay if they are not given the attention they deserve. It will not be necessary at this time to enumerate the tool equipment which might be advantageously employed even in a single-car garage, but it should be remembered that enough space ought to be afforded when the building is planned, so that a lathe and a drill press may be added at any time. In this example (Fig. 1) the lathe is shown at the end opposite the entrance, and since the building is in section, it will be fair to assume that there would be ample room for a drill press and a light forge in the portion of the space not here given. The same illustration presents evidences of a work bench, and what is equally to the point, a shelving system with numbered pockets, so that the parts which might be carried in stock may be kept therein, and a record may be made of the pockets in which the parts are stored, so that when the occasion requires they may be found without much trouble. Leaving the question of the tool equipment as one to be dealt with separately, this illustration will suffice for the intended purpose, but it may not be sufficient to convince the new owner of the fact that he will need more room than that occupied by the car. The usual way is to build the garage first and thereafter discover that room is at a premium.

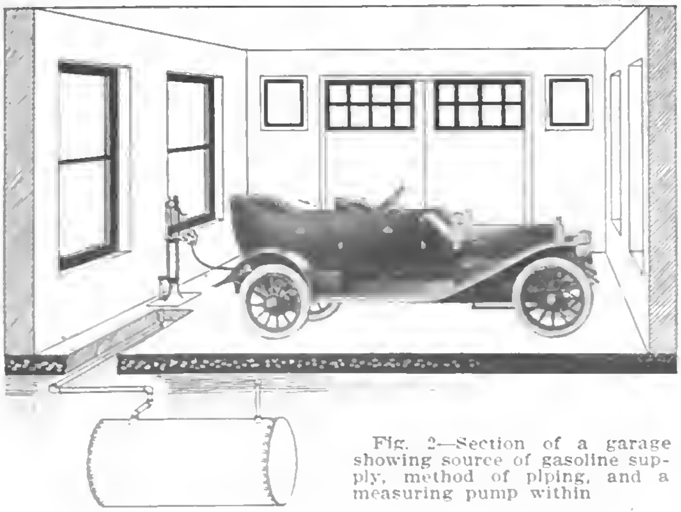

Fig. 2—Section of a garage showing source of gasoline supply, method of piping, and a measuring pump within

Gasoline Should Be Purchased in Quantity and Stored

The fuel problem in the isolated private garage is a particularly difficult one to handle; it would seem not at all difficult to ring up the nearby store at any time and order 10 gallons of gasoline; the boy ought to bring it around in a few minutes The trouble with this plan lies in the fact that he will not be there on Sunday morning, and the gasoline problem will become a serious one. It may take two or three hours to find a place, and so much time wasted on a fine morning when one desires to go for a ride, seems much longer.

If it may be taken for granted that the hand-to-mouth method of obtaining gasoline is not a good one on the ground that it has its decided uncertainties, even so, the Board of Fire Underwriters will object to the presence of more than 10 gallons of gasoline in a garage, unless provision is made for its proper storage. It will also be remembered that the cost increases substantially 50 per cent. when the fuel is purchased in 10-gallon packages, instead of by the barrel: then too, it is a better grade of fuel as a rule which comes in the original barrel.

Fig. 2 is offered as an indication of the customary manner of disposing of the fuel problem, in which a galvanized steel fuel tank is buried outside of the building line of the garage, and a supply pipe is led from the tank to a measuring pump, which may be placed at any convenient point within the building proper, with the understanding, however, that the pump should be free from leaks, so that gasoline will not be spilled about, or it should be placed in a suitably contrived fireproof closet with proper means of ventilation. All these details, in any event, will best be cared for by consulting the rules and regulations of the Board of Fire Underwriters having jurisdiction, and it will

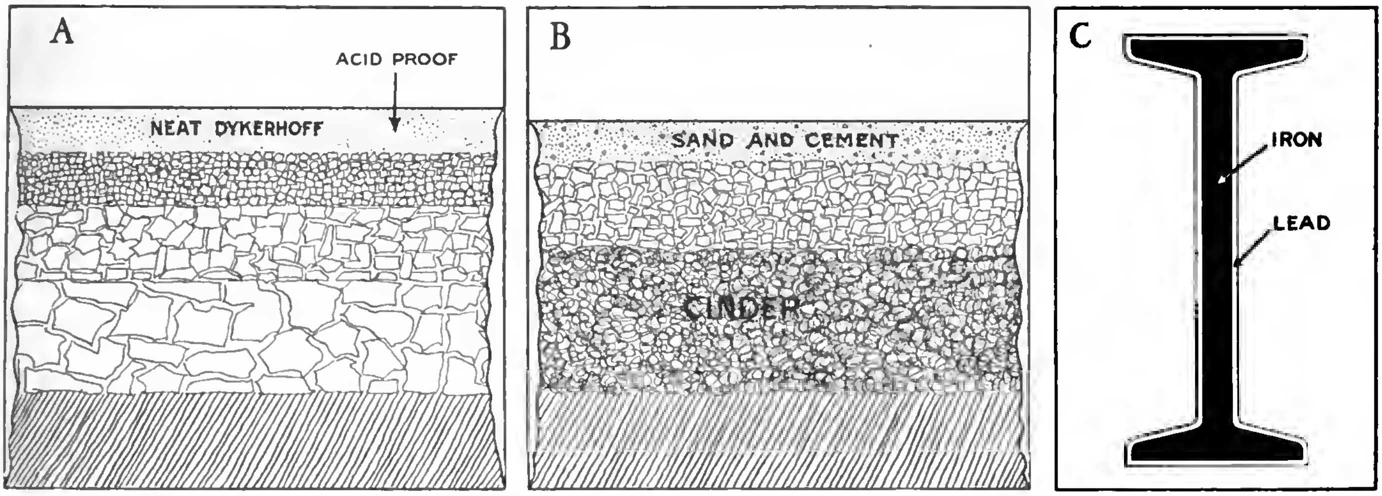

Fig. 3—A presents an acid proof cement floor employing neat Dykerhoff cement for the top layer, and broken granite with Dykerhoff cement beneath. B, cement floor using ordinary cement on a cinder bed when gasoline automobiles are stored. C, lead sheathing over iron work to render it acid proof in an electrical garage

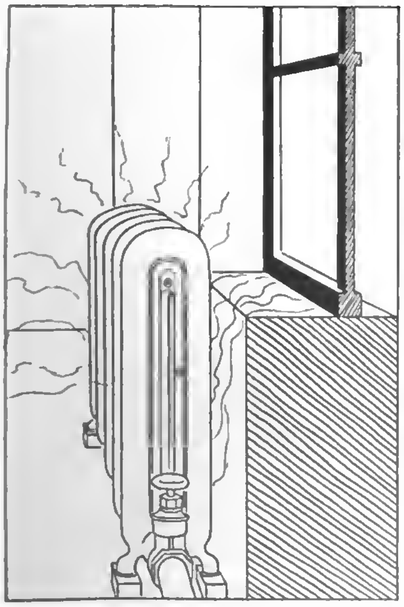
be well to remember that the respective Boards in the several districts do not always agree as to the efficiency of a plan. Money will be saved by consulting the rules and regulations of the Board first, and making the plans in the light of information which may be so obtained.

Cement Floors Are Sources of Possible Annoyance

If a small garage is designed for gasoline automobiles only, the cement floor may be composed of (a) a cinder bed, possibly 6 inches deep; (b) a grout of broken stone, 7 to 1 cement with sand filler, for about 3 inches, topped off by sharp sand cement in the ratio of 1 of cement to 2 of sand, worked to a neat condition for the surface. Such a floor will afford the desired solidity, and will last for a very long time because the oil and other accumulations from a gasoline automobile will work no ill effect. Should the garage be devoted to the storage of an electric automobile, if the battery is of the lead-lead genera, and provided it is to be charged by means of a suitable equipment attached to the garage, there is an excellent opportunity to induce a relatively high depreciation of the floor, in view of the fact that the sulphuric acid electrolyte used in the battery will attack ordinary grades of cement, and if this condition goes on sufficiently, the floor will be destroyed.



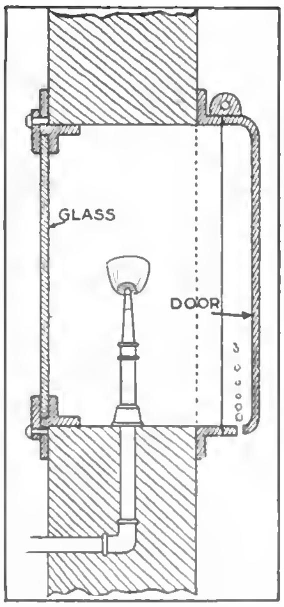


Fig. 4—Steam heating radiator placed adjacent to the window, so that the cold air is heated as it enters. Fig. 5—Lighting pocket located in the wall with a tight glass bull's-eye separating source of light from the gasoline contaminated air within the storage space

To get around trouble of this sort, the plan as indicated in Fig. 3, may be accepted. In this plan, the lower strata is broken granite, coarse at the bottom, and tapered off to sizes which will pass through a one-inch mesh, the whole occupying a depth of say 4 inches. The next layer is made up of broken granite in sizes which will pass a 3-4-inch mesh and is grouted down, using Dykerhoff cement in fine granite screenings for the layer next to the top to a depth of possibly 2 inches, and finally neat Dykerhoff cement to a depth of three-quarters of an inch for the top coat. Fig. 3 shows how iron work may be protected from the corroding effect of acid and its fumes which come from charging the battery; the plan comprises sheathing over the iron work with thin sheet lead. In a small establishment this sort of thing should not be necessary; iron work may be avoided.

If the building is well ventilated the question of the acid action on the surrounding metal will be lessened in any case, but it is necessary to settle a matter of this sort when the structure is being planned.

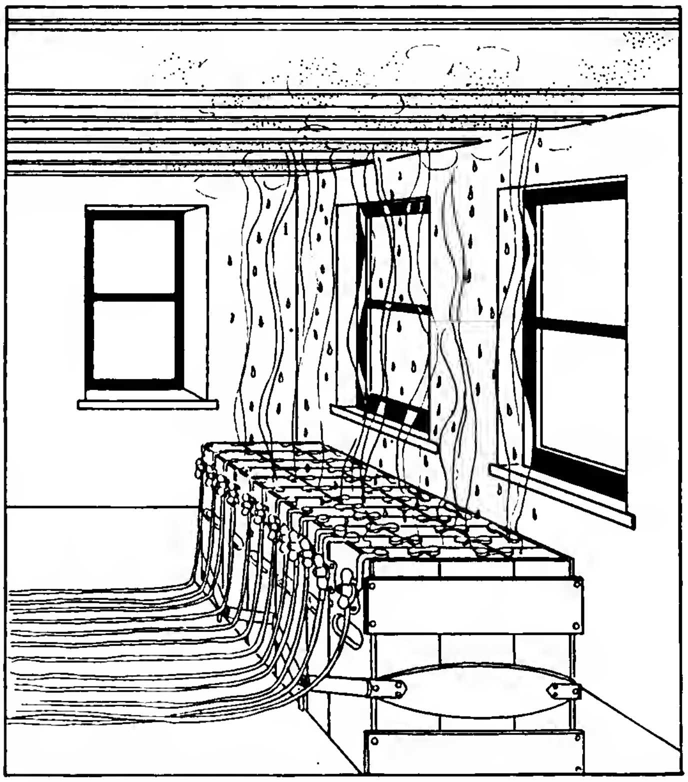

Fig. 6—Shows a storage battery on charge, and the acid fumes given off as the battery nears its complete state of charge, which fumes are corrosive

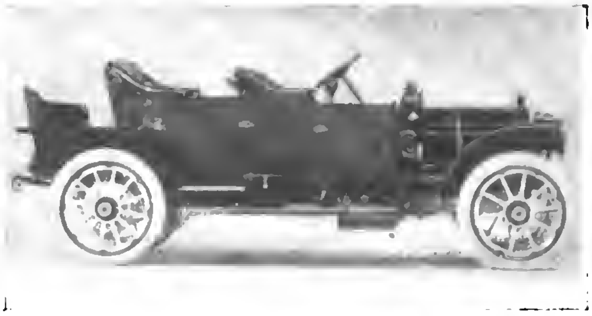
Packard Nineteen

THIS year the new models are being presented a little early, due, perhaps to the briskness of the automobile trade, but quality must be reflected in this same story, on the count that if the automobiles were not good, to sell them would be a relatively difficult matter. At all events the Packard line for 1911 is here and the Packard Motor Car Company, of Detroit, Mich., offers the statement, with its data of the cars, to the effect that the newer body work is a departure from former practice in important particulars, among which the new fore-door style of body is accentuated. Then, it is pointed out that the painting colors are different; Packard blue and cream yellow vies with Packard gray, and a Packard method is also given prominent mention by the company.

The new open cars, instead of having bodies of the "torpedo" type, are made with both the front and rear body panels in strong relief and with victoria carriage lines. These panels are painted Packard blue, striped with Packard gray. The frame, bonnet, fenders and similar parts are black, while the wheels and running gear are Packard gray, striped with black.

Packard from the Mechanical Point of View

The mechanical improvements in the 1911 cars are extensive



but are all in the nature of detail refinement, developing previous models. The "Thirty" line and prices are as follows:

Touring car, phaeton or with close-coupled body, in standard finish and equipment, including Packard extension cape cart top, $4,200.

Runabout, in standard finish and equipment, including runabout top, $4,200.

Touring car with leather victoria top, in standard finish and equipment, $4,450.

Phaeton with leather victoria top, in standard finish and equipment, $4,415.

Touring car with full glass canopy top, in standard finish and equipment, $4,645.

Limousine, in standard finish and equipment, $5,450.

Landaulet, in standard finish and equipment, $5,550.

Fore-door limousine, in standard finish and equipment, $5,650.

Fore-door landaulet, in standard finish and equipment, $5,750.

Coupé, in standard finish and equipment, $4,900.

Packard "Eighteen" offers the following choices:

Open car or with close-coupled body, in standard finish and equipment, including a five-ton extension cape cart top, $3,200.

Runabout, in standard finish and equipment, including runabout top, $3,200.

Open car with leather victoria top, in standard finish and equipment, $3,415.

Limousine, in standard finish and equipment, $4,400.

Landaulet, in standard finish and equipment, $4,500.

Fore-door limousine, in standard finish and equipment, $4,600.

Fore-door landaulet, in standard finish and equipment, $4,700.

Coupé, in standard finish and equipment, $3,900.

General Specifications of the Cars

Motor.—Four vertical, water-cooled cylinders, "Thirty," bore, 5 inches; stroke, 5½ inches; 30 brake horsepower at 650 revolutions per minute. The "Eighteen" bore, 4 1/16 inches; stroke, 5⅛ inches; 18 brake horsepower at 650 revolutions per minute.

Wheel base in the "Thirty" standard chassis is 123½ inches; runabout, 108 inches. The "Eighteen" standard chassis is 112 inches; runabout, 102 inches. Tread, 56½ inches.

The "Thirty" tire equipment is, front and rear, 36 by 4½ inches. For the "Eighteen," front and rear, 34 by 4 inches. Continental demountable rims. Flexible bead clincher tires of any of several standard makes.

The painting situation is represented as follows:

Open cars.—Body and door panels, Packard blue, striped with Packard gray. Under-body, bonnet, radiator, frame, fenders, splashers, battery and tool boxes and moldings, black. Wheels, axles, springs and other running gear parts below the frame, Packard gray, striped with black.

Enclosed Cars.—Body lower and door panels, Packard blue, striped with Packard gray. Upper-body, under-body, bonnet, radiator, frame, fenders, splashers, battery and tool boxes and moldings, black. Wheels, axles, springs and other running gear parts below the frame, black, striped with Packard gray.

In trimming the automobilist has the following choices:

Open cars.—Seats, black, hand-buffed, straight-grain leather, tufted. Running boards and front floor and heel boards, cork carpet. Fiber mat in tonneau.

Enclosed bodies.—Front seats, black, hand-buffed, straight-grain leather, untufted. Front floor and heel boards, cork carpet.

Top—Inside Driven Brougham, on Eighteen Chassis
Middle—Thirty Touring Car with Seven Passenger Body
Bottom—Thirty, Front Door Runabout Body and Chauffeur's Seat

Hundred and Eleven

Rear compartment, below the belt, blue goatskin, tufted; roof and quarters, blue broadcloth, untufted; floor, blue carpet to match.

Standard Car Equipment Furnished

Extension cape cart top, with side curtains, corner light curtains, storm front and envelope on all open cars except runabouts, the equipment of which includes runabout top, with corner light curtains, storm front and envelope. Storm front omitted when corner light curtains are fitted to windshield. Two gas headlights and gas tank, two oil side lamps and oil rear lamp, horn, complete set of tools, with tire repair and rim changing equipment, one extra demountable rim, irons for two extra tires, one-ton jack.

Enclosed body equipment consists of dome light, with switch and battery, toilet cases to match upholstery, push button and buzzer, speaking tube, folding foot rail, hat and parcel carrier, coat hook, adjustable ventilators, morocco-covered robe rail and two umbrella holders in "Thirty" bodies. This equipment is unusually complete even for a car of this type.

The Motor Details

Cylinders are cast in pairs, with integral water jackets and valve chambers. Cylinders and pistons are ground and interchangeable. Pistons are fitted with four rings, ground top, bottom and sides. Cylinders, pistons and rings are lapped together after assembling. Castings for cylinders, pistons, etc., made in the Packard foundries from especially imported gray iron.

Crankshaft has three large main bearings, supported by massive webs. Connecting rods are drop-forged.

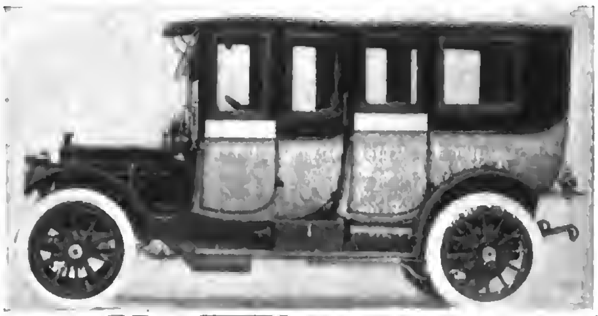
Quiet running is obtained by great rigidity and accuracy in manufacturing and inspection. All bearing surfaces are ground. Bushings are all carefully fitted.

Valves are all mechanically operated and interchangeable. Positively lubricated camshafts are enclosed within crankcase. Inlet and exhaust valves are on opposite sides of the cylinder pairs. Camshaft, magneto and water pump gears are positively lubricated and protected from dirt, being contained in a separate but integrally cast, oil-tight extension of the crankcase. The latter, it will be remembered, is cast in two halves, split horizontally on the center line.

Crankcase has three horizontal sections. Uppermost section is supported by main frame and forms engine base. Crankshaft bearings are held between the uppermost and middle sections. Bottom section is an oil well, easily removable for inspection or adjustment of connecting rods, camshafts and other inside parts without disturbing crankshaft bearings.

Entire crankcase is cast of special aluminum alloy in the Packard foundries. All motor parts are protected by integral web enclosing space between motor and frame. Crankcase is divided into front and rear compartments by a central partition supporting the center crankshaft bearing.

Carburetor is of the firm's own design and manufacture, combining float feed, automatic mixture regulation for all motor speeds and uniform temperature. Primary air intake may be shut off to assist starting in cold weather. It has a water-jacketed cylindrical mixing chamber. Auxiliary air inlet is automatically regulated for varying speed by a spring-controlled poppet valve. Small lever on dashboard governs the poppet-valve spring tension to suit different atmospheric conditions.



Top—Front Door Limousine Is a New Departure for Packard
Middle—Front Door Landaulet Has a Distinctive Appearance
Bottom—Touring Car with Torpedo Body Looks Natty and Neat

Butterfly throttle is above aspirating nozzle in mixing chambers.

Gasoline supply is by gravity from a copper tank under the front seat, with a three-way gasoline valve which controls the main supply. There is, also, a 5-gallon reserve and shut-off. The capacity of the standard "Thirty" tank, including reserve supply which is contained within main tank, is 21 gallons. Capacity of the "Eighteen" tank is 18 gallons. In runabouts, phæton and close-coupled cars, gasoline feed is by pressure, there being an automatic pump on the engine and also a hand pump for emergency.

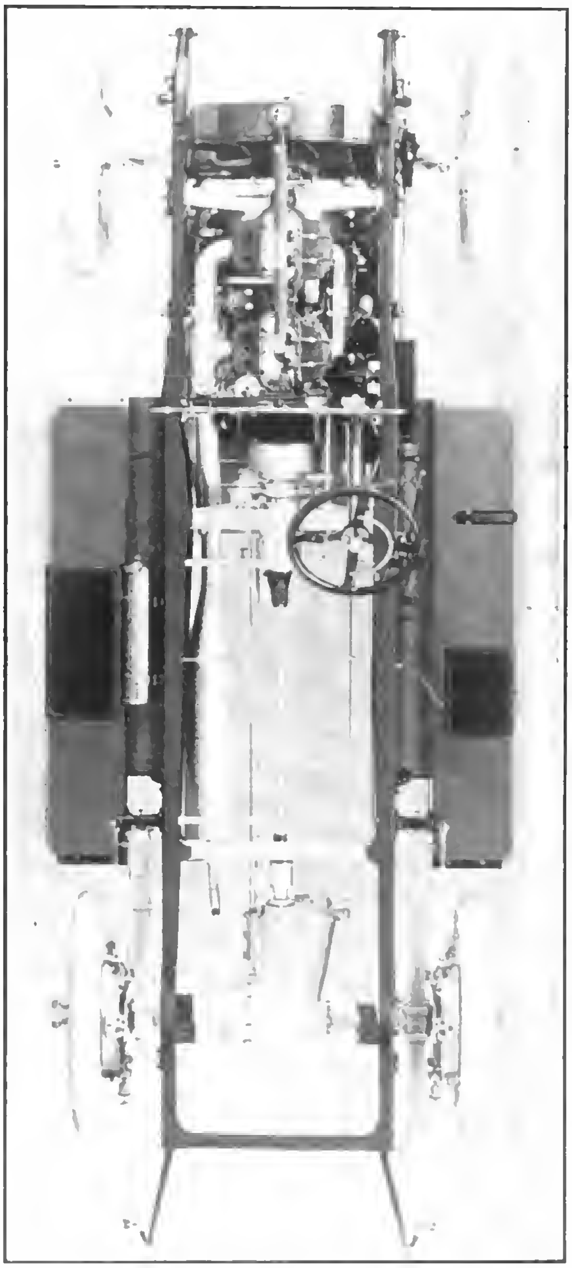
Ignition is the jump spark by special system, current supplied by Eisemann low-tension magneto with storage battery for starting and reserve. Transformer coil for magneto current and vibrator coil for battery current are located in unit box on dashboard. Coils and primary circuits are independent but secondary circuits and spark plugs are common to both systems. Magneto is placed on the left side of the motor bed and is driven by enclosed gears. Storage battery is in a box on the running board. Convenient hand and "kick" switch, combined with a Yale lock, is placed between battery and magneto coils. Commutator for the battery primary current is on a vertical shaft at the rear of the motor and is driven from the exhaust valve camshaft by enclosed bevel gears. Primary wiring from battery to coil is carried through protecting tube. Secondary wiring from magneto distributor to universally-jointed knife switches at spark plugs is also satisfactorily carried through a copper pipe.

Lubrication has a number of features, motor being oiled by splash from crankcase to cylinders and all motor bearings. Positive supply of oil flowing independently to front and rear compartments of crank-case by means of a double plunger pump. Oil feed is easily regulated, pump strokes being adjustable. The pump is accessibly located at left of motor and is driven by a worm on the exhaust valve camshaft. An oil reservoir placed between the pairs of cylinders—this location insuring uniform temperature and fluid—gives easily flowing oil, even in cold weather. The capacity of the "Thirty" oil tank is one gallon; "Eighteen," 2½ quarts. Two drip sight-feeds are placed on the dashboard. Anti-clogging devices on crankcase drain cocks and stops to prevent their accidental opening. Transmission and differential are run in oil. All universal joints are encased and packed with grease. Other running and wearing parts are provided with grease cups or oil holes.

Methods of Motor Control

Motor speed is regulated by hand lever on steering wheel and by foot pedal, both acting directly on throttle. Hydraulic governor to steady the motor running and compensate for varying loads within the limits of volitional throttle setting. The pedal provides means of instantaneous acceleration as well as continued high-speed running. The governor is incorporated in the water circulation system, being part of the pump unit. The ignition spark is advanced or retarded for most efficient ignition under every running condition by a small lever on the steering wheel.

Starting crank has an automatic latch which holds starting crank in upright position when not in use. There is a compression relief handle near starting crank.



"Thirty" Chassis from Above

Motor cooling is by positive water circulation through cellular radiator and motor cylinder water jackets by gear-driven centrifugal pump. A noncaking filler cap is placed on the radiator water tank. A suction strainer on water pump is easily removable for cleaning without breaking any water connections. Belt-driven, ball-bearing fan is provided with an adjustment for belt tension. Capacity of water circulation system in Packard "Thirty" is 5 gallons; in "Eighteen," 4½ gallons.

Unit Principle of Speed Changing Used

Clutch is of the dry plate type, engaging gradually with delicate positive action at all times. Casing plates are faced with special friction material. The shaft plates are of metal.

Unit principle of speed changing is used with the final drive and differential gears contained in rigid rear axle unit. This method has as its advantages few parts, light weight, high efficiency. No transmission elements are on main frame and no intermediate parts require alignment between the clutch and rear axle. A long propeller shaft having minimum angularity is used with effectively encased universal joints at each end.

Speed changing gives three forward speeds and reverse, providing most efficient gear ratios for all kinds of driving, obtained by simple arrangement of sliding gears. Third speed forward is direct drive. Gear shifting lever has selective action in single quadrant.

This lever moves forward and backward for forward speeds, and laterally into a notch for reverse. Reverse movement is locked by thumb latch. Gear shifting is assisted by spring locks on the shifter shaft, which determine correct engagement of gears. Gear shifting toggles and other actuating parts are enclosed in gear housing and protected from dirt. Annular ball bearings are used throughout transmission.

Aluminum housing that contains speed changing gears, final drive bevel gears and differential is internally ribbed for strength and rigidity.

Housing provided with oil plugs and inspection holes. Differential gear unit supported by its own bearings, rear axle sections being removable without disturbing gears. Rear axle and final drive and differential gears run on annular ball bearings. Ball end thrust bearings

There are four brakes, all acting directly on rear-wheel brake drums, thus obviating braking strain on transmission.

Service brakes are external contracting bands, operated by pedal. Emergency brakes are internal expanding segments, operated by hand lever. Internal brakes enclosed and protected by drum disks. Bayonet locks on internal brakes to prevent rattle. All brake operating systems are equalized through toggle levers, with operating pull on one end and direct connection to the brake levers on the other. This results in an even pull on both brakes, which serves to prevent skidding of the car on many occasions, particularly on wet days.

Running Gear and Chassis

Main frame is a channel section, pressed steel frame, arched above the rear axle to allow liberal spring action in connection with the desirably low body. Top and bottom flanges of side bars have integral gussets for the reception of cross bars, simplifying the construction and increasing the strength.

Steering is by means of a worm and sector steering gear with large hand wheel, entirely wood covered, including spokes near the rim, for comfort.

Worm and sector are forged integrally with their respective shafts. Large, rigid steering column. Heavy drop-forged jaw type yokes on front axle and forged steering knuckle spindles. Ball thrust bearings in steering knuckles. Steering connecting rod ball and socket joints encased. All steering gear bearings and connections directly lubricated by grease cups. Steering connecting rod is above front axle, being in position to minimize transmission of vibration to driver's hands.

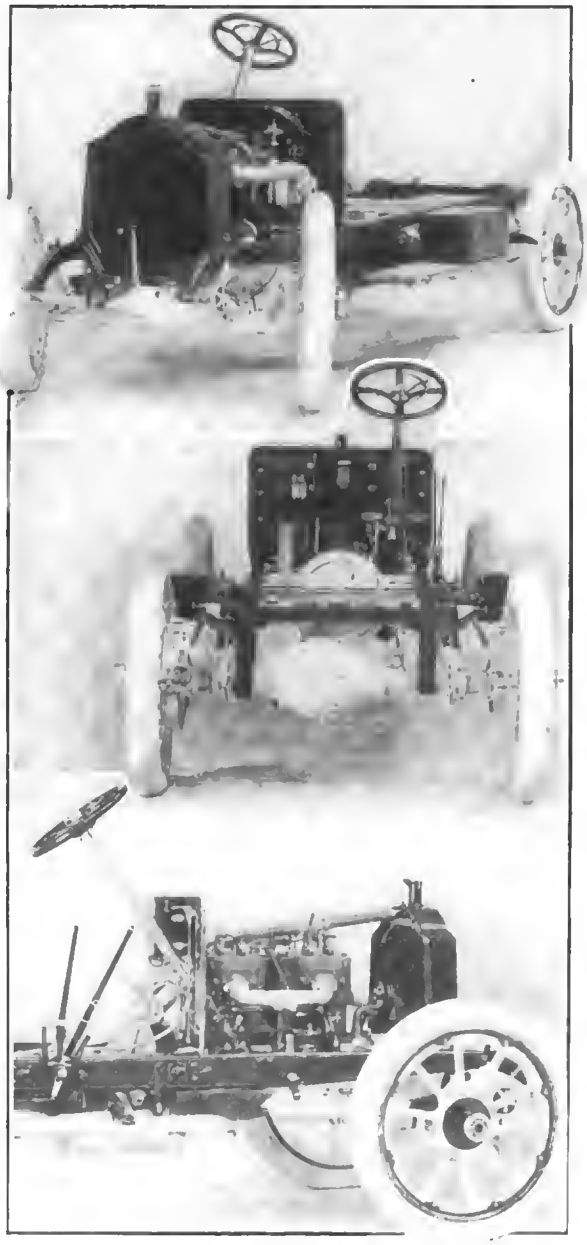
Four wide, semi-elliptical springs carry the load. Rear springs are 56 inches long in the "Thirty," and 50 inches long in "Eighteen." Front springs are 40 inches long in both. Compression grease cups lubricate all spring shackle bearings. Shock absorbers are placed on both front and rear axles.

Front axle and stationary sleeves of rear axle are of steel tubing of large diameter and heavy gauge. Rear axle tubes are pressed into and riveted within flanged collars bolted to the aluminum differential gear housing. Roller bearings in front wheels.

Body construction is of sheet aluminum panels over wood framework. Bonnet is of aluminum and secured against rattling. Fenders, aluminum, flanged for rigidity. Splash aprons between front fenders and car. Rear fenders so attached to body as to be practically water-tight. Splash aprons between frame and running boards.

On this and the opposite pages are shown a plan view of the chassis, and front, rear, and side views as well. From these some idea of the construction of the car may be gained by anyone, whether familiar with Packard construction or not. In this connection, the brakes just mentioned, for instance, will be found to be practically the same as last year, at which time attention was called to the fact that all brakes were located on the rear hubs, thus avoiding any pull of the gears ahead of this, or any braking through the transmission, as it entailed by the use of a shaft brake.

So, too, with the steering gear, this was brought out last year for the first time with grease cups to supply the internal lubrication, which practice is now continued, a year's usage having developed no defects in it. Speaking of the steering gear, the spindles and jawtype yokes are drop forged. The connecting rod, between the knuckles and the steering column, is placed above the front axle in a manner which minimizes stresses, vibrations, and consequent jar on the driver's hands.



Front, Rear and Sides of Chassis

Last year, when the dry-disc clutch was brought out for the first time, there was, perhaps, a slight doubt as to whether this was the perfect form of clutch for Packard cars, but after a season, it is again announced as the type to be utilized, proving that the move was in the right direction. This clutch is described as of the dry-disc type, that is, it is a disc or plate clutch so designed as to run perfectly without lubrication, the absence of the latter giving it the designation, dry. This clutch affords the desirable feature of gradual engagement, and, as it operates without lubrication of any kind, provides the same action in cold as in warm weather. By the use of a special lining material, the clutch will not burn.

Effective Lubrication

Lubrication is a decidedly interesting subject, if for no other reason than from the fact that delicate machinery can not be run, at least not successfully, without some form of lubrication. In this copious lubrication is far better than a scanty supply, so the decision to use the combined pump and splash system is a wise one, for this double system has the merit of supplying not only continuous flow of oil to all bearings, but to the fact that it is also an economical one, the same oil being filtered and used over and over again. As to details, the splash lubrication system is the same simple, positive system formerly used. A double plunger oil pump feeds the front and rear compartments of the crankcase, in which are independent oil levels. The oil pump strokes being adjustable, the oil feed is easily regulated. The pump is accessibly located at the left of the motor and is driven by a worm on the exhaust valve camshaft. Oil is taken from a vertical copper reservoir close to and between the pairs of cylinders, this location insuring uniform temperature and fluid, easily-flowing oil, even in the coldest weather. The capacity of the oil tank of the "Thirty" is one gallon. There are two drip sight feeds on the dashboard.

Model L Cartercar, Made by the Cartercar Company, Pontiac, Mich., in Both Side and Front Views

SPECIFICATIONS OF THE CARTERCAR, CARTERCAR COMPANY, PONTIAC, MICH.

Motor, four vertical cylinders.
Bore, 4¼-inch.
Stroke, 4½-inch.
Cylinders, pairs, and offset.
Valves, all on right side.
Finish, all engine parts ground.
Power, 30-35-horsepower.
Cooling, by centrifugal pump, direct-driven.
Radiator, flat tube.
Lubrication, combined pump and splash.
Ignition, dual jump spark, magneto and batteries.
Transmission, Carter patented friction drive.
Final drive, single chain in oil.
Frame, pressed steel, of channel section.
Springs, semi-elliptic, 52-inch rear, 46-inch front.
Wheelbase, 110 inches.
Tread, standard
Axles, front tubular, rear live.
Wheels, twelve spoke artillery.
Tires, 34 by 4 quick detachable.
Brakes, internal expanding hub brakes and friction reverse.
Steering, irreversible worm and sector.
Steering wheel, 16-inch, with spark and throttle levers.
Body, straight line design.
Colors, three options—Brewster green, Cartercar red, or combination.
Upholstery, black leather, dull finish.
Equipment, magneto, two gas lamps, generator, horn, mats, complete set tools, jack, tire repair outfit, etc.
Price, $1,600 f. o. b. Pontiac.

FRICTION driving being the central idea about which the Cartercar is constructed, it will be well to give that part of the whole chassis greater prominence. Since this replaces both the transmission and clutch of the ordinary case, it will at least be fair to devote as much space to it as would ordinarily be given to those two very important parts of the automobile mechanisms.

This drive and the name of the car are both due to Byron J. Carter, now dead, but who, in 1901, designed and built the first friction-driven car. This progenitor of the modern and up-to-date Cartercar was still in use up to two years ago, in Ann Arbor, Mich., when the company purchased it for exhibition purposes. So well and wisely did Carter construct his first vehicle that the cars to-day show little variation from the original design, aside from the natural progress which the industry as a whole has showed in the nine years, and smaller refinements added to make it a more comfortable and better looking machine.

Two models are made and sold to-day, known by the trade names of Model L and Model H. Barring such slight differences in the chassis as the larger size of one motor makes, the two are identical, one being made to sell at $1,150, while the higher powered Model L sells at $1,600. For this reason only the larger model will be described in detail.

The motor of this machine is of the usual four-cylinder type, water-cooled, with cylinders cast in pairs. The cylinders are of the L-head type, with all valves on one side, this being the right-hand side of the machine. The cylinders are cast from a close-grained run of gray iron, and are first roughed out in the lathe, seasoned, then ground to size, using micrometer gauges. Pistons, too, are of gray iron, and ground to size, both top, bottom and sides. The bore is 4¼ inches, and the stroke 4½ inches, resulting in a power output of 30-35. The valves used are of the best quality steel, with electrically welded heads, a form which experience has proven very successful. The three-bearing crankshaft is of a selected grade of open-hearth steel, machined and ground to size, the pins being very carefully ground after hardening. Rigid specifications in the drop-forging process insure a good class of material and fair workmanship in this very important part of the engine. In assembling much pains is taken with the camshaft and crankshaft location and alignment, special jigs being used for this purpose. The crankshaft bearings are plain, but of fine material, which, aided by the careful assembling process, results in a very low loss through internal friction.

Following the assembling, the work is proven true by a long run-in test, after which the motor is inspected. It is then, after passing inspection, tested out on the test-block, when the actual power delivered is measured. The final result is a motor of ample power, high and very low speeds, and one that runs quietly and well at all times, and answers the throttle readily. Lastly, the engine is thoroughly tested out when the whole car has been assembled and is ready for the road, the engine doing the bulk of the work on this tryout.

As to disposition of the accessories, it will be noted in the cuts of the engine on the opposite page that the inlet pipe is led downward from the ports in the cylinders, thus giving it a very simple and symmetrical form, while at the same time making it unusually accessible. The exhaust pipe, on the other hand, is carried up above the ports, this also resulting in simplification. Since heat is disastrous to magnetos and other forms of ignition apparatus, the magneto is located on the opposite side of the engine to the valves and pipes. It is driven from the gear compartment in front, through a side shaft, which also drives the water pump, the latter in fact being forward of the magneto. The former as well as the latter may be disconnected at will and taken out, without disturbing the other parts. This desirable result is accomplished through the medium of universal couplings in the driving shaft, which permit the taking out or replacement of either one of these accessories.

Cooling is made effective, regardless of the heat encountered by this pump, which is of the centrifugal type, gear-driven, as just described, very liberal water-jackets on the engine, a large flat tube, cellular type of radiator, with a fan as an auxiliary. The radiators are of the first grade of flat copper tubes, designed to present the greatest surface to the cooling action of the air, which action is assisted by the rapidly revolving fan located just back of the radiator, and belt-driven off of the crankshaft. An eccentric hanging provides a means of taking up any slack of the belt, which change is effected through the loosening of a single bolt, making the change, and tightening the bolt again.

Crankcase is cast in two parts, an upper and a lower. The upper carries the crankshaft bearings, as well as the supporting arms and the pads for the various accessories, while the lower acts as an oil reservoir and dust extruder. The lubrication system is a combination of the splash and the forced circulating methods. For the splash system, the lower half of the crankcase is kept half filled with oil, in which the connecting rods dip on each revolution, at the lowest point in the cycle, thus splashing the oil around the inside of the motor in the form of a mist, which lubricates everything therein very thoroughly. This oil level is a fixed one, and is maintained by the oil-circulating pump, which is gear-driven off of the camshaft.

Ignition is by dual systems, a low-tension magneto, previously spoken of, which furnishes current to a single, non-vibrating dashboard coil, the voltage being raised there to a sufficient amount to bridge the usual spark gaps, the final spark being of the jump variety. In addition to this jump-spark magneto system, an auxiliary battery is carried in a battery box on the running board, this working through the same dashboard coil, and a timer carried on the rear end of the camshaft.

A carbureter of the central float type is carried low down on the valve side of the engine, the low position assuring the use of every drop of fuel available, and insuring positive fuel feed on steep hills. This carbureter, like the other components of the car, is very simple, being made with a single setting, which makes the device self-adjusting after setting.

Coming next to the friction drive, which makes for higher power at the road wheels, simpler control, fewer parts, and easier operation, there is a driver, so called, which transmits the power of the engine to the friction disc, from which the drive is by means of a chain enclosed and running in oil, back to the rear axle. This transmission driver consists of a cross member keyed rigidly to the forward end of the disc shaft, and to which are secured two flat tempered steel plates, the opposite ends of which are bolted to the flywheel itself. The rotation of the flywheel exerts a straight pull on these plates, thus rotating the disc, and at the same time the disc and shaft are free to slide forward and back along the disc shaft, thus allowing the changes in the speed of the car, differing positions giving different speed ratios. It will readily be seen that the disc shaft is by this means made an integral part of the crankshaft, in so far as rotary motion is concerned, although the two happen to be made for manufacturing convenience in separate parts, and entirely independent as to forward and backward movement.

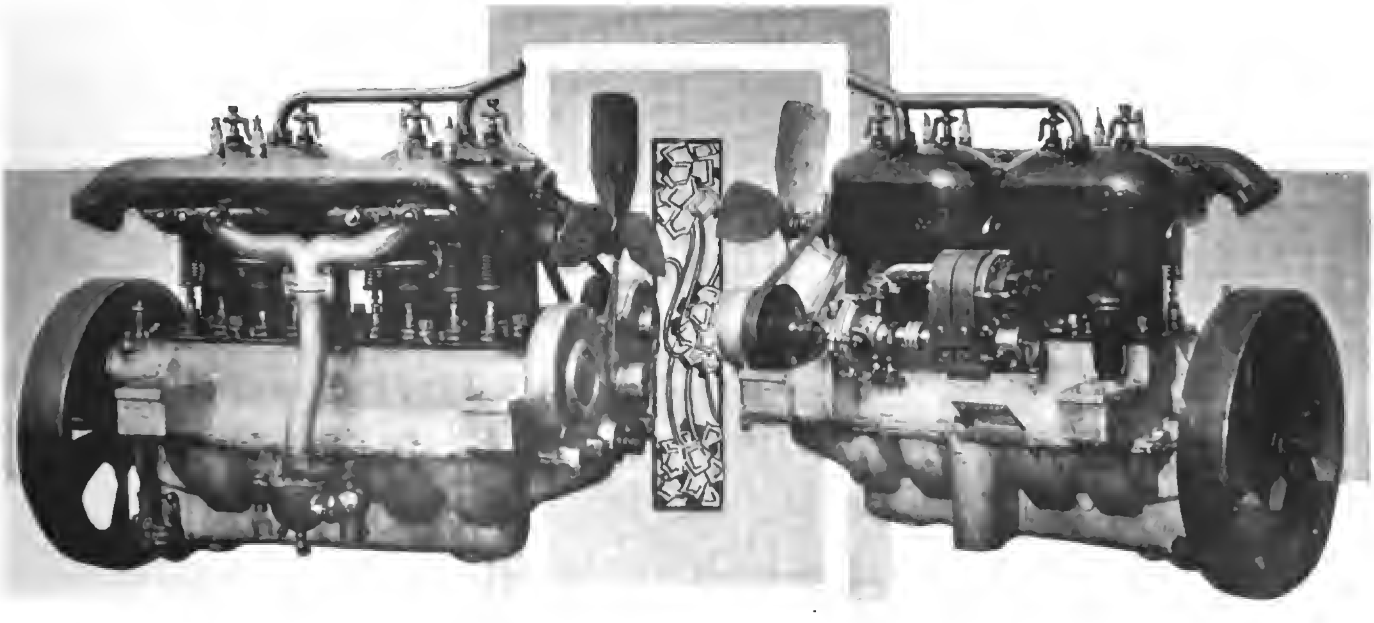
To reduce the frictional losses to an absolute minimum, the transmission shafts are mounted upon high-duty ball bearings of large size, great strength, and thus, high capacity.

The thrust bearing of the disc shaft is carried in a hanger immediately in front of the disc, and is of the four-point type, with balls of large size. This bearing is of special design and construction, and the ball races are of the finest tool steel, accurately machined, hardened and ground to micrometer gauge true to a half thousandth of an inch. This four-point type of bearing is the nearest possible approach to entire absence of fraction, owing to the fact that the periphery of the balls' travel is always exactly perpendicular to their axes of rotation, and thus there is no tendency to jam.

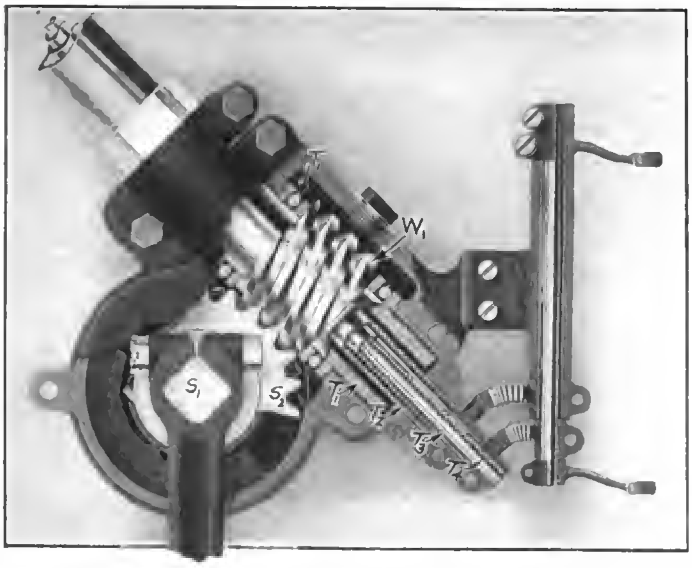
To return to the transmission considered as a whole, that is, from the viewpoint of the man who is about to buy one, the friction transmission is of the simplest possible construction, has the fewest number of moving parts, and is the most economical to maintain and the easiest to care for. It consists of a special alloy disc on the terminal of a shaft connected with the flywheel. Against this disc a sliding friction wheel with a fiber rim is engaged at any point on the surface from the center to the outside, thus giving any speed desired. Sprockets and chain connect this countershaft with the rear axle.

Speed changes are made by means of a hand lever, this one lever determining all speed ratios from low to high; also the reverse. After the lever has been placed in the desired position, control is then obtained by means of the left pedal which engages the friction, thus corresponding in action to a clutch as commonly used on other automobiles.

The control afforded by this transmission is one of its chief features, and its great superiority over other forms of trans-



Valve Side of 30-35 Horsepower Engine of Model L Cartercar Accessory Side, Showing Magneto and Pump, Also Fan



Section Showing Construction of Carter Steering Gear

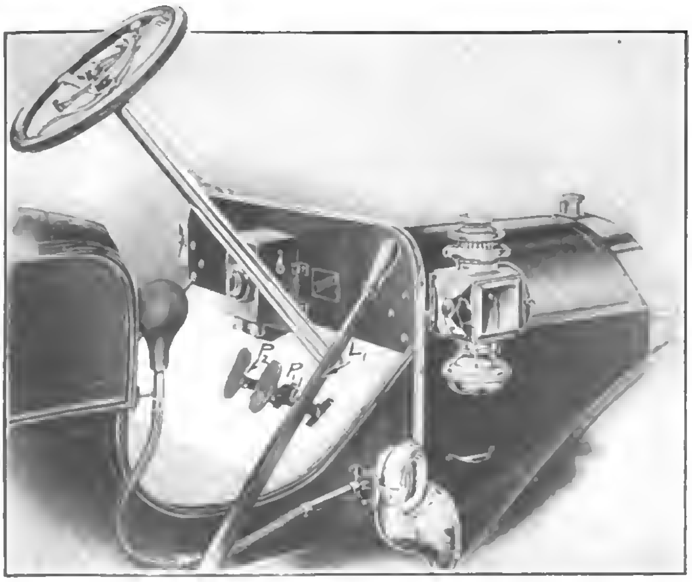
mission is instantly apparent. Any number of speeds is provided from zero up to the maximum, and changes can be made instantaneously without noise.

The car is started or stopped by the use of this friction pedal with the left foot, in conjunction with a powerful brake, operated by the right foot through a similar pedal. It will be seen that the operator has instant control of the car at all times without the necessity of reaching for hand levers, or of removing the hands from the steering wheel.

The fiber rim or filler on the friction wheel can easily be renewed after it has become worn down. The car will run upwards of 4,000 miles before the filler needs replacing.

The moving parts of this transmission are lubricated by turning three grease cups occasionally, an operation which can be performed by a lady or gentleman without soiling the clothes.

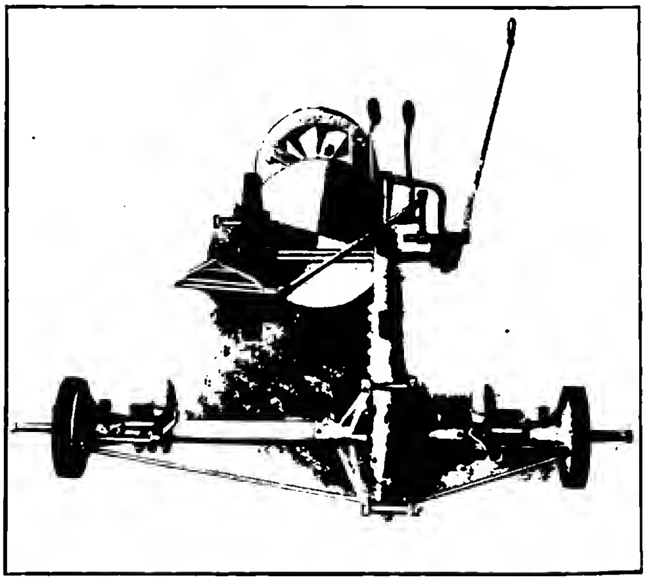
Simplicity of control always appeals to the man about to purchase a new car, for he has visions of the ten or more things to be done at once, all of the things to be thought of, all of the parts, levers, etc., to be operated, and anything that sounds like a reduction in the number of parts, a lessening of the things to be cared for or done, and a reduction in the worry incident to the whole, sounds very advantageous. Thus, with the friction transmission, while operating the car through crowded streets, or on thoroughfares where frequent slowing and stopping are necessary, control can be had entirely with the feet, acting in connection with the throttle and spark levers on top of the steering column. There is no need for changing speeds as in other cars, for the extreme flexibility of the friction permits the car to be run as slowly as need be on the high, and with no danger of jerking the car or of stalling the engine.



Friction Drive Makes a Very Simple Control System

It is a well-known fact that there is a great waste of power on low and intermediate speeds in a gear transmission: also that the meshing and turning of a number of gears produce considerable noise. The Cartercar friction transmission is noiseless on all speeds, and has a very high efficiency, delivering more power to the rear wheels than any competitive form of transmission. This has been proven, in part, by the great success of this particular form of transmission in this make of car in hill climbing contests and private trials of the same nature, in which the car is said to have ascended grades of 50 per cent, that is a rise of 50 ft. in 100 ft. length.

Referring specifically to the cut of the transmission as a whole shown on this page, the parts may be noted in their correct positions, relative to one another. Referring also to the steering gear drawing at the head of the page, this will be seen to be of the worm and segmental gear type. The worm W_1 meshes with the segment S_2 which carries on the end of a squared



Detailed View of Whole Driving System, Both Friction and Chain

shaft S_1 the operating lever, which is connected to the front axle, and through which the actual work of steering is done. This squared shaft is made an integral part of the worm segment, and the necessary strength of this combination is thus gained. The thrust from worms is known to be considerable, and in this case, proper provision is made for it, by fitting the two ball thrust bearings, T_1 on each side of the worm. Steering is actually effected by the movements of the external tube T_1, upon which the worm is fixed. Within this, there is another tube T_2, which forms a bearing for the lower end of the larger-sized tube, while within this in turn is a third tube T_3 which operates the throttle lever. This Chinese nest of tubes carries still further, the final inner one T_4 carrying the movement of the fingers on the steering wheel down to the spark lever, operating the timing disc on the magneto and timer.

At the bottom of the page is shown a photograph of the dash board, front seat, and control mechanisms, revealing clearly the small number of parts necessary to complete operation. The hand lever L_1 operates the changes of speed, the two foot pedals corresponding to the usual clutch and brakes, one, the right, P_1 operating the internal expanding foot brakes, while the other, the left, P_2 throws the friction disc out of engagement so that changes of speed may be effected.

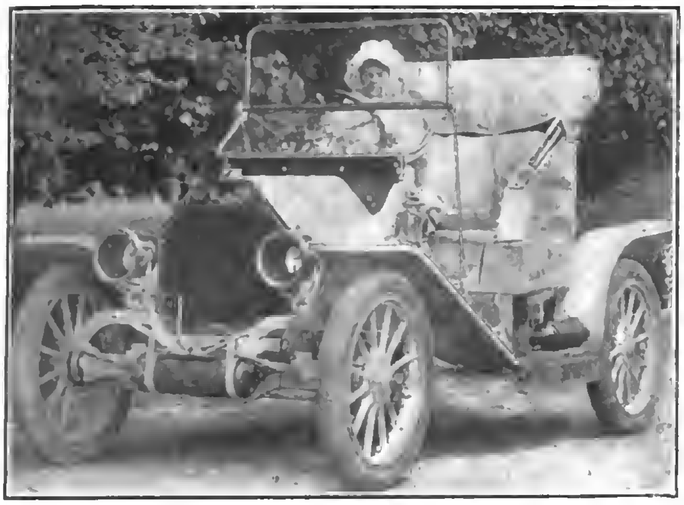


Fig. 1—Willys-Overland Model 38 equipped for a trip to the coast with a woman pilot

Characteristics of Model 38 Overland

THIS model of the Willys-Overland cars is the one which is being used in the "transcontinental" run. The start was made from New York for the Pacific on May 23, and, while it is not the idea of the projectors of the trip to do any speeaing at all, the fact remains that the automobile will be tested out to the limit of its touring capabilities, and it will also have to sustain its reputation for ease of operation in the hands of a woman driver. As reported last week, Miss Blanche Scott has the matter of the piloting of the automobile in hand.

Some Features of the Model 38 Overland

Ground clearance is a necessity in any automobile which is expected to serve under touring conditions, especially in a transcontinental tour, and in this model, the low point, which is at the center of the rear axle, is as shown in Fig. 2. This photograph was taken by the "staff photographer" of the AUTOMOBILE, in New York, before the car started on its run to the Pacific, and, in the photograph, to show the exact clearance, a rule was placed vertically at a point just behind the rear axle; this rule tells the story; the clearance is 10¾ inches at the lowest point, and, as designs go, this clearance is quite up to the most fitting requirement.

The I-section front axle is shown in Fig. 3 just at the knuckle, and the Elliott type of knucke is also clearly brought out. A further examination of the construction discloses a tight construction around the hub flanging F, with a packing joint P to exclude all foreign substances and retain grease. The knuckle K is a substantial drop forging, heat treated to bring out the desired kinetic qualities, and the bearing surfaces B1 and B2 are not only ample but the fitting is well executed. The knuckle-pin is locked by means of a nut which is castellated, and a grease cup G at the upper end serves to supply lubricant to the bearings. The wood of the wheel is second growth hickory of the first grade; bastard spokes are cast out, and the whole construction is such as to lend confidence to the user.

Rear Axle Is Designed to Withstand Service

Considering Fig. 2, which shows the rear axle very plainly, all that will be necessary for the time is to present Fig. 4 which is another view of the axle, taken at a point to bring out the construction of the axle and brakes with details of construction at this point. It has been the aim in taking these photographs to let the camera tell the story, and it is so well indicated that no further statement will be made at this time, unless to point out that the brakes are of large area and of proven worth; they will, of course, be given a good working test in this run.

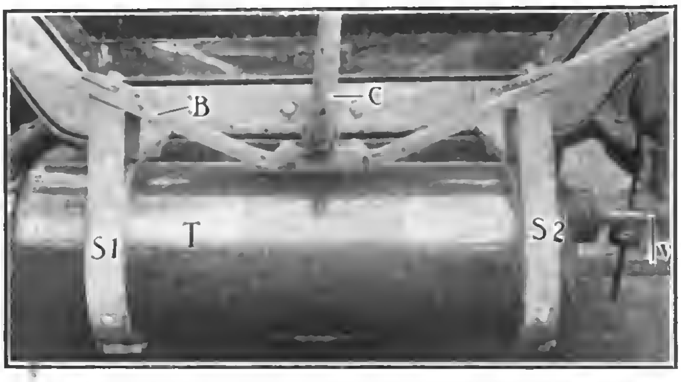

Fig. 5—Front view presenting method of holding the acetylene tank in a position which clears the starting crank

Special Disposition of the Lighting Equipment

Referring to Fig. 5, of the placing of the lighting tank T, the support B is so made and placed that the tank is below the starting crank C, and the tank is held in secure relation by the bands S1 and S2. This idea has the virtue of having the tank close to the lamps which receive the gas, (acetylene) and the

HARTFORD, CONNECTICUT, one of the first cities in the United States to take up the manufacture of the automobile, occupies a leading position in motordom. It has several big factories devoted to the production of automobiles and the Automobile Club of Hartford is one of the typical motor organizations of the country.

The importance of the automobile as a factor in the commercial life of the city and State is as well appreciated in Hartford as it is anywhere in the country and this appreciation is largely accountable for the work done by the automobile club.

It has overcome prejudice and modified hostility on the part of lawmakers by a nice observance of the rights of the public and, as a result, the use of the automobile and the rights of motorists are conceded by the public.

Connecticut has one of the most liberal automobile codes in the land. There is no law that says that a certain maximum speed shall be deemed *prima facie* evidence of recklessness and on the other hand, the motorists agreed in exchange for this reasonable provision, that the roads of the State shall never be used for racing.

This statute was urged by the State association, but the chief factor in that body always has been the Automobile Club of Hartford. The club is large, reckoned from any basis, having nearly 400 members. It is intensely active and has a hand in everything affecting motoring.

But its great mission is toward the sporting end of automobiling. Its annual reliability contest is one of the classics. It always attracts a representative entry list and it is conducted upon precise and technical lines so that when a car shows excellence in the contest, the excellence of the car itself is a long way on the road toward proven worth.

This year the big event, the All-Connecticut Reliability Contest, is scheduled to start May 19 and after covering about 80 per cent of the State, will finish May 21. The route is some 600 miles long. Rules of the A. A. A. will be strictly followed and will be administered by officials who have had much experience in that line of work. Chairman Butler of the A. A. A. Contest Board is an honorary officer of the run.

There will be seven classes under the rules as provided in the divisions of Class "A" and cups for the winners in each class have been offered.

Former runs of the club have proved successful to a notable degree and the entries this year foreshadow an unusually favorable contest.

The sporting history of the club includes a hill-climb in 1907 and endurance runs in 1908 and 1909, all of which were milestones in the record of automobile development.

In addition to the annual contest, the club engineers numerous runs during the season, of one day duration. These are mostly for club members and have proved to be an enjoyable feature of club life. This year the club is preparing a more comprehensive program and at least one tour of two days will be made, while half a dozen of the shorter and more informal events will be carded.

The contest this year will be held under the auspices of the Hartford club, but in conjunction with that organization, the clubs of Bridgeport, New Haven, Willimantic, Litchfield County, New Britain and Yale University will act co-ordinately and support the event in every way possible.

The Connecticut Automobile Association devotes itself largely to legislative problems and so the individual clubs are obliged to direct their activity toward other ends, so that the whole field may be adequately covered. Thus the matter of good roads is left largely in the hands of the various organizations about the state. The Hartford club, because of its central position and size and importance, is a leader in this particular. It also makes a specialty of defending its members who are subjected to persecution rather than prosecution for alleged infringements of the laws. While the State statute does not provide any specific speed limit, beyond which it is presumed that the motorist is not observing reasonable caution, nevertheless, there was formerly a pronounced disposition upon the part of certain peace officers to make it disagreeable for tourists. When arrests are made under unwarranted circumstances, the club takes up the battle of the individual and in every legal way tries to get justice for the alleged offender.

Within the membership of this organizaton has been formed the Aero Club of Hartford, and many of the most influential motorists have joined the enterprise. Instruction in the principles of aviation is a feature of their meetings and in the near future, a meet which will bring together several of the leading air navigators is being planned.

The Automobile Club was formed in 1904 with about fifty members. Like almost all of the senior automobile organizations of the country, it led a precarious sort of life for several years, but commencing in 1907, when it began to take part in the big sporting events of motordom, the club started to grow mightily. Its membership swelled to nearly 300 and quarters were taken in Allyn House. During the ensuing two years, more progress was recorded and the club leased a storeroom adjoining the hotel property and fitted it up as headquarters.

As power, influence and finances were piled up, the needs of further equipment became apparent and this Spring it was determined to secure a country house for the benefit of the members. After a careful search for available locations, the members have decided that the place shown in the accompanying illustration fills every requirement. The house is a large, old-fashioned country place, standing in a fine estate in the hills back of Hartford, just a comfortable distance from the city to afford a pleasant run. A restaurant, grill-room, sleeping quarters, and all other accommodations of a first-class country club will be installed as soon as a few formalities have been completed. It is intended to open the new house early this season.

The social life of the club is extensive and entertainments are frequently given. It is a distinct factor in the progress of Hartford and is highly regarded by motordom throughout the country.

The officers of the club always have been representative citizens. Hiram P. Maxim, son of Sir Hiram Maxim and one of the most advanced thinkers in mechanical lines, has served several times in executive posts. At present Mr. Maxim is chairman of the Contest Committee of the club and is a leader in the Aero Club of Hartford.

C. H. Gillette, who was identified with the first running of the Vanderbilt Cup race, is president. Mr. Gillette served as referee at the opening Daytona speed meet and was secretary of the A. A. A. for a period. A. G. Hinkley is vice-president. Mr. Hinkley is one of the leading automobilists of Connecticut and is an enthusiast on the subject of the future of the motor car. Philip E. Curtiss, a newspaper man, connected with the editorial staff of the Hartford Times, is secretary and C. D. Alton, Jr., is treasurer.

Messrs. Gillette and Curtiss also serve respectively as president and secretary of the Connecticut Automobile Association. W. T. Plimpton, with the title of assistant secretary, is in direct charge of the detail work of the organization.

The club is one of those solid bodies, founded upon a principle and seeing a definite object to attain. It is a sort of rallying point for motordom, and if it has a pre-eminent characteristic it is that of sturdiness and quiet strength.

Aviation Meet for Louisville

LOUISVILLE, May 16.—An aviation meet will be held at Churchill Downs, on Saturday and Sunday, June 18 and 19. Col. J. L. Gribble will manage the affair and in addition to the aeroplane flights there will be a series of automobile races, open to local drivers only. These races will be run for handsome loving cups and will comprise not only events for speed at various distances, but also trials for car control and other tests of driving skill, while special events for women drivers also will be arranged.

Glenn H. Curtiss, Charles F. Williard, "Bud" Mars, Horace B. Wilde and Carl Bates will bring their air craft to Louisville and take part in the events.

Names Atlantic City as Its Goal

At a recent meeting of the board of directors of the Binghampton Automobile Club it was decided to hold the annual run of the club from Binghamton to Atlantic City. The event will take place some time in June.

Coming Events in the Automobiling World

June 20-July 6...Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.

Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 13-25, 1911..Chicago, Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill Climbs, Etc.

May 18-19........Norristown, Pa., Third Annual Endurance Run, Norristown to Scranton and Return.

May 19-21........Hartford, Conn., All-Connecticut Reliability Contest.

May 21-22........Bay Ridge, L. I., Club's Endurance Contest Around Long Island, Crescent Athletic Club and Long Island Automobile Club.

May 21-22........Track Race Meet, Memphis, Tenn., Homer C. George, Manager.

May 27, 28-30.....Indianapolis, Ind., Automobile Races, including Championship Events on Motor Speedway.

May 28...........White Plains, N. Y., Hill Climb under auspices of Amateur Automobile Contest Association.

May 30...........Fairfield, Conn., Hill Climb under auspices of the Bridgeport Automobile Dealer's Association.

May 30...........Oklahoma City, Okla., Reliability run under auspices of the "Daily Oklahoman."

May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill, Automobile Club of Bridgeport.

June 2...........New York City, N. Y., Trade Association, Orphans' Day Excursion to Coney Island and Return.

June 4...........Worcester, Mass., Fourth Annual Hill-Climb, Dead Horse Hill.

June 6-14........Atlanta, Ga., Reliability Run to New York City, New York Herald and Atlanta Journal.

June 7...........New Haven, Conn., Hill-Climb up Shingle Hill, Yale University Automobile Club.

June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.

June 11..........Baltimore Hill-Climb of Automobile Club of Maryland.

June 14-15.......New York, Reliability Run of Motor Contest Association.

June 15..........Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, Through the Southwest.

June 16-22.......Albany Automobile Club, Albany, N. Y., Sixth Annual Tour to Atlantic City and Return.

June 25..........Port Jefferson, Long Island, N. Y., Hill Climbing Contest, Automobile Club of Port Jefferson.

July 4...........Indianapolis, Ind., Cobe Trophy Race. Held on Speedway Track, Chicago Automobile Club.

July 4...........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

July 18-22.......Milwaukee, Reliability Run, Wisconsin State Automobile Association.

July 30..........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

Aug. 3-5.........Galveston, Tex., Beach Races, Galveston Automobile Club.

Sept. 5..........Wildwood, Pa., Speedway, Labor Day Race Meet of North Wildwood A. C.

Sept. 17.........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.

Sept.............Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

Oct. 1...........Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.

Oct. 8...........Philadelphia, Fairmount Park Race, Quaker City Motor Club.

Oct. 15..........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 25...........“The American Cup,” Argentina, Sociedad Sportiva Argentina, near Buenos Ayres.

May 28-June 9....St. Petersburg, Russia, Automobile Exhibition.

May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.

June 2-8.........Prince Henry (German) Touring Competition.

June 13-18.......Scotland, Scottish Reliability Trials.

June 20..........French Voiturette Race.

June 21..........French Stock-Car Race.

June 22-July 5...Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.

June 27..........Speed Trials at Kiev, Russia.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

IF it is true that there will be upwards of 200,000 autoists added to the stream this year, a large number of them will have a garage problem to tackle, and of this number many will decide that they will put a private garage in their own back yard. It looks easy enough to do so if space affords, but a year's experience in an undertaking such as this will be sufficient to tell them in language which will equal the threadbare plainness of the Anglo-Saxon tongue that there is more in the problem than the mere housing of a car. There are many indications of the fact that it is better to pay $25 per month to the keeper of a public garage than to take advantage of the apparent utility of a private establishment, only to come home with the automobile off of a muddy road, roll it into the garage, and let the accumulations of the roadside form a crust over its delicately tinted surfaces. When the crust comes off next day the delicacy of the tint will take wings. The cost of service in a private garage plan must include the cost of refinishing the car, if, in the absence of a chauffeur, the owner says "manana" (to-morrow) everything will be made spick and span—to-morrow never comes.

⁂

GASOLINE, while it is as safe as any fuel can be, is the storehouse of energy in compacted form, and must be treated accordingly. It is not a safe procedure to construct a pit under an automobile in a garage and have the same so tightly made that it will serve as a pocket for accumulations of gasoline and air in proper proportion to make an explosive mixture. There was a time when it seemed to be necessary to crawl under automobiles to fix them, or better yet, to make an examination with a view to ascertaining why they would not run; as they are now made, referring to those which are worth having, it is not necessary to explore the under region, and a pit, if it is made at all, will be for one purpose only, i. e. to court an explosion.

⁂

BRIGHTON BEACH furnished a new version of the attitude of the autoing public in respect to racing; patronage was so profuse that the authorities in charge of the race were short on its welcome. At one time between seven and eight o'clock in the evening of the first night there were 750 automobiles, full of autoists who were anxious to pay the entrance fee and see the sights. The back yard of the race track was packed with automobiles; they came from near and afar, and there was never a moment during the whole time when they showed much of the impatience which they, by right, might have allowed to come to the surface, due to the lack of preparedness of the management of the event. The real answer to all of this lies in the fact that the weather was cold and the wind blew; the attendance on former occasions was moderate, and it was thought, perhaps, that there might be a comfortable attendance, but there was no inkling of the jam that followed. This opening track event, if it spells anything at all, rather goes to show that the autoing public is ready to support the industry, either in or out of school.

⁂

GLIDDENITES, now that the Pathfinder is home from its long jaunt, are gladdened with the joyful news; it tells of the extent of good roads, both in fact and in prospect; they are not so bad as some might have supposed, and of the attitude of the citizens of the Southwest, it is enough to say that they extended their accustomed welcome—the whole-hearted kind, penetrating in its characteristics, and lasting besides. There is a surprise awaiting the citizen who thinks that the States which are included in the path of the Glidden Tour are lacking in automobile interests. It has been shown elsewhere in this issue of THE AUTOMOBILE that the industry is well represented both in manufacturing and from a trade point of view; moreover, the number of automobiles now being used in these States are in full keeping with the general condition of the automobile trade in other parts of the country. It is claimed that the Glidden Tour will serve as a missionary band this year, and it will.

⁂

ARE automobiles now so well made and so simple that any woman can take one and run it without having to call upon a man to assist in cranking, or in doing any of the work that may have to be attended to in order to obtain the expected service on the road? This year an attempt will be made to prove that any properly designed automobile is up to this requirement, and even though the proof may be a little lacking in some respects, the fact remains that it will show great contrast considering the automobiles of even a few years ago; they even refused to bow to the wiles of a man of mechanical experience.

How Independents Will Fight A.L.A.M.

PLANS of the Association of Motor Car Manufacturers, the organization of independent makers formed in Detroit recently, are outlined with considerable detail in the following letter addressed to various independent automobile companies by Henry C. Walters, attorney for the association:

"Referring to the meeting of automobile manufacturers held on the 2d instant, pursuant to the call sent out by me at the request of the organization committee under date of April 25th: The meeting was held and was largely attended, as you will see from the notations on the side of this sheet. As no word was had from your company, I think it is not amiss to advise you in some detail of what was done, especially as the final meeting will be held at the Hotel Ponchartrain, Detroit, at 10.30 a. m., on Monday, the 16th instant. It is hoped that you will have a representative present authorized to act in the matter of joining the organization.

"I think it advisable to state to you that this association of companies has not been brought about through the efforts of a Mr. Russell, who has been sending out circulars from Indianapolis, announcing meetings which were not held. This statement is made for the purpose merely of conveying the information, and with all due respect to Mr. Russell. A number of inquiries as to his connection or non-connection have been made, and it is thought that you, too, may be interested.

"If the reason you are holding back from joining a defensive organization is because you have private assurances that you will not be disturbed, you may find something to interest you in the information which I now give you, that many of the companies against whom actions are now pending had applications for licenses before the association, which had not been acted upon, and which it seemed, from the inquiries made by the association, would be favorably disposed of; some of the other companies that have been sued were privately informed by those high up in authority in the A. L. A. M. that no action would be commenced against them.

"I learned these facts through personal conversation with officers of the companies now engaged in defending themselves against the actions instituted. My opinion is that the licensed association has its plan laid and knows now just what companies suits will be started against, and just what ones will not be molested. I do not think the fact of joining the association will result in the commencement of suits against the particular ones joining—even if their names are made known. I cannot do better, by way of informing you what has been done on the 2d instant, than to send you the following extract from one of the letters which I sent out on the 3d instant.

An association was formed to be known as the Association of Motor Car Manufacturers. The association is for the purpose, as expressed in the articles of agreement to be signed by each member, of the development and advancement of the automobile industry, the stimulation of legitimate competition, improvement of motor car construction by voluntary interchange of economic ideas relating thereto, and the mutual protection of its membership against illegal and oppressive action. Any person or corporation manufacturing motor cars, pleasure or commercial, and not operating under a license issued by the claimed owner or owners of the Selden Patent, is eligible to membership in the organization; the applications of those desiring to come in at a later period will be passed upon by the executive committee, if it is decided to admit others later. There seems to be a well defined opinion that those who stand aloof at this critical period in the automobile industry, so far as non-licensed companies are concerned, should not be taken in afterwards. I am not prepared to say what will be the ultimate decision in this regard. The affairs of the association will be managed by an executive committee of five persons, which committee will be elected or appointed by a general governing body composed of one member or trustee or representative from each manufacturer in the association. The membership or affiliation fee is $500. The annual dues will be not less than one-fifth of one per cent of the retail list price, nor more than one-half of one per cent, of the total number of cars manufactured and sold during the current year; the dues are to be called in by the executive committee as the necessities of the association seem to require. Some difficulty was encountered in the matter of fixing amounts to be paid in by the members of the organization, for the reason that it is not known just how much will be needed. The initial object of the association is that of defending against present and future actions instituted by the A. L. A. M. It was thought that a number of the best patent lawyers and two or three equity lawyers should be retained by the organization; they will need the assistance of mechanical experts of the highest type; this, together with the taking of testimony on behalf of the complainants and the defendants, about the country, will be rather expensive. A wholehearted, instead of a half-hearted, defence must be made of every action commenced, and the penny wise and pound foolish method must be relegated to the rear. These considerations resulted in the fixing of the minimum and the maximum—the understanding being, of course, that only such monies will be called for by the governing committee as are actually needed. The governing committee will have power to increase the annual dues by a majority vote. Twenty-two companies were represented at the meeting, some companies having several representatives and almost all the companies having more than one representative present. A number of letters were received explaining the absence of representation and expressing willingness to join the organization. Almost all the companies represented actually signed, or agreed to sign the articles of agreement; some of those present stated that they had to take the subject up with their boards of directors before signing, but each of such persons said that they had no doubt at all but that their boards would take favorable action. The meeting was adjourned until Monday the 16th instant, at 10.30 a.m., second floor of the Hotel Ponchartrain, Detroit, Mich., at which time it is expected that one duly accredited trustee or representative will be present from each company in the organization; more than one person may come and may take part in the meeting, though each company will have but one vote. The principal object of this meeting is the election of the executive committee. I have given you a full résumé of the articles of agreement, to the end that you may present the matter to your board for its consideration. If you decide to join the association wire me at once to that effect, and I will call upon you with the original agreement for your signature. It was definitely decided not to send out over the country copies of the agreement nor to publish names of the membership. It will undoubtedly interest you to know that if Judge Hough of the Second Circuit sitting at New York declines to suspend the operation of the injunction, in the Ford case, pending the appeal the A. L. A. M. will likely file a batch of additional suits and apply for preliminary injunctions based on the action of Judge Hough. His action will not be binding on Circuit Judges in other circuits, but it will have a strong persuasive effect on account of the comity existing between the different circuits. It can be urged with great force, in support of these applications, that a long and expensive trial has been had, with many eminent counsel engaged on both sides, and that since the patent has been sustained by Judge Hough so strong a presumption exists in favor of its validity that preliminary injunctions should issue forthwith. The present outlook is that a decree in the Ford case will be entered the latter part of this month or early in June; upon the entering of that decree, the question of the suspension or non-suspension of that injunction will at once arise. If you will be so kind as to let me hear from you at the earliest possible date, I will see that the original agreement is turned over to you for signature, if you wish to join us. The letter gives the entire substance of the agreement, with the exception of the preamble, which merely sets forth the reasons for the formation of the association. The present members of the association hope that your company will affiliate with them. Number of companies represented at meeting of May 2nd—22. Number of companies unable to send representatives but expressing by letter their willingness to join—10. Number of companies declining to join—1. Number of companies invited to attend on May 2nd——68.

DETROIT, MICH., May 18.—A special representative of THE AUTOMOBILE called upon Henry E. Walters, who is the spirit in the move which is being made to organize the independent makers of automobiles, and, while it is admitted that the organization is now about completed, Mr. Walters declined to state particulars in relation to the same. The regular correspondent of THE AUTOMOBILE, in a special wire in relation to the same matter, wired in as follows: "Organization of Association of Motor Car Manufacturers perfected here Monday and officers elected. Headquarters to be in Detroit. Henry C. Walters, attorney and spokesman, will give no further information."

Rain Mars Denver Race Meet

DENVER, May 18.—Track records were shattered during the two-day meet held here Friday and Saturday, and despite various kinds of weather, the races were a success. In the five-mile race for cars valued at $1250 and less an Overland defeated a Warren-Detroit in 6.20.

The five-mile handicap was won by the Darracq (Kerscher) from scratch in 5:11:80, as was also the Free-For-All handicap for the Governor Shafroth cup, three miles in 3 minutes flat. In this contest the Overland (Ballit) was second and the Warren-Detroit (Hough) was third.

The Benz (Oldfield) in the mile time trials made 54.1 the first day of the meet and reduced the mark to 53.80 yesterday. The Darracq (Kerscher) made the mile in 57.

Vogue of the Automobile in the South

MEASURED by the space of only two years, a revolution, or rather an evolution, of road conditions in the South has occurred. The good highways of that section of the land on a basis of two years ago must be multiplied by ten to reach a figure anything like the present status.

Of course, the whole evolutionary movement is based upon the constantly growing use of the automobile. In fact, the South has adopted the motor car as its own and the vogue of the automobile has swept through Dixie like a prairie fire on the Nebraska steppes.

For instance out of Jackson, Tenn., a town of about 20,000, there are 14 of the finest stone roads the hand of man can produce—most of them of considerable length. Rome, Ga., is the center of a spider line web of improved roads and so insistent are the residents of this county that these roads shall be continued that they recently formed a delegation to wait upon the citizens and officials of a procrastinating neighboring county and protest against their neglect to improve the highways.

Up in the famous Blue Grass country, around Davidson County, Tenn., the roads look like asphalt pavements, newly laid.

At this time in Brownsville, Tennesseeans from all over the State are gathering for the purpose of providing ways and means for the pushing of this good road movement as it never before has been forced.

In Atlanta the work of one man tells more than aught else, that is, the work of Major John S. Cohen, editor of the Atlanta *Journal* and father of the Atlanta-New York tours.

Major Cohen is following up this great work of road building in the hope that within a few years he will see the materialization of the dream of his life—a fine highway from New York to Atlanta.

This, then, is the prime motive of the New York-Atlanta tour. It is a good roads tour and it is having a wonderful effect upon the citizens of the country adjacent to the route of the tour as laid out last year. Even to-day it is conceded to be the best 1,000 miles of continuous roadway in this country. Every day entries are coming in to the offices of Major Cohen so that it will not be surprising if when the caravan starts North June 6, there will be close to 100 cars in the line.

In Decatur County, Tenn., the improvement of the roads was halted by a lack of funds—so a corporation was formed by men of means and the roads were built by this corporation upon these conditions: Every five miles is blocked off by a toll gate to pass which costs nine cents. When the corporation is reimbursed, then the road shall be free or the county may pay off the debt and destroy the toll gates at any time.

One important phase of the southern road situation, a phase which makes the upkeep a minor problem comparatively—is the use of convict labor.

In most of the States convicts are kept constantly on the road-repair gangs and this naturally tends to keep the roads in finest condition.

A vigorous fight is being made throughout the South against the non-progressive land owner, who is balking against the improvement of the roads, because of the immediate expense.

The automobile has done this service for that section in the matter of road improvement.

Where formerly one or two bales of cotton formed a big load for wagons, now five and six bales are easily handled over the perfected roads. Not only that, but the truck is rapidly coming to be an integral part of the commercial life of this country and the day when the entire farm product shall be hauled in by this means is not far distant.

With the increasing popularity of the cars themselves, it was only natural that the manufacturing phase of the situation should receive considerable attention. Eight Southern concerns have been formed to produce cars, of which five are actually turning out completed machines.

The following items of current news indicate the breadth of the interest taken in the South with regard to the automobile:

RICHMOND, VA., May 16—Ending in a sprint that could hardly have been more spectacular, the *Times-Dispatch* endurance run was concluded in this city, two hours ahead of schedule. A Hudson, Chalmers, Reo, Buick, Rambler and a Stevens-Duryea finished with clean scores and were named as winners of their several classes. Thirty-three cars competed and the affair proved to be a big success in every way.

ATLANTA, GA., May 16—A Southern automobile company, backed by men worth many millions, but capitalized at $200,000, as a starter, all of which will be paid in before the first car is on the streets; and a company that will make practically all of its parts, save bodies and wheels, has been launched in Atlanta.

This company is called the Primo Motor Company.

The motors will be turned out by the Van Winkle Gin and Motor Company, which has a million dollar plant in Atlanta, another one almost equally large in Gulfport, Miss., and which sends cotton gins 'round the world. The building in which will be made the Primo motor is located on the Van Winkle property, on the Southern and Western and Atlantic railroad lines and it is already nearly completed. The building and the machinery cost about $50,000. The assembling room will be built near the motor factory and will be a building so designed as to allow 200 or 300 cars to be handled a year. Application for a Selden license will be made.

The first machine turned out will be a roadster. It will have 110-inch wheel base, 36-inch wheels, a 4-cylinder engine and a horsepower of 25-30.

This car will be sold for $1,250. Later on a touring car will be added to the string and this will sell for $1,400.

The Primo line will make a special bid for the Southern trade because of its option of standard and wide treads, because of high power, strong frame and high wheels.

The first demonstrator will leave the Van Winkle works in 30 days and regular deliveries are being promised for 90 days. These will be the 1911 models and about 200 will be made.

The officers of the company are E. Van Winkle, president; J. F. Eskew, vice-president; W. O. Field, secretary; Ed. A. Cerf, treasurer; J. J. Murphy, fiscal agent; Henry S. Miles, Ed. M. Pearce, directors.

ATLANTA, GA., May 16—Despite the fact that the spring races of the Atlanta Speedway were far from the financial success that the promotors desired, the Atlanta Automobile Association is going right forward with plans for a meeting next fall.

Though the track, at present, holds more than its share of the American speedway records, an attempt will doubtless be made before fall to add considerably to its speed possibilities.

The chief weakness in the track is the fact that the turns are not banked high enough for fast moving cars.

While the meet was in progress the project was discussed of making the turns out of timber, like the Los Angeles track.

An effort will be made to change the dates assigned to Atlanta for the fall meeting. The present dates awarded by the A. A. A. are Oct. 17, 20, 21 and 22.

The program of the fall meeting will contain fewer long races than any of the others and more events for high-powered cars than ever before.

The prospects for general success is flattering as interest is at a high pitch with regard to the meeting. The announced policy of the management is expected to bring a flood of entries.

News Notes from the Quaker City

PHILADELPHIA, May 16—State Senator McNichol, in an effort to raise money to carry on this municipality, whose financial affairs are somewhat tangled, sees a chance to add possibly $300,000 a year to the exchequer. He proposes to introduce a bill into the next Legislature providing for the taxing of all automobile owners, the money to be returned to the counties from which it is derived.

The Senator thinks every man owning a car costing $1,500 or less, should be assessed at least $15 per annum; owners of cars listed at from $1,500 to $3,000 should pay $20 and all over the last named amount $25 per year.

"Such a law," says the Senator, "would be of material assistance to the counties in maintaining public roadways, and no class of drivers should be more interested in keeping up the highways or more willing to bear their fair share of the expenses of maintenance than automobilists."

Naturally motor car owners all over the State fail to enthuse over the Senator's scheme; but he's going to introduce the bill next Winter, just the same. J. A. Wister, president of the Philadelphia Automobile Trade Association, thinks motor car owners are already shouldering their fair proportion of such expense.

"The license tax," he says, "already nets the State from $5 to $15 per car, according to the horsepower, in addition to which automobile dealers pay a mercantile tax, just the same as any other business men."

The first step in the promotion of the annual 200-mile Fairmount Park race was taken last Thursday when the Quaker City Motor Club was granted permission to use the park roads for that purpose by the Fairmount Park Commissioners. The same rules that governed last October's successful race will obtain next Fall. The Department of Public Safety will be asked to supervise the police arrangements, and the net proceeds from the sale of grandstand seats and parking spaces and from other sources—they amounted to upwards of $8,000 last year—will be donated to the public charity or charities named by the Department of Public Health and Charities.

Last year's unprecedented success made the work of securing the necessary permission very easy for the club officials—the commissioners were a unit in declaring themselves in favor of it. All hands seem to recognize the prestige the race gives Philadelphia.

Entry blanks are out for the annual Spring race meet of the Quakers at Point Breeze track, Saturday, June 4. Seven events will be on the program, including a 50-mile race open to the fastest cars in the country.

The Quaker City is to have a motordrome. The Philadelphia Motordrome Association, with a capital of $2,000,000, has been incorporated under New Jersey laws, and will build a two-mile track at Clementon, N. J., about 12 miles from the City Hall. The plans contemplate an oval of solid concrete, surfaced with champed vitrified brick, with an immense grandstand capable of seating 25,000 people, and big "bleachers" with a capacity of 30,000, garages, a big fireproof hotel, an administration building, two club houses—one for auto enthusiasts, the other for sky racers—a high-power electric plant and other accessories are a few of the adjuncts of the proposed plant.

Among those interested in the project are A. C. Patterson, president Excelsior Trust Company of Philadelphia; H. S. Reed, assistant treasurer Union Trust Company, Philadelphia; Louis Kuehnle, president Marine Trust Company, Atlantic City; M. R. Margerum, secretary Interstate Fair, Trenton; M. C. P. Parker, Harry J. De Bear, E. L. Bixby, C. E. Folmer, Frank G. Cassler, W. H. Woodward and George H. Robertson, the famous racing man, under whose supervision the track will be built. Milligan & Weber are the architects, and S. Boyer Davis, attorney of the Automobile Club of Philadelphia, and Weaver & Drake, are the counsel of the association.

The annual roadability run of Philadelphia Premier owners will be held on Saturday, June 11, with Cape May, last year's objective point, as the destination. The route selected this year will include many of the roads traversed by the recent successful run of the Motor Club of Harrisburg on the second day—May's Landing, Vineland and Millville being among the points on the route. The Harrisburg run proved such an object lesson to the road authorities in South Jersey that they are hastening to put the few bad stretches in shape before the Premier run.

Many brush agents, sub-agents, and owners in this section drove to Reading last Saturday to partake of the hospitality of the G. M. Britton Company, agents for the car in that section. A banquet at the Mansion House was the chief feature of the entertainment.

G. Hilton Gantert, who handles the Stearns here, has just acquired the sales rights in Philadelphia and adjacent territory for the Ohio car, a Cincinnati product.

News from South Bend and Vicinity

Work on the construction of the new addition to the Widaman garage at Warsaw, Ind., has been commenced, and the building will be rushed as rapidly as possible. The new addition will be 50 feet long and 60 feet wide and two stories high. The addition which will be when completed one of the substantial and artistic buildings of Warsaw will comprise a show room for new automobiles, about 50 feet square, and an office on the ground floor. The second floor will be used as a workshop, an elevator being used to lift the machines to this floor.

The electrical department of the Wood Electric and Manufacturing Company of South Bend, which was sold last January to F. G. Rapp, of Fort Wayne, is being moved to Fort Wayne. The department was disposed of by the Wood company in order to make room for the increase in the business of manufacture of automobile engines. The Wood company began the manufacture of automobile engines a few years ago and its business has increased to such proportions there was not sufficient space for the growing electrical department; by the disposal of this the floor space has been increased 25 per cent. W. F. Wood, head of the concern, stated the company is receiving more orders for engines than can be filled.

Motoring Lively in Winnipeg

WINNIPEG, MAN., May 16—One of the most notable features in connection with the automobile trade in Western Canada this spring is the preparation by the Brush Canadian and the Canadian Overland company to undertake the assembling or manufacture of their cars in this country. Work has been commenced on a large factory at Regina, Sask., which will be rushed to completion.

The program for the automobile race meeting here in July has been finally drafted and decided upon. It will consist of six events, including one for the motor cycles, as follows:

Class A.—Cars not exceeding piston displacement of 160 cubic inches. Class B.—Cars not exceeding piston displacement of 230 cubic inches. Class C.—Cars not exceeding piston displacement of 300 cubic inches. Class D.—Cars not exceeding piston displacement of 450 cubic inches. Class E.—Commercial cars, ope[illegible] Class F.—Motorcycles, open.

Parry C[illegible]

St. Louis News of the Week

ST. LOUIS, May 17—The Major Motor Company is one of the newest arrivals in the St. Louis field. The company has leased the building at 1512 Locust street and is installing one of the most handsome garages and display rooms in the city. The Major company has the agency for St. Louis and most of Missouri, also a part of Illinois, for the Pennsylvania Company of Bryn Mawr, and the Herreshoff Motor Car Company of Detroit.

The St. Louis Automobile Club has sent out entry blanks for the one-day reliability run it is to give June 4 to every car owner in St. Louis. The run is to be for strictly amateur drivers and is to cover the most beautiful parts of St. Louis and Jefferson counties. James Hagerman, Jr., has donated a cup for touring cars and Edward J. Walsh a cup for roadsters. The entries will close May 31. The run is to start at 8 a. m., from in front of the club's headquarters in the Planters Hotel. It is open to stock cars only. It is expected that at least 100 cars will enter the run.

The Buick car "Red Wing," the official pathfinder for the St. Louis Manufacturers' and Dealers' Association, which started out Monday to chart the course of the three days' reliability run to be given June 28, 29 and 30, has been meeting with a rousing reception all along the line from good road enthusiasts. The car is driven by Frank Delaney. F. L. Robertson is another Buick representative on the trip. J. F. Foland represents the cup donors and Ralph B. Campbell the Manufacturers' and Dealers' Association. Mr. Campbell is charting the route and will make representations to the contest committee. The pathfinder car, it is expected, will have completed its trip by Saturday night. However, it may not return to St. Louis before Sunday. It has been decided that cars may be entered in the contest only by members of the association, but non-contesting cars will be welcomed in the run to any number.

City Comptroller Taussig has figured out that two automobiles, at a cost of $2,500 each, will save the city of St. Louis $14,400 a year, and, consequently, has ordered two cars which will take the places of sixteen men hitherto employed as street inspectors. By this means, Mr. Taussig declares the annual increase in taxes for the maintenance of the city will be greatly reduced. Mr. Taussig hit upon the automobile as a means of economizing when he looked over the long list of street inspectors on the municipal pay-roll. Upon inquiring why so many were needed it was explained that the men had to make their visits by street car and that, owing to the number of stops made by the trolley cars, and their inability to reach the points the inspectors have to visit, such a great number had become necessary.

Mercer Car on Transcontinental Run

Early Monday morning a 30-horsepower Mercer car left New York on its arduous trip from coast to coast with Los Angeles as its objective point. The car is in charge of C. H. Bigelow, a well-known western pilot, who expects to set a new world's record for the distance.

Aside from the missionary road work, Mr. Bigelow intends to lower the time record from New York to the coast, of 362 hours Mr. Bigelow will travel but twelve or fourteen hours daily and will drive the car as far as New Mexico, where he will be met by Harold Hanshue, who will run the remaining distance of 800 miles. The distance for the entire trip of the Transcontinental Endurability Run is approximately 3,000 miles.

Will Tour to Indianapolis Races

COLUMBUS, O., May 16—Entry blanks for the reliability contest to be run under the auspices of the Columbus Automobile Club from Columbus to Indianapolis have been completed by the contest committee, of which Arthur M. Crumrine is secretary.

The run will start Friday morning, May 27 and the first day's trip will be to Richmond, Ind., where the night will be spent.

The second day's journey will bring the party to Indianapolis, where the races on the motor speedway will be attended. The return trip will be made in one day and the departure will be June 1. Already two dozen owners have entered their cars in the contest, which will be conducted under the rules of the A. A. A. It is expected that 40 cars will be in the contest.

ork City, of the Mercer Car, Which Will Cross the Continent to Los Angeles

Convict Labor for Michigan Roads

GRAND RAPIDS, MICH., May 16—With about 100 delegates from various portions of the State present, the third annual convention of the Michigan State Good Roads Association was held in this city May 12. The following officers were elected:

President, Philip T. Colgrove, Hastings; vice-president, N. P. Hull (master of the State grange) Diamondale; secretary and treasurer, Thomas M. Sattler, Jackson; former presidents William W. Todd, of Jackson, and Horatio S. Earle, of Detroit, will act with the officers as an executive committee.

The chief subject discussed at the meeting was the bringing about of a better system of highways without burdening the taxpayer with unreasonable taxes. The solution decided upon was the employment of convict labor on the highways.

In Michigan there are vast deposits of trap rock, one of the best of materials for the construction of highways. This rock, it was advocated, might be crushed through the use of labor from the penitentiaries and used to good advantage in the construction of new roads.

In his address, Mr. Todd advocated the establishment of road signs. He favored national aid in the construction of roads. Governor Fred M. Warner told of the growth of the good roads movement in the State, and Townsend A. Ely, state highway commissioner, advocated the use of convict labor. Robert H. Davis of the Detroit Motor Club pledged the aid of the automobilists of the State to the good roads cause and suggested a joint convention of the good roads association, the State grange and the automobile clubs to consider the matter.

At Holland City the ordinance regulating the speed of automobiles at eight miles an hour in the business district and fifteen miles an hour in the residence district has been declared invalid, the new Michigan statute superseding it.

G. A. Horner, general manager of the Rapid Motor Vehicle company, at Pontiac, is authority for the statement that, because of the lack of residences for workmen, the company has been forced to abandon many plans for improving and enlarging its plant. He says that the company needs 1,300 more men to handle its work.

At a meeting of the Hayes-Ionia Auto Body company, the following officers were elected: President, H. J. Hayes; vice-president, T. B. Preston; secretary, W. Q. Loomis; treasurer, W. B. Heath. The directors are F. W. Green, W. B. Heath, T. B. Preston, and W. J. Loomis of Ionia, H. J. Hatch and H. H. Smith of Detroit, and J. N. Willis of Toledo, Ohio. The capital is $150,000, of which $80,000 is preferred stock and $70,000 is common.

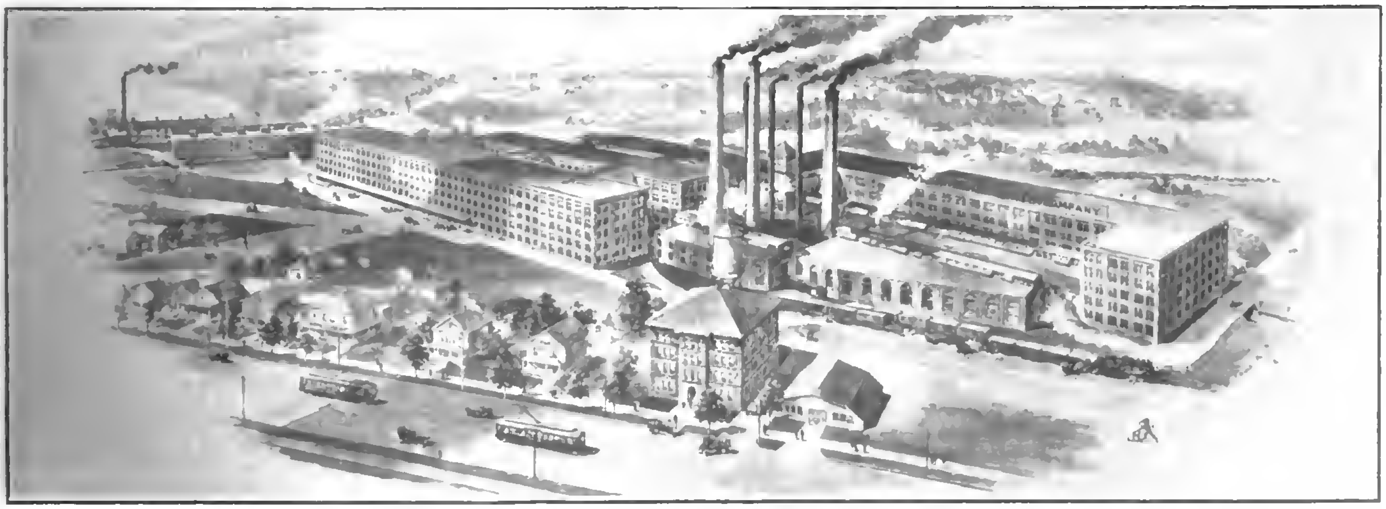
Motor Notes from Hoosierdom

INDIANAPOLIS, May 16—A three days' trade extension trip in motor cars will be made by the Indianapolis Trade Association, starting from Indianapolis May 31 and visiting a number of Indiana cities. The purpose of the trip will be to interest merchants in the cities visited in the products of Indianapolis factories and merchandise of wholesale and jobbing concerns of this city.

There is considerable doubt as to whether the American Motor Car Company, now in Indianapolis, will move its plant to Lafayette, as business men of the latter city and owners of the factory have been unable to agree on terms. The company, it is understood, has asked for a plant and equipment to cost $125,000 and a working capital of $100,000. Lafayette bankers, however, insist that with $125,000 invested in the plant, it would be impossible to advance more than $60,000 for working capital. They have suggested that the company modify its factory plans so that $100,000 working capital will be available, but so far these terms have not been accepted.

The newly organized Indianapolis Auto and Aero Club which has more than 200 members and is striving toward the 1,000 membership mark, is planning to place guide posts on all roads leading out of Indianapolis. These posts will be nine feet high and of iron. They will be placed half way of the route to Chicago, and also on all other highways leading out of Indianapolis. The campaign for membership is being carried on in every section of Indiana.

Visitors to the Indianapolis Motor Speedway in Indianapolis will see a new, or additional scoring system this year. Three huge scoring boards are to be erected, so that the score can be seen from all points of the course. Each board will be in charge of three men and will have three sections, each section being able to keep the time of ten cars.



Enormous Factory of the Goodyear Tire & Rubber Company at Akron, Ohio, Devoted Entirely to the Manufacture of Goodyear Tires

Glidden Pathfinder Completes Its Strenuous Task

(*Continued from page 911*)

There is only one reason for delaying any of the improvements which are to aid in bringing about the more extended use of the automobile, and that is represented in the time it takes in overcoming the inertia of the citizen who thinks he knows, but who is willing to admit that his knowledge is in the shape of a child-like inspiration; of actual experience he lays claim to very little, and of interest, it is secondary.

CHICAGO, May 16—Considerable of a stir was caused in Chicago Friday by the arrival of the Glidden pathfinder which marked the completion of the 1910 trail blazing expedition, which ran through thirteen states and on which journey the Chalmers car, in 30 days, covered 2,966 miles.

Not only did the Chicago Motor Club furnish an escort from the Mississippi river but it also showed its enthusiasm by tendering a banquet at the Chicago Athletic Association, which was one of the best motoring dinners ever given in this city.

Chairman Butler of the contest board of the A. A. A. was present, stopping off here on his way to Indianapolis and Detroit in search of Glidden entries.

Following the arrival of the pathfinding party there was a conference which resulted in the change of the date of starting from June 14 to June 15 because of squeezing in an extra day between Dallas and Oklahoma City. The Sunday stops will be at Hot Springs and Kansas City.

In addition to the nineteen entries already made the chairman announced that before leaving New York, he had been assured by W. C. Durant of the General Motors Company, that two Buicks and two Oaklands would enter. Mr. Butler had been informed that the entries of three Cartercars had been sent in, two in the Chicago trophy and the other in the Glidden.

Banquet Given the Homecoming Glidden Pathfinding Car at Chicago by the Chicago Motor Club

What the Glidden Pathfinder Encountered

CHICAGO, May 14—With the arrival of Dai H. Lewis, official pathfinder of the 1910 Glidden tour, and E. L. Ferguson, special representative of the American Automobile Association, in the Chalmers car here on Friday noon, May 13, the official laying out of this year's route which will be the longest in the history of the tour was completed, the speedometers showing a total of 2,851 miles for the cars which will contend in this year's American touring classic. As THE AUTOMOBILE has been in the habit of presenting an analytic review of the route in previous tours, the same policy is adhered to this season, and in the following paragraphs the general characteristics of the route, as given by Messrs. Ferguson and Lewis, are herewith printed for the general benefit of those manufacturers who have entered this year.

As mentioned in these columns last week, this year's tour embraces territory in thirteen States, seven of which have never before had a Glidden tour enter their confines. While thirteen States make a big total, yet the amount of traveling done in Alabama, Ohio, Mississippi and Missouri is so slight as to scarcely merit mention. On the other hand Kentucky, Tennessee, Arkansas, Oklahoma, Kansas, Iowa, and Illinois are crossed from side to side, whereas Texas and Nebraska are invaded to a slight extent. The average length of each day's run for this year is 198 miles, as compared with 178 last season. Although each daily trip this year will practically be 1 hour longer than last year, yet the pace will remain the same, namely 20 miles per hour for the large cars, 18 for cars listing from $800 to $1,600, and 16 miles an hour for those selling below $800. In spite of this high daily mileage, there are only five days on which the schedule exceeds the 200-mile mark and these trips are over the good-road territory beginning with Texarkana and ending at Davenport, the routes being: Texarkana to Dallas, 217 miles; Dallas to Lawton, 200 miles; Oklahoma to Wichita, 216 miles; Wichita to Kansas City, 234 miles, Kansas City to Omaha, 242 miles, and Des Moines to Davenport, 219 miles.

In contrast with these long runs are several short ones, namely, Cincinnati to Louisville, 162 miles, Nashville to Sheffield, 119 miles, Hot Springs to Texarkana, 131 miles and a Sunday morning run of 60 miles from Little Rock to Hot Springs. E. L. Ferguson, who made a careful comparison of the route with that of last year, asserts that it will be an easier one on cars in that there is not that long stretch of trail over the plains which was encountered last year through western Nebraska, Colorado, and western Kansas. There are, however, several physical conditions different from those experienced in any previous tours. One of the most noteworthy of these is the creek situation encountered in the Nashville vicinity, and also in the region of Hot Springs. Before entering Nashville and after leaving the city, the roadway is crossed by a series of unbridged creeks, which in dry weather are never more than 3 or 4 inches deep, but after rain of a day or a day and a half these become swollen so that it is impossible for a car to cross them.

The first creek begins 50 miles north of Nashville, and in all there are from 40 to 50 of these within a radius of 50 miles of the city on the route traversed. Should a heavy rain precede the arrival of the cars in this district it will mean a delay of, perhaps, a day before the creeks subside, because by actual measurement it was noticed that they fall at a rate of 3 inches to the hour. These creeks are from 3 to 8 miles apart. The bottoms are soft soil. The creeks in Hot Springs and vicinity are considerably different; these streams range from 2 to 10 feet in width and have clear water with gravel beds. They are close together, many of them not being one-third mile apart. Authorities in Hot Springs and Little Rock are arranging to bridge a lot of these. The Hot Springs Motor Club has raised $1,000 for the work and has influenced the Little Rock and other clubs to donate $1,500 for the work, so that by the time the tour passes these culverts will be bridged over many of the 30 streams.

Another particular novelty that will be encountered this year is the ferry situation, as on three occasions the contesting cars will have to be ferried across large rivers. The first ferry is at Helena on the Mississippi river. The river at this point is very wide and the cars will be transported on large flat-top lumber barges which barges are 150 feet long and 30 feet wide, offering accommodation for thirty cars on each. These barges will be moored on the east bank of the river, and after all of the cars in the tour are loaded they will all be transported across the river together. At this point the levee, or artificial bank on the east side of the Mississippi is 15 feet high, and the Helena authorities will have openings cut through so that no difficulty will be encountered in loading the cars.

The second ferry is at Clarendon, Ark., where the White river is crossed. This is the scene of the famous pearl fisheries. The river is but one-quarter mile wide and at present the only crossing facility is a ferry which will carry three cars. The Helena people are coming to the rescue and expect to float one or two of the large lumber barges from Helena down the Mississippi and up the White river, a distance of 200 miles, so that the ferry problem at Clarendon will be favorably solved.

The third ferry is at Fulton, Ark., where the Red River is crossed. Fulton is but 20 miles out of Texarkana. As the river is but one-quarter mile wide, the one ferry with accommodation for six cars will prove adequate, as it requires but four minutes to make a round trip of the ferry.

In a progressive review of the general road conditions, beginning with Kentucky, it is sufficient to say that all of the roads in this State are macadam or pike as the natives term them, and the run across the State can be made on schedule, whether rain or shine. It was expected that the trip across Kentucky would embrace the famous Blue Grass country, but only the margin of it is touched upon, and that in the Louisville vicinity which is a noon stop for the first day. A 90-mile circuit through the heart of this Blue Grass territory was contemplated but it was eliminated.

The run across Tennessee will not prove so pleasant a trip, the creeks already spoken of being one of the conditions. In this creek territory, however, the roads are of gravel and there will be no trouble in maintaining schedules. Nashville has to date proven rather lukewarm on the improvement of roads, but it is hoped that in the next month some enterprise will be shown. It is impossible to predict what the nature of these roads will be like in June because there had been a cloud burst when the pathfinder passed through, and it was delayed more than a day in some places. Generally speaking, the Tennessee roads are not comparable with those in Kentucky. South of Nashville and extending nearly to Columbia is a particularly bad stretch, and between Columbia and Sheffield a second bad stretch will be met.

The fourth day of the tour, from Sheffield to Memphis, will offer some difficulties through the wooded territory, but the last 22 miles out of Memphis is one of the best macadam boulevards in the South. The spirit of touring is not developed in Memphis to the extent it should be, and while there are miles of good road in Shelby county, in which the city is located, it is stated there are not over three motorists in the city who have taken a 100-mile tour in the outlying district. Memphis as a city is growing steadily, and it is expected that once the touring spirit is developed the good roads cause will be greatly advanced. The 4-hour run through the stumpy region on this day's tour will be a good test of cars.

The run from Helena to Little Rock begins through the Buckshot land, which is a level territory similar to the gumbo regions of Iowa. For three hours the tourists will pass through the rice country, where at that season the plants will just be emerging through the top of the water. Once this rice country is passed, the cars will have a three-quarter mile climb of 6 per cent. grade which is on to the tail end of the Ozark mountains, where they are tapering off to the level land. In all there will be two or three of such ascents, none of which will offer any difficulty. Once up these grades it is practically easy going to Little Rock. This territory offers an excellent car market, the pathfinders reporting many towns along the route in which five cars were owned in 1909 and already forty-two or more have been sold up to date.

The Monday run from Hot Springs to Arkadelphia will be one of the hardest days on the trip. Originally it was to be a trip of 191 miles, but owing to the 60-mile run from Little Rock to Hot Springs being made on Sunday, the Monday trip will be reduced to 131 miles. Of these remaining 131 miles 80 are particularly hilly, these hills ranging from one-quarter to one-eighth mile in length and some with grades as high as 20 per cent. This is one of the poorest selling sections of the trip, the country being wooded nearly all of the way. Once Arkadelphia is passed the troubles of the tour are over, so far as roads are concerned, the remainder of the run to Chicago being through continuous agricultural territory. To Texarkana the road is level, and through a cotton and corn country.

At Texarkana, which is on the State line between Arkansas and Texas, the State line passes through the middle of the main street, so that to satisfy the natives half of the cars will be parked on the Arkansas side of the line and the other half on the Texas side. For some miles out of Texarkana some stumps will be encountered on the road, but after Paris is passed, it is nothing but a perfectly level road to Dallas. Pathfinder Lewis reports that the boulevard leading 25 miles into Dallas is one of the most perfect roads encountered. From Dallas to Fort Worth, 32 miles, is a boulevard through corn and cotton country.

From a standpoint of the products of the country the tourists will be treated to a variety of conditions. Through Kentucky the tobacco and stock-raising territory will be seen; in Tennessee the leading products are corn and tobacco; across Arkansas the rice territory will offer particular interest; in Texas cotton and corn are the leading products; and from this point north the tourists will be continually in the great grain-producing center of the country.

A commendable feature of the tour this year will be a half hour noon stop each day at which time the members of the tour will have an opportunity of meeting the people en route, and those manufacturers who accompany the tour will have an opportunity of studying local conditions. The following noon stops will be made: First day, Lexington, second day, Bowling Green, third day, Columbia, fourth day, Corinth, fifth day, Clarendon, sixth day, Arkadelphia, seventh day, Paris, eighth day, Terrell, ninth day, El Reno and Chickasha, tenth day, Enid, eleventh day, Emporia, twelfth day, Marysville, thirteenth day, Guthrie Center, fourteenth day, Cedar Rapids and last day, Rochelle.

Of Interest to Wisconsin Motordom

MILWAUKEE, May 16—Motions to dismiss the suit of the Velie Motor Vehicle Co. of Moline, Ill., have been filed in the circuit court at Milwaukee in behalf of twenty-six of the fifty-five A. L. A. M. concerns made defendants in the action to recover $500,000 damages on charges of conspiracy in restraint of trade and to ruin the plaintiff company. The twenty-six defendants contend that the action was not brought in the proper manner and that service of summons was faulty. All of the defendants making the motion to dismiss the suit are not legally represented in Wisconsin. Service was made on agents representing their products in Milwaukee, when under the law, service must be made personally. The motion was filed by Quarles, Spence & Quarles, attorneys, Milwaukee. Arguments will be heard by Judge W. J. Turner on May 21 at Milwaukee.

Quarles, Spence & Quarles are now preparing briefs for the remaining companies and these will be filed in two or three weeks' time. The natvre of the answers is not known and no information on this point will be permitted to escape before the day of filing the papers.

For 1911 the Kissel company plans to build an electric car and a line of motor trucks and delivery wagons, in addition to the line of gasoline pleasure cars now built in eleven models.

The only information given out regarding the new Kissel electric is that it will be produced in large quantities for next year and will be a shaft-drive car.

The ranks of the Wisconsin State Automobile Association, have been strengthened by the addition of another club, the Oakfield Automobile Club. This organization is composed of owners at Oakfield, South Byron and Brownsville in Fond du Lac County, Wis. The club has twenty-two charter members. The officers are: President, Dr. C. H. Moore; vice-president, W. C. Ehrhardt; second vice-president, Henry McCarty; secretary, W. E. Bristol; treasurer, George Hansen. It was decided to hold meetings each month. Good roads and checking of law violations are two important aims of the club.

Charles L. McIntosh, of Milwaukee, Wis., president of the Pierce Motor Co., of Racine, Wis., and other corporations, who died at Naples, Italy, recently, left an estate valued at $300,000. The bulk of estate is put in trust for the children and their issue. The will was filed at Milwaukee on May 13.

The Wisconsin Automobile Radiator Co. has been incorporated by Milwaukee capital with a stock of $50,000. The incorporators are: H. Gerhard Aussen, S. S. Land and Arthur Zancing.

The Mitchell-Lewis Motor Co. of Racine, Wis.. made a shipment of two Mitchells to Antwerp, Belgium, one day last week. Foreign shipments are now almost a daily occurrence.

Arthur N. McGeoch is building a fine private garage at West Allis. The building is 58 by 24 feet in dimensions set in a miniature park, part of the McGeoch estate. The building will be of concrete, ornamentally designed.

The State of Wisconsin has started another suit to test the constitutionality of the oil inspecion law, by making Thomas B. Jeffery & Co., of Kenosha, Wis., and individual officers of the corporation defendants. Chief Oil Inspector is trying to collect fees for testing 686 barrels of gasoline purchased by the Rambler concern for its own use. Experts for the company declared the tests to be valueless.

Fine Trophy for Wisconsin Tour

MILWAUKEE, May 16—The accompanying cut shows the beautiful silver trophy donated by Charles F. Pfister, proprietor of The Milwaukee *Sentinel*, to the Wisconsin State Automobile Association. The cup will be awarded to the winner of an annual reliability tour, and will be held by him until the succeeding year. It is a permanent or perpetual trophy. It is known as the "Milwaukee Sentinel Trophy."

The cup stands twenty-four inches high and is eighteen inches wide at its greatest breadth. It is of solid silver, the bell being finished in gold. Beyond the usual lettering of the inscription, there is no engraving on the cup, all figures being done in high bas-relief. The cost was more than $600.

"Sentinel" Trophy for Milwaukee Run

The Rambler has been selected as official pathfinder for the tour.

Matthew C. Moore, president of the Wisconsin State A. A.. who was appointed official pathfinder, will leave Milwaukee May 18 or 19 and will attempt to make the trip in schedule time of five days. The tour will start July 18 and end in the evening of July 23. The A. A. A. has sanctioned the tour.

George A. West, believes that more than seventy-five cars will be nominated.

State Association in Tennessee

NASHVILLE, May 16—President H. S. Probasco, of the Chattanooga Automobile Club, the oldest organization of the kind in the State, has been authorized to take up with other cities of the State the question of organizing a State Club. Delegates will be sent to some one of the cities at a date to be named later and the club will be launched for the purpose of cementing the automobile interests.

The Nashville Automobile Club will meet this week and finish its organization. It is the wish of the local club to co-operate with counties in Tennessee and Kentucky to improve the highway along the route of the Glidden Tour.

Maryland Hill Climb June 11

BALTIMORE, MD., May 16—It was decided at the meeting of the Automobile Club of Maryland that the date for the hill climbing contest will be June 11. Chairman Joel Nassauer announced that the Belvidere Hill, extending from Roland avenue to the Falls road, had been selected for the event. This is one of the steepest hills in this vicinity outside the city limits and was used two years ago when a successful hill climb was given under the club auspices. There will be ten events. The official entry blanks were posted last Friday.

"Little" Glidden Pathfinders

MINNEAPOLIS, May 16—The pathfinder car of the "Little" Glidden tour, for the St. Paul *Dispatch* trophy, left St. Paul Saturday afternoon. The car is an E-M-F "30" and was driven by T. M. Skeggs. From St. Paul the road was to Northfield. to Faribault, 25 miles and from Faribault to the first stopping point, Owatonna. 34 miles farther.

Trucks Will Climb Dead Horse

COMMERCIAL cars and trucks will have a chance to show their paces in the line of hill climbing when the Worcester Automobile Club conducts its contest on Dead Horse Hill, June 4. Twenty events are on the program and one of them is solely for the commercial vehicles.

The full list of events is as follows:

Class "A."—Open to any gasoline motor car (other than motor cars with solid tires, wheels 36 inches in diameter and over) which complies with the definition "stock car," this class to be run in the following divisions:

1A. $4,000 and over.
2A. $3,001 to $4,000.
3A. $2,001 to $3,000.
4A. $1,601 to $2,000.
5A. $1,201 to $1,600.
6A. $801 to $1,200.
7A. $800 and under.
8. Open to all makes of motor cycles.
9. Free for All. Open to cars of all types and motive power.
10. Amateur Event. Owners to drive. Worcester County Championship for trophy to be won 3 times in succession.

Class "B."—Open to any chassis of a gasoline car which is in accordance with the definition of a "stock chassis"; to be governed by the following table of piston displacement and minimum chassis weights:

	Piston Displacement in Cubic Inches.	Minimum Weight in Pounds.
11B.	160 and under	1,100
12B.	161 to 230	1,400
13B.	231 to 300	1,700
14B.	301 to 450	2,000
15B.	451 to 600	2,300
16B.	601 to 750	2,500

17. Open to commercial cars and trucks. Details to be an announced later.
18. Free for all gasoline stock cars only.
19. Record of hill.
20. Amateur Event. Gasoline cars only; no limitation as to territory.

J. P. Coghlin, chairman of the hill climb committee, will be in charge of the event. Fred J. Wagner will wield the starter's flag. Prof. D. L. Gallup, of the Worcester Polytechnic Institute, will have charge of the timing.

Many Enter Norristown Run

NORRISTOWN, PA., May 17—With thirty entries in the various manufacturers' classes and a total entry list of fifty-five automobiles in the reliability run of the Norristown Automobile Club which starts tomorrow on a two-day tour to Scranton and return, will be an event of notable size.

The itinerary of the first day will be 150.8 miles. The night stop will be at the Hotel Jermyn, at Scranton, and the return trip will be 175.8 miles. The technical requirements of the tour are severe and the course is specially adapted to give the cars a thorough test. The entry list includes:

Class A—Touring cars, valued at $2.001 and over:—	
Pullman	Selden
Franklin	Matheson
Pullman	Kline

Class B—Touring cars, valued at $2,000 and under:—	
Regal-Detroit	Inter-State
Inter-State	Enger
Regal-Detroit	E-M-F
Maxwell.	Kline

Class C—Runabouts valued at $2,001 and over:—	
Alco	Jackson
Palmer-Singer	Buick
Knox	Premier

Class D—Runabouts, valued at $2,000 and under:—	
Warren-Detroit	Mitchell
Ford	Overland
Ford	Parry

Georgia Car Wins Hill Climb

DUBLIN, GA., May 16.—The automobile hill-climbing contest was won by a White Star, a Georgia-made car. The contest took place at Turkey Creek hill, one of the hardest in Laurens county to climb, and was made from a flying start on the last bridge on the western side of the creek. C. W. Brantley and Frank N. Watkins were the official timekeepers. The winner was driven by Charles Eberlein. Following are the records: Buick, R. L. Miller, 37 sec.; White, Marshall, 37 sec.; Ohio, Sam Bashinski, 40 sec.; E.M.F., Marshall, 42 sec.

Continental Tires on Winners

One of the interesting places at the recent 24-hour race at Brighton Beach was the camp of the Continental tire outfit. The winning Simplex car and the Stearns that finished second, both used these tires, the former traveling fifteen hours on one of its set. Changes were made with the demountable rim in some instances in less than a minute.

The Selden car, equipped wih the Continental heavy, flat tread, experienced no tire trouble throughout the race to one of its set.

Isotta Won Coast Road Race

COALINGA, CAL., May 9, Special Telegram—In a field of eight an Isotta won the 105-mile road race here to-day by a lead of about 30 miles over the second car. The Isotta, Marquise driving, negotiated the distance in 2 hours, 15 minutes and 6 seconds. A Buick finished second and a Regal third. When the Isotta finished, after having lapped every other car in the race once and sometimes twice, Buick 16, driven by Nikrent, which was second had two laps, or 30 miles yet to do. The distance of each lap in this race was about 15 miles over rough roads. The entries included the Pope-Hartford, Elmore, Isotta, Regal, Winton, two Buicks and a Mitchell. On the preceding day a Winton six, Free driving and starting seventh in a field of eight, won the Fresno-Coalinga road race in 1 hour, 11 minutes. 43 seconds, clipping 13 minutes off the record held by the Buick. The distance between the towns was 64 miles. Murray in a Buick blinded by the dust crashed into the rear end of a touring car. The car was wrecked but he escaped with bruises about the head.

Pullman Makes Good on Road

The showing of the Pullman model K entry in the recent Harrisburg run to Atlantic City, which made a clean score in Class A and which will get the chief trophy in that class, has been gratifying to the manufacturers. The run was accomplished in rain during two days and road conditions were such that the stability of the contestants received a thorough test.

Continental Tire Camp at Recent Brighton Beach 24-Hour Race

Characteristics of Model 38 Overland

(*Continued from page* 931.)

valve V is ready at hand when it is desired to light up. There are many other points of interest which might be brought out, which will be reserved for some more propitious time, but it will be in order to state the main dimensions of Model 38 before concluding this effort.

The car sells for $1,000, and has a motor which is rated at 30 horsepower. The cylinders, of which there are four, have a bore of 3¼, and a stroke of 4½ inches. The motor is water-cooled, works 4-cycle, has a celluloid type radiator, no water pump, and the individual cylinder construction, together with other notable features of design, rather leads to the conclusion that the expertness of the driver is in small demand. Ignition is effected by magneto; a coil and battery auxiliary will serve during cranking, and should some other occasion arise. Ordinarily, this model is fitted out as a runabout, but for this occasion it was necessary to make provision for the long trip, and Fig. 1 shows how this matter was attended to. Quite a little storage room for tools and "togs" was provided in a simple and secure manner.

With all the eclat of a social function, Miss Blanche Stuart Scott in her Overland 38 commenced her long tour from New York to San Francisco Monday afternoon. Miss Scott undertakes the trip without male help of any sort and is accompanied by a girl friend only. The trim car, white-painted and bearing the sign "The Girl, the Car, and the Wide World," attracted a vast amount of attention in the preliminary run and Miss Scott was called upon to acknowledge numerous greetings.

The tour is unusual in that it is the first of its kind ever undertaken by a woman. She is brim full of enthusiasm and confidence and the anticipation of any big obstacles is apparently far away from her thoughts.

Miss Scott was tendered a luncheon at the Hotel Claremont before the official commencement of the trip. The guests included representatives of the press and the Overland company and everybody joined in wishing the voyager good luck and a pleasant trip. About 3 o'clock, the young woman cranked her motor and stepping into the car with her friend, turned its radiator northward. Waving goodbye to the assembly, she was off on the first leg of the tour that may take months to finish.

There is to be no definite itinerary or time limit. The fair driver can be as leisurely as she pleases; the only condition involved in the trip being that she shall receive no assistance from male persons along the way in the shape of repair work.

Her first objective point is to be Albany and from thence her course will be westward along the South shore of Lake Erie. Between here and Chicago five automobile clubs are preparing to receive the tourists and entertainments at numerous country clubs by the women of half a dozen cities are being arranged.

In reply to the good wishes expressed by the guests at luncheon, Miss Scott said: "It's starting in a pleasure jaunt but we are going through."

Metropolitan Automobile Guide Is Progressing

The growing demand for specific touring information for the use of those owning or operating cars in the neighborhood of New York City has induced the Automobile Blue Book Publishing Company, 231 West 39th Street, New York City, to bring out a second edition of the well-known metropolitan automobile guide. The new volume will be brought up to date in every particular, and last week the three Blue Book cars, Nos. 1, 2 and 3 started out in different directions to prepare route matter for the new book. The book will be limited to one and two-day trips around New York City trips that can be enjoyed on a Saturday and Sunday run. In every case possible every trip will have the return route by other roads than those taken on the trip out, and particular effort will be made to describe routes that will make the various trips real outings. The new book will be gotten up in the usual high-class Blue Book style.

A. L. A. M. Tire Committee to Meet

One result of the big meeting of the A. L. A. M. earlier this month has been the calling of a meeting of the tire committee of that organization for May 24. At this meeting the tire committee will consider general and detailed plans for avoiding difficulty arising out of the present state of the crude rubber market as it applies to the problem of tires for 1911.

The attitude of the manufacturers as expressed at the meeting was amicable toward the rubber men and it was freely predicted after adjournment that a working basis would be found upon which both factors would be able to work.

Three More in United States Motor Company

Another series of mergers has developed this week, affecting the United States Motor Company. The Gray Motor Company, of Detroit, makers of marine and stationary engines, the Brush Runabout Company and the Briscoe Manufacturing Company, both of Detroit, have been added to the United States Motor Company.

Worcester Show Attracts Entries

WORCESTER, MASS., May 16—Thirteen automobile entries have been received for the Horse, Auto and Motorcycle Show to be held at the Sturbridge fair grounds, Saturday, May 21, under the auspices of Southbridge and Worcester autoists and horsemen. It is the intention of the committee in charge of the show to run several automobile races over the broad half mile track of the fair grounds, providing contestants can be entered before next Thursday night.

Among the entries so far received. the following makes are represented: Franklin, Buick, Overland, Matheson, Chalmers, Knox, E-M-F "30," Ford, Flanders, Peerless, Hudson. and several others.

Southern Interest Keyed Up

NASHVILLE, TENN., April 25—Increased interest in automobiling, the formation of more auto clubs, and the recent visit of the official pathfinder of the Glidden Tour have aroused interest throughout Tennessee in good roads and the various sections are bestirring themselves looking to material improvement in the roads of the State.

Fast Time on Cheyenne Speedway

CHEYENNE, May 16—Fast work was done on the 4-mile circular speedway at the meet last week when Oldfield with a Benz car went a half mile in 17 seconds and the full mile in 36 seconds. The Knox, Darracq and a number of local cars competed. The course is so large that a mile straightaway is possible.

Joins Staff of MacManus-Kelley

Charles E. Jones, advertising expert, who has been identified with Chicago and New York agencies for several years has been added to the staff of the MacManus-Kelley Company, Detroit. Mr. Jones will engage in the automobile advertising section of the concern's activities.

Official Report of Around New Jersey Run

The labors of the checkers of the Around New Jersey Reliability Run are completed and the report is to stand as here given. There are so many perfect scores that, as W. J. Morgan puts it, the one gold medal for the first prize will not go around, and it is suggested that the tie be disposed of by "drawing." If the matter is disposed of in this way, the remaining perfect score cars will be given replica medals. The second and third prizes are in the form of silver and bronze medals respectively. The Motor Contest Association states that the run, taking it on the whole, was a huge success.

Orphans' Day Promises Well

Fifty Pierce-Arrows, fifty Chalmers and fifty Buicks have been definitely donated so far to the Orphans' Day committee for use in the parade of the children to Coney Island. These cars will move in divisions freighted down with joyful kiddies as part of the procession which will stretch from the City Hall to Herald Square. Another division is being formed to consist exclusively of Packard cars, but all details are not complete. The total number of cars donated to date is 182, but that number will be vastly augmented before the event is held. It is planned to accommodate all the 4,000 orphans who have made application and in the event of success, the occasion will be the greatest in the history of the Orphan Day movement.

With characteristic energy, the Long Island Automobile Club is working to make Orphans' Day the biggest success ever scored by that club. Personal appeals to car owners have been sent out by the officers of the club and returns so far have been gratifying. The outing has been set for June 7 and will include a trip to Coney Island, luncheon and informal feasting for the children and a good time in the show place.

Warren Motor Company Dines

DETROIT, May 9.—Officers of the Warren Motor Car Co. were hosts at an informal banquet in the Tuller Hotel, Friday night, the guests being the department heads. General Manager Bayerline presided as toastmaster.

One-minute speeches were made by secretary Allen, superintendent Bollinger, sales manager Wilson, chief engineer W. H. Radford, and forman J. Mohardt and others.

Twenty-one in Connecticut Run

HARTFORD, May 17—Twenty-one cars have been entered for the three-day, 600-mile reliability run of the Automobile Club of Hartford, which starts Thursday.

The first day's run will be through Litchfield county as far as the New York and Massachusetts state lines. The first leg extends as far south as New Milford.

The second leg is through the southwestern section of the state as far as Stamford, while the third day will be given up to the territory east of the Connecticut River. The following entries have been received:

No. 1—Chalmers-Detroit, Carl H. Page & Co., New York, Class 3.
No. 2—Chalmers-Detroit, Carl H. Page & Co., New York, Class 5.
No. 3—Franklin, S. C. Hutchins, Hartford, Class 4.
No. 4—Regal, Regal-Detroit Auto Co., New York, Class 4.
No. 5—Cartercar, W. S. Williamson, New York City, Class 2.
No. 6—Cartercar, W. S. Williamson, New York City, Class 3.
No. 7—Corbin, Corbin Motor Vehicle Corporation, New Britain, Class 5.
No. 8—National, Fred T. Reid, Hartford, Class 5.
No. 9—Jackson, Kilby & Barrett Auto Sales Co., Hartford, Class 3.
No. 10—Franklin, H. H. Franklin Manufacturing Co., Syracuse, N. Y., Class 6.
No. 11—National, Portner Motor Car Co., New York, Class 5.
No. 12—Reo, N. B. Whitfield, New Haven, Class 3.
No. 14—Auburn, La Due Carmer Motor Co., New York, Class 4.
No. 15—Speedwell, Rantz Motor Car Co., Bridgeport, Class 5.
No. 16—Columbia, Columbia Motor Car Co., Hartford, Class 5.
No. 17—Interstate, Holcomb Co., New Haven, Class 4.
No. 18—Franklin, Holcomb Co., New Haven, Class 5.
No. 19—Pierce-Racine, Volney J. Jacobs, Boston, Class 4.
No. 20—Lexington, Nock Auto Co., Inc., Providence, R. I., Willis H. Brew, Class 5.
No. 21—Tiley, C. B., Tiley, Essex, Class 5A.
No. 22—Overland, Fairfield Auto Co., Bridgeport, Class 2A.

Touring Around United States Borders

About a month ago an automobile made by the Inter-State Automobile Company of Muncie, Ind., left the factory on a tour of 25,000 miles all around the borders of the United States. C. L. Welch is driving the car and so far as he has progressed, the trip has been most trying.

The plan was to cross the mountains to Vancouver, B. C., and then proceed to San Francisco and on to Los Angeles. Then strike back into the mountains again and traversing the desert country and the Southern states to the Atlantic seaboard. Following the coast line and back to New York, make the comparatively easy run back to Muncie.

Motor News Makes Its Debut

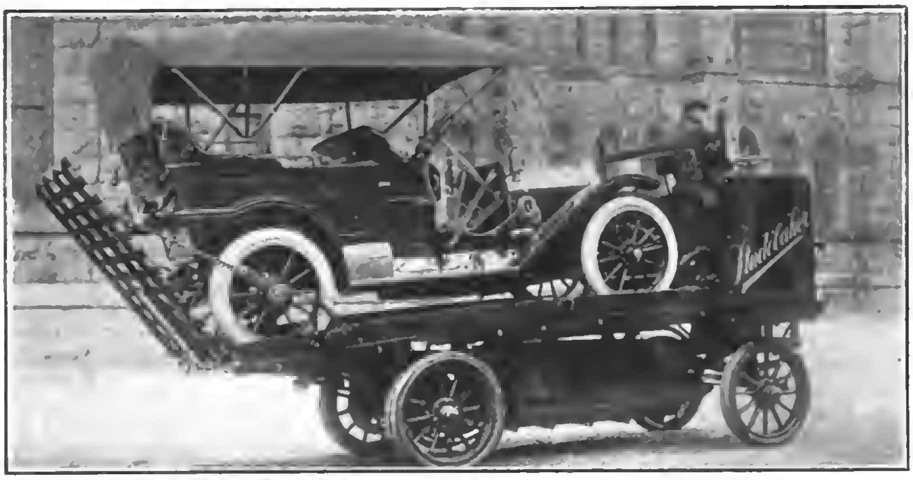
A new automobile publication, *The Motor News*, house organ of the Premier Motor Mfg. Co., has made its appearance. It is a monthly and in size approximates the style of a daily newspaper. The paper is heavy and highly sized, so that cuts make an excellent impression. The material used in the first issue is largely taken from the daily press special articles and is well edited and put together.

Ohio Senator Feels Law's Power

COLUMBUS, O., Apr. 25—The arrest of State Senator Baker of Cincinnati by a Columbus policeman on the charge of operating his motor car without displaying the necessary lights caused quite a stir. According to the state constitution a member of the legislature can not be arrested while the legislature is in session except for treason, a felony or disturbing the peace. The police prosecutor refused to file an affidavit and the case never came to trial.

Federal Registration Progress

WASHINGTON, May 9—Prospects for the passage of the federal registration bill are said to be bright. The petition of Chicago motorists, was presented to the Committee on Interstate and Foreign Commerce this week.



An example of the utility of the modern big truck. Studebaker five-ton truck hauling Studebaker touring car through the streets of New York

In the Realm of the Makers

Cleveland Automobile Spring Company, of Cleveland, O., was incorporated with a capital stock of $2,000 to manufacture motor car springs.

Akron Inner Tube Company, which will manufacture inner tubes exclusively, is erecting a factory. The preliminary capital of the concern is $10,000.

M. D. Coate, Cleveland Ford manager, reports that there will be a convention of Ford dealers of northern Ohio in Youngstown, Tuesday, May 10.

The Fry Manufacturing Company, a concern organized to control the manufacture and sale of the Fry plug, is located at 1779 Broadway, New York City.

The Miller Rubber Company, of Akron, O., has increased its capital stock from $250,000 to $500,000. The company has doubled its capacity during the past year.

The Brown Auto Carriage Company, builders of special bodies for any automobile, moved to new quarters at Thirty-second street and Superior avenue, Cleveland.

The Baker Motor Vehicle Company has moved into its handsome new building in Cleveland, Ohio, situated in the most fashionable and exclusive part of Euclid avenue.

The Sandusky Auto Parts and Motor Truck Company, of Sandusky, O., has been incorporated with a capital of $15,000 to manufacture parts of automobiles, and especially motor trucks.

The Reliance Motor Truck Company, Owosso, Mich., has purchased the land on which to build additional shops, 750 feet long and two stories high, for the manufacture of truck bodies.

The Dayton Rubber Manufacturing Company has decided to increase its capital stock from $150,000 to $500,000 in order to provide for enlarged and augmented facilities for manufacture.

The Cass Motor Company, manufacturing the Cass power truck, will locate in Port Huron, Mich. The concern will occupy the old Grand Trunk shops and employ upward of 6000 men.

Plans are now in the hands of Lansing architects for more buildings at the Reo Motor Car Company's plant, on Washington street south, and it is probable that the work will be begun this summer.

The Monitor Automobile Works have removed from Chicago to Janesville, Wis. The new plant has a floor space of 75,000 square feet, which is a material increase over what was formerly occupied.

The new plant of the Auto Wheel Company at Lansing, Mich., is nearing the stage when machinery can be set in motion. It is expected that the company will be ready for business in about a month.

Work is progressing on the addition of the Buckeye Wheel Company's plant at Galion, Ohio. The new building will be used to house the department devoted to the making of automobile wheels.

The Whitney Manufacturing Company plans for immediate construction of a five-story addition to the present big plant in Hartford, which is to be completed and ready for occupancy by October 1.

Biddle & Smart Company, Amesbury, Mass., are erecting a large addition to their present plant. It will be completed July 1 and will be equipped with machinery for the manufacture of wood and metal bodies.

The Archer Automobile Association announces that it is about ready to place on the market a roadster, four-cylinder, two-cycle, thirty-horsepower, light-weight car. The company's headquarters are at Burlington, Vt.

The Standard Specialty Company, of Cleveland, was incorporated with a capital of $10,000 to manufacture automobile accessories by Harry Dolitz, Cornelius Sheehan, Leo J. Kellosky, Charles M. Robertson and Louis M. Kleinhenz.

The Lowell Auto Body Company has begun the manufacture of automobile bodies in its new plant recently erected in Lansing. The new factory is a substantial two-story brick structure and is equipped with the latest patterns of machinery.

Mcre automobiles were sold in the United States during the thirty-one days of the month of March than in any corresponding period in the history of the automobile industry, according to reports received from many factories now working overtime.

Ionia Wagon Company, which went into the hands of a receiver some time ago, has been sold to the Hayes Ionia Auto Body Company for $70,000. The company already has machinery on the ground, and this will be installed at once. The company has a successful plant at Detroit.

The Universal Tire Protector Co., Angola, Ind., has been reorganized with a capital stock of $30,000 fully paid, the officers being S. C. Wolfe, president; E. S. Croxton, vice-president; J. R. Nyce, secretary, and W. W. Love, treasurer. Mr. Croxton is vice-president of the First National Bank of Angola.

Crowds at Minot's First Show

MINOT, N. D., May 16—The first automobile show ever held in the city has proved surprisingly successful. The show closed last week after enjoying patronage that was satisfactory to the management. The exhibit contained several varieties of well-known cars and quite a large display of parts and accessories. The exhibitors were mostly local agencies and included the following: J. F. Koppin, Minot; C. Foss, Minot; Scofield & Robinson, Minot; Dr. R. W. Pence, Minot; D. Dorman, Minot; More Bros., Fargo and Wimbledon; Abbott-Detroit Motor Car Agency, Minot; Jacobson Implement Company, Minot; Motor Inn Company, Minot, and A. Belzer, Minot. The enterprise had the support of the Minot Commercial Club.

W. C. Durant, of General Motors Company, New York

The Connecticut Shock Absorber Company, of Meriden, Conn., has purchased the tools, dies and stock of the Sager Shock Absorber Company. The former concern announces that the reason for the retirement of the Sager company is that its device was an infringement of the patents held by them.

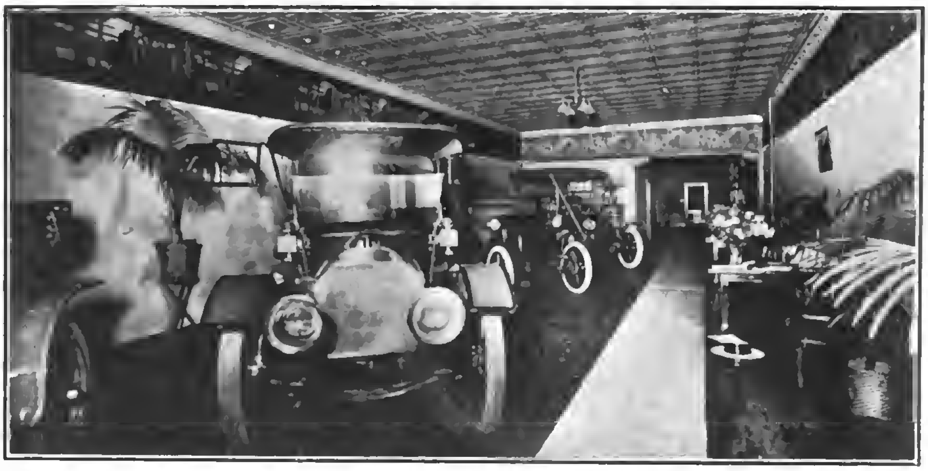
Harry W. Cleveland, of Fond du Lac, Wis., has completed his first full-sized model of a new pleasure car, "The Oriole," which is entirely successful; it will be manufactured by the Giddings & Lewis Manufacturing Company, of Fond du Lac. Cleveland is a son of C. E. Cleveland, president of the big machinery concern.

With new officers and a thorough housecleaning, the reorganized Berkshire Auto Car Company of Pittsfield, Mass., is entering the field with energy. It is planned to develop the undertaking to its highest point and to widen the market for the product. James Addison is president and treasurer; Stuart Clapp, vice-president, and E. B. Belcher, construction engineer.

The annual meeting and election of the Hartford Rubber Works Mutual Benefit Association resulted as follows: President, C. B. Whittlesey; vice-president, George Holloway; secretary, A. Elmer; treasurer, E. Fothergill. During the past three years there has been paid out in benefits to members $5,000 in cases of sickness and death. The association has a membership of 500.

A consolidation of the Standard Gauge Steel Company and the Standard Connecting Rod Company, of Beaver Falls, Pa., has been effected. The new corporation will be known as the Standard Gauge Steel Company. By the merger facilities will be improved and capacity increased. The full lines made by each of the companies interested will be continued and others under consideration added. The management will be practically the same as it has been in both corporations.

A. L. Riker, chief engineer, Locomobile Company of America



New salesroom of the Cook & Stoddard Company, at Washington, D. C., dealers in Pierce-Arrow cars, opened the first of April

The Vivax Storage Battery Company, 2228 Michigan Boulevard, Chicago, has succeeded to the manufacture of the DurO line of storage batteries for automobile ignition and lighting. W. R. Gibbs, for years the president and general manager of the DurO battery, has decided to make his home in the East.

The New Departure Manufacturing Company, of Bristol, Conn., is making additions to the big plant, which will afford an increase in floor space of 32,000 square feet. The foundations have also been laid for additional gas-engine equipment. Gas engines have been used by the company for power purposes for some time with good results.

An addition to the Moon Motor Car Company factory is now being built for the accommodation of the increased number of cars in the testing stage. The test cars, while undergoing their road test preparatory to the 200-mile perfect score run, which each must take before it is sent to the paint shop, will be housed in the new department, to be known as the test-car garage. The garage will be large enough to accommodate thirty to forty cars. It is being built in the quadrangle formed by the three wings of the big plant and a high fence topped with barbed wire. The new department will be ready for occupancy in April.

Among the Various Agencies

F. T. Reed has taken the Hartford agency for the National.

The Pierce-Arrow has been taken on by the Savannah Motor Car Company.

W. B. Worley, of Jacksonville, Fla., has secured the State agency for the Hupmobile.

The Republic Tire Agency in Buffalo has moved from 46 West Chippewa street to 908 Main street.

A Boston agency for Rauch & Lang electrics has been opened by H. C. & C. D. Castle, who handle the Lozier car.

The Savannah Taxicab Company has been appointed representative for the "Empire 20" and the "Page-Detroit."

McPherson & Waterbury, Plattsburg, N. Y., manager of the New Garage, have been given the agency for the Cole "30."

Hugh Miller has taken the agency in Cleveland for the Palmer & Singer line and opened headquarters at 6506 Euclid avenue.

O. S. Johnson has been appointed to succeed R. H. Gillis as manager of the Buffalo agency of the Hartford Rubber Works Company.

The Alden Sampson Manufacturing Company announces the removal of its sales office to 102 West Forty-sixth street, New York.

John W. Frey has opened a store at 698-700 Main street, Buffalo, with a complete line of supplies for motor cars, motorcycles and motor boats.

S. R. Bailey & Company, Amesbury, Mass., manufacturers of the Bailey electric car, opened a branch at 1024 Boylston street, Boston, Mass.

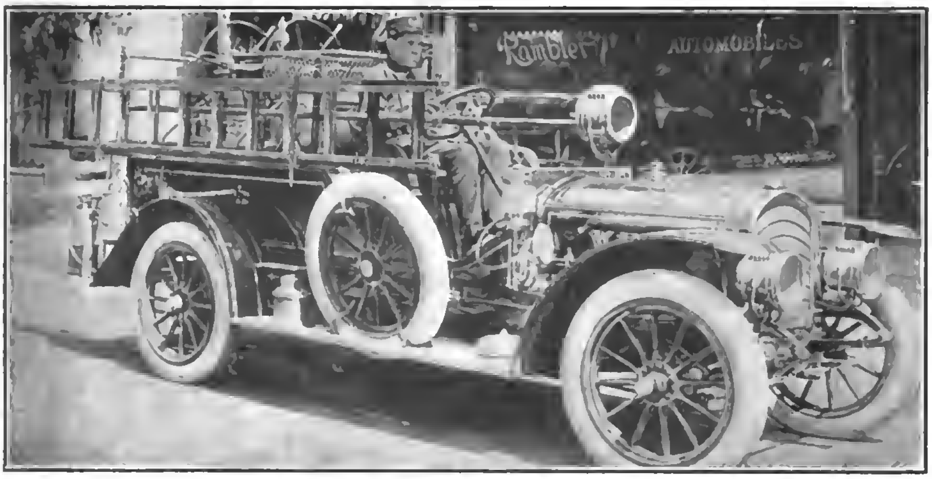
Joseph H. Greenwald, Cleveland agent for Harmon and Moon cars, has just occupied new and larger quarters at 6504 Euclid avenue, Cleveland.

The Foss-Hughes Motor Car Company, agent in Baltimore for the Pierce-Arrow, moved to handsome new quarters, 810 North Charles street.

The Locomobile Agency at Savannah has been given to Carter, Logan & Bro. They have taken it on for several states. A carload of them have been received.

The Parkersburg Motor Car Company, manager, William Caskey, is taking over the business formerly conducted by the Mead Motor Company, on Juliana street.

The Cole car is now located at 289 Berkeley street, near Boylston street, in Boston, the G. E. & H. J. Habich Company having leased salesrooms last week.



The use of motor trucks for various purpose s is growing rapidly on the Western coast. New Rambler chemical delivered to city of Whittier, Cal.

Speedwell Automobile Company, of Pittsburgh, formerly at 5986 Centre avenue, has moved to 5922-5924 Bond street, East End, where it has more than doubled the show room.

H. Heller, of Youngstown, has been appointed Empire and Clark agent for that territory. The Vail Motor Sales Company, of Cleveland, made the arrangements last week.

Oakley Bean has secured the Elmore agency for Jefferson, Clearfield, Indiana, Armstrong and Clarion counties, Pennsylvania, and will have his headquarters at Punxsutawney, Pa.

J. H. Greenwald, agent for the Moon and Marmon cars in Cleveland, has moved his line into a new salesroom and garage. The show room is 140 by 35 feet. Their repair department is almost twice as large.

The Major Motor Car Company, of St. Louis, has obtained the agencies for the Pennsylvania car and the Herreshoff car, and has leased the garage at 1512-1514 Locust street. The garage has been thoroughly remodeled.

H. M. Adams, sales manager of the Royal Tourist Car Company, has appointed the American garage, of Indianapolis, agent for the Royal Tourist line in that city. Demonstrating cars have already been shipped.

Thomas M. Brown, Wilmington, Del., has been given the agency for the Cole "30" for New Castle County, and certain selling rights for the State of Delaware and eastern Maryland, by the Colt-Stratton Company, of New York.

G. E. Lutsey has been re-elected president of the New London (Wis.) Automobile Company. All other officers were re-elected at the annual meeting. It was decided to continue the agency for the Buick and do a general motor livery business.

A. M. Llano has secured the agency for the Petrel car in New York and Long Island and will shortly open salesrooms on Broadway. He has sublet the Brooklyn and Long Island agencies to W. Laubendorf and E. Engrlage.

The Martell Motor Car Company, of which Albert A. Martell is manager, has taken the Eastern Massachusetts agency for the Firestone-Columbus, with temporary headquarters at 3368 Washington street, where he has a big garage.

Ford agents of Ohio held a big convention at Youngstown, O., Tuesday. The meeting was presided over by M. D. Coate, Ohio branch manager of the Ford Motor Company. A street parade of one hundred Ford cars was held.

The Langan and Taylor Storage and Moving Company has installed an automobile department at Garrison avenue and Olive street. The company will act as agent for the Ford, Buick, Speedwell, Apperson, Anhut Six, Cartercar, and other makes.

H. D. Van Brunt, manager of the Buffalo Regal Auto Co., has placed the Regal in two new agencies in western New York. The Genesee Motor Vehicle Co. will handle the car in Rochester, and the W. B. Preston Motor Car Company in Lockport. A recent addition to the force of the Buffalo Regal Auto Company is J. S. Hodge, formerly with the manager of the Buffalo agency when the latter was territory superintendent in western New York for the Olds Motor Company.

Doings of the Garage World

Harry Mitchell and others connected with the Tri-State Garage Company at Uniontown, Pa., have bought from Frank Lewellyn, his garage at 76 East Fayette street, and will use it as an addition to their own plant. Mr. Lewellyn had the agency for the E.-M.-F. car.

C. E. Watson, a well-known engineer of the National Tube Co., is preparing to open an automobile garage in the Leppig Building, Walnut street, McKeesport, Pa. He will handle the Overland and Marmon, and will also carry a full line of accessories.

Stoll Brothers, Mount Pulaski, Ill., are erecting a three-story brick building, the first floor to be used as a garage, the second floor as a display and sales room and the third floor as a public hall.

Work on the construction of the addition to the Widaman garage in Warsaw, Ind., has been commenced. The addition will be 50 feet long and 60 feet wide and two stories high. The second floor will be used as a workshop.

The Franklin Automobile Co. has taken a 15-year lease at 1114 and 1116 Race street, Cincinnati. A two-story and basement concrete and fireproof garage is to be ready for occupancy in a short time. The lot is 38 by 110 feet. The lease involves a rental of about $50,000 for the term, including the fixed charges.

The Saurer truck, eastern branch, has closed a lease on a new six-story and basement fireproof building 50 by 100 at 411-413 West Fifty-fifth street, New York. This building will be devoted entirely to shops, stock, storage and garaging. The main office, however, will still remain at 1876 Broadway.

Brief Personal Mention

Fred Kamp, formerly with O. N. Beebe, of Hartford, has accepted a position with Frederick A. Smith & Company, 1777 Broadway, New York.

H. H. Leckler, for sometime past a salesman for the F. B. Stearns Company, at Cleveland, has joined the forces of the Olds-Oakland Company, at Cleveland.

Charles Clifton, of the Pierce-Arrow Motor Company, has been elected first vice-president of the Buffalo Association for the Relief and Control of Tuberculosis.

Harry B. Tuttle, for a long time with the Stoddard-Dayton organization, has accepted a position with the Willys-Overland Company as superintendent of agencies.

F. W. Haines, general manager, Regal Motor Car Company, Detroit

J. H. Wills has been chosen factory manager for the Gaeth Automobile Company, of Cleveland, by George S. Patterson, who recently became general manager of the Gaeth Company.

William S. Duvall has been elected president of the Automobile Club of Washington to succeed H. Chadwick Hunter, who resigned on account of ill health. Mr. Duvall was the first president of the club, which was organized in September, 1905.

Emil Gruenfeldt, chief designer at the plant of the Baker Motor Vehicle Company, has sailed for Europe, where he will spend several months studying foreign methods of automobile construction.

D. P. Thorpe, of Detroit, has associated himself with F. S. Carr Company, of Boston, manufacturers of automobile top materials. He was for many years with H. Scherer & Co., of Detroit.

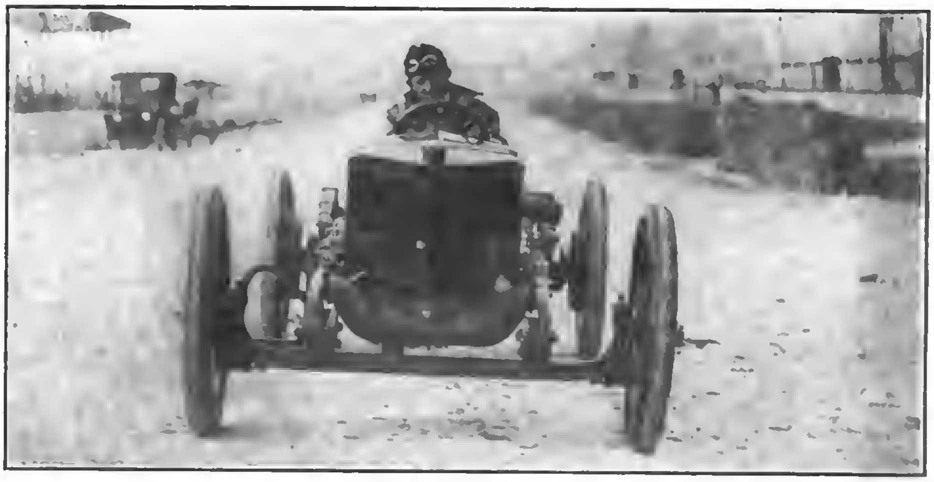
James B. Fiedler, formerly of the Syracuse Buick truck department and later of the Willis Motor Car Company, has accepted a position as traveling salesman for western New York for the Buffalo Regal Auto Company.

C. W. Hatch, well known in the automobile trade as a salesman of accessories and parts and located in Detroit, Mich., for the past few years, has accepted a position as salesman with the Perfection Spring Company.

Alvan T. Fuller, who handles the Packard cars in Boston, is soon to be married, so it is reported in the Hub. His engagement has been announced to Miss Viola Davenport, a well-known singer, who has been studying to become an opera star.

Several notable changes have been effected in the selling forces of the Royal Tourist Car Company, of Cleveland, Ohio. E. D. Shurmer has taken charge of the selling territory, with Chicago as a center, and will in future devote his entire time to the Western districts. A. D. MacLachlin, the former general sales manager of the company, who has been identified with the Chicago end of the Royal Tourist selling forces, takes a traveling sales managership and will confine his attentions to the East with headquarters in New York. Horace B. Hills, Jr., who is the New York representative of the car, has strengthened his sales forces considerably.

C. R. Mabley, manager, American agency, R. I. V. ball bearings



Marmon Yellow Jacket, with wind resistance decreasing body, which has recently proven its utility in automobile racing

News Notes in General

The St. Louis Overland Company has been incorporated to deal in gasoline and electric vehicles. The capital stock is $20,000, of which one-half is paid.

"There would be 5,000 more men employed in Flint in the Buick & Weston-Mott factories if there were enough houses in the city to accommodate them and their families," says C. S. Mott.

Hudson Valley Chauffeurs' Club has been organized at Newburgh with nineteen charter members. The avowed object of the organization is to promote sociability and good-fellowship among the operators.

The A. B. C. Castings Company, of Cleveland, has opened its new foundry at 6515 Carnegie avenue S. E. The plant installed contains the latest equipment and is said to be the largest aluminum foundry in the country under a single roof.

Aldermen of Buffalo have approved the revised ordinances of that city governing public garages. Hereafter it will be necessary to get a permit from the Mayor to conduct such an establishment, and erection of them is made subject to the approval of the Fire Commissioners and Board of Health.

The Holsman Equipment Company has been organized to take care of the repair business of the Holsman Automobile Company, which went into the hands of a receiver last January. The new concern is located in the old Holsman automobile factory, 3600 South Morgan street, Chicago.

D. J. Welton, of Columbus, O., has received a patent on an improvement on the Welton fender, which is manufactured by a Columbus company at Springfield, O. J. W. Howe is general manager of the company. The sale of the fender in Central Ohio is controlled by the Early Motor Car Company.

The Michigan Auto Castings Company will locate a foundry in Pontiac. Ground has been donated by William H. Osmun on Osmun street. Congressman S. W. Smith has wired the promoters that he will subscribe for 5,000 shares of stock. His son, Ferris Smith, has taken 1,000 shares. The capital of the company will be $100,000.

An automobile passenger line, the first of its kind in the Northwest, is to be operated between Minneapolis and Anoka, beginning June 1. The line is to be owned and operated by the Girling Motor Company, which is being incorporated with a capitalization of $25,000. The company has purchased a 16-passenger automobile, which for the first few months will make two trips a day to Anoka and return.

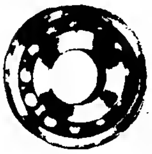
Mayor John F. Fitzgerald, of Boston, and a number of prominent citizens of Boston, Revere, Lynn and Saugus appeared at a hearing before the legislative committee on roads and bridges at Boston last week and advocated the passage of a bill to appropriate $300,000 for the construction of the so-called "missing link" in the North Shore highway from Eliot Circle in the Revere Boulevard to the Lynnway at the Point of Pines bridge.

"Metal Spinning" is the title of bulletin No. 57, from the Industrial Press, 49-55 Lafayette street, New York City. It deals with that ancient art comprehensively, and in view of the scarcity of literature on this subject, not forgetting the importance of metal spinning in the automobile industry, it is a commendable undertaking, and the care with which the material has been prepared is fully up to the customary standard of the publisher. The little work is made up of three articles which were published in "Machinery." The price is 25 cents.

Prominent Automobile Accessories

NEW TWO-POINT BALL BEARING

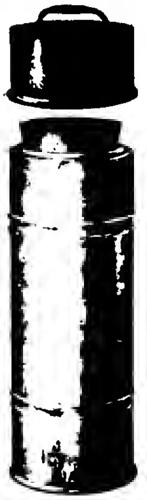
Ten years of experience in the manufacture of ball bearings for automobile use have given the F. F. Cameron Company, Hillsdale, N. H., a sufficient fund of experience from which to evolve not alone a well-made bearing, but a well-designed one as well. The bearing produced, which is illustrated below, is of the two-point type, in which the ball bears on the outer raceways in but two points, and those two opposite one another. The rings are made, both inner and outer, of a special high grade of steel carbonized and hardened so as to give the best results. The balls are of the best imported German make, and are guaranteed to the concern as within 1-1000 in. of being absolutely correct. The high side of the inner and outer races is so made as to make it possible to adjust for wear, thus, also, doing away with the necessity of extra thrust bearings, in situations where the bearing is subjected to an endwise load as well as a radial one. All races are made with very wide sides, this wide side on the races stiffening the same, making it possible to carry a heavier load with any given size of bearing. The bearings are made in all metric and inch sizes. These sizes are interchangeable with the sizes corresponding of other bearings, and the very large stock carried on hand at all times allows quick deliveries.



Cameron Bearing

HEAT RETAINING BOTTLE

Although there are many devices now on the market for retaining the temperature of a liquid just as it is, whether very hot or very cold, for many hours, there is always room for one more. The Icy-Hot bottle, herewith illustrated, is one of these, and now that Summer is coming, with time for long rides into the country, it should be in great demand for carrying the liquid complement to lunches. This form of bottle is made with a vacuum chamber around the central container portion, which vacuum part does not act as a conductor of heat, either from the outside air in or from the inside out. In this way, the dead air space keeps the liquid within at about the same temperature for many hours. Since first brought out, this handy little accessory has met with great favor, and an increasing number of them are sold every year, for just the picnic purpose described above.



Icy-Hot Bottle

PRIZE CUPS TO CLEVER ONES

The Electric Goods Manufacturing Company, of Canton, Mass., is offering fifty $10 prize cups free to motorboat clubs if the clubs will enter into a contest involving "Prefex" Ignition System, in such a way as to bring out the waterproof qualities of same in comparison with the waterproof qualities of ignition systems in general. This offer is to be held open for thirty days. The judge must be the editor of some magazine to be chosen by the competitors.

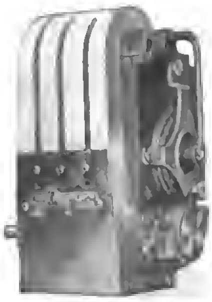
ATWATER-KENT UNISPARKER

Ignition is so puzzling a thing to the average person that any device tending toward simplification of the ignition system, either in part or wholly, is worthy of more than passing mention. In this device, the same result is brought about as in a magneto or combination of batteries and timer, the whole mechanism being very small and decidedly simple in construction. The claims made for it by the makers include first of all the one just mentioned, that of simplicity. Then, it is claimed to be very saving of power, since but one spark is produced at the exactly correct instant, while other ignition systems produce a number of sparks, the waste of current varying with the number produced. The results obtained are such that batteries which ordinarily last but a few months are made to go through a whole season and more. Thus, it is claimed that as high as 3,500 miles has been made off of one small set of ordinary dry cells, which is remarkable, if possible of duplication by the ordinary user.

Atwater Kent Unisparker Complete

K-W HIGH-TENSION MAGNETO

The cause of simplified ignition is furthered by the use of a magneto of such a construction as to permit the ordinary user to make simple repairs and adjustments. Such a one is the K-W, made by the K-W Ignition Company, of Cleveland. The cut shows model H, a four-magnet type, which may be had for four, six, or eight cylinders. The difference between this and other magnetos lies in the windings, both the primary and secondary windings being circular in form and stationary in position, so that the high-tension current is taken directly from the windings and carried to the distributor without the intervention of a commutator and brush.



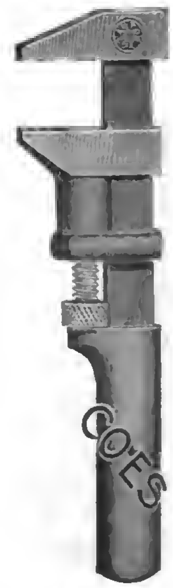
K-W Magneto

FLASH—A POWDERED DECARBONIZER

The Flash Mfg. Co., Zanesville, O., reports that the users of Flash Decarbonizer are pleased with the results obtained. Flash comes in cartons, in dry form, and is designed to remove carbon deposits in gas and gasoline engines. The material when in the cylinders combines with such free carbon as may be present, forms a gas as the product of the combination, which is then expelled with the normal products of combustion.

COES WRENCHES

Any fine tool is worthy of respect, a thing which the ordinary monkey or other wrench seldom gets. The wrenches made by the Coes Wrench Company, Worcester, Mass., are, however, accorded slightly more in this respect than others, for the simple reason that they are very well made, of first-class material, and subject to rigid and numerous inspections.



Coes Wrench

Vol. XXII. New York—Thursday, May 26, 1910—Chicago No. 21

THE AUTOMOBILE

In Lively Run L. I. A. C. Wins From Crescent A. C.

SOLID enjoyment, a sociable run and a fine practical test of the automobile upon the highways of Long Island, were the results of the first annual challenge run of the Long Island Automobile Club and the Crescent Athletic Club of Brooklyn, which was held Saturday and Sunday.

The contest grew out of a bantering challenge on the part of members of the Crescent club, and almost as soon as the challenge had been delivered, the A. R. Pardington cup had been tendered as a perpetual trophy for the winners. Under the conditions as they were finally framed the contest took this form: An equal number of entries (fifteen) from each club should compete. The club that had the least penalization should be declared the winner. Entrants to be active members of either of the clubs. No technical examination at the finish and ability on the road to be the sole criterion of merit.

The affair attracted much interest among the members of both organizations and if the rules had permitted it many more entries than fifteen on a side could have been secured with great ease.

As it was, that number of cars were formally entered and Saturday morning all thirty were sent away from the clubhouse of the L. I. A. C. The course was generally along the South Shore to Blue Point where noon control had been established and where the tourists and a cavalcade of non-contestants enjoyed luncheon. From Blue Point, the way lay to Quogue and Easthampton, where the course turned backward to Riverhead. Saturday night was spent at that place.

The pace was leisurely, the roads were good and the first leg of the tour was accomplished with surprisingly little trouble of any kind. A "stag" party, for which the talent had been imported from New York, enlivened Saturday evening at Riverhead, and Sunday morning the tourists took up the return course.

The first day's run, which covered 132 miles in nine hours, was accomplished by all thirty of the entrants without penalty of any kind for road work. This speaks volumes for the character of the Long Island highways as well for the cars, and as for the care and skill of the various drivers, nothing need be said more than to point out that the result was fitting, and most agreeable.

All Connecticut

TRAVELING about 200 miles a day for three days, over roads that ran the gamut of road making possibility, the cars entered in the All Connecticut Reliability Run, under the auspices of the Automobile Club of Hartford, were given a test that measures up closely in severity with the Glidden tour. The run only occupied three days but if there is anything in the way of running conditions that was overlooked in selecting the routes, the fact did not develop.

The principle upon which the courses were picked out was to afford a journey over roads that would prove the worth of any car that could pass over them. This does not mean that the roads were all bad—far from it, for there were stretches as long as fifty miles en route, that cannot be excellent for smoothness, straightness and general excellence. But on the other hand. part of the route was laid out in the sky-line of the Connecticut hills, over roads that seemed to have been broken through the forest the week before for the purpose of giving the cars a few entirely new wrenches.

The entries numbered twenty-two, but the Tiley and the Pierce-Racine were withdrawn and did not start. The pilot car was a Columbia 6-cylinder automobile, an experimental car driven by its designer Charles E. Reddig. It left Hartford at 4 o'clock each morning, two hours in advance of the regular contestants and distributed confetti along the roads. The others started in two classes, commencing at 6 o'clock and 6.30 respectively. The two divisions listed at the smaller figures started first and the more highly priced cars closed the procession.

The first day's trip was about as trying to cars and drivers as it is possible for human ingenuity to devise. There were grand stretches of highway here and there. but up in the northwestern corner of the State the hills and the mud and broken roads gave the cars a terrific trial.

The two Cartercars were the first to succumb, as their gasoline tanks were emptied before noon control at Torrington was reached. Neither of the staunch little machines had developed any structural or mechanical troubles and as soon as the beneficent Standard Oil tank wagon hove in sight, they both put on speed and checked in after the other cars.

From Torrington the roads were superlatively fierce clear past New Milford, but from that point they were generally good to Hartford. Nine cars finished the day with clean road scores.

The first day covered the Northwestern part of the State in a big loop that extended nearly to the New York and Massachusetts lines and was 207.8 miles.

The second day's run was over some of

Reliability Run

the best and a little of the worst going in the State. It went Southwestward through Danbury and Norwalk, touched Bridgeport at noon control and trended back to Hartford by the way of New Haven, Old Saybrook and the Connecticut River road. The finest bits of this route were the Berlin pike, a remarkable highway in a dozen different ways, and a bit of impromptu mountain climbing between Waterbury and the Housatonic River.

Four of the cars that had perfect road scores the first day were penalized during this run and the terrific racking the cars received the first day began to show on the surface in a few instances. But all told, the day was far better in the matter of scores than the preceding day had been for eleven cars received no black marks. The Corbin entry and the Reo suffered most, the first with carbureter troubles and the other with one of its pet cocks.

The third day's course was over the eastern part of the State, passing through New London and Woodstock to Willimantic where noon control was welcomed after 120 miles of exceedingly difficult going. From Willimantic the route was Northwestward to Thompsonville and thence to Hartford, a total of 191.4 miles.

Of the cars that had clean road scores during the first two days, the Franklin No. 3 was the only one to be penalized for road work on the final day's run. The Columbia 16; Auburn 14; Franklin 10 and the Lexington coming through the whole tour without a mark against them for road work.

The technical examination brought out many penalties as the examination was particularly severe. The clutch and brake tests broke several perfect scores and the final measurements and tests added materially to the list of penalization.

The Columbia entry in Division 5A had a clean score on the road and scored perfect in the final tests. The Franklin Number 10 in Division 6A was perfect in road work but was penalized a single point by the technical committee, while the Speedwell 15 and the National 8 only suffered 3 and 4 points respectively for their road work and scored perfect under the technical tests. Both were in Division 5A. The showing of the Regal Number 4 was creditable with only 13 points charged against it. Ten of these were for troubles on the road that had no bearing on mechanical or structural weakness and the other three were levied by the technical committee as appears in detail in the following table.

The whole affair was conducted with professional accuracy and the official comment upon the result was that any car that was able to make a good score in the event, was a "sure-enough automobile."

Norristown

NORRISTOWN, PA., May 23—After 48 hours work on the 23 cars which were submitted to them at the finish of the Third Annual Endurance Run to Scranton and return, the Technical Committee of the Norristown Automobile Club early this evening announced the Selden, No. 23, driven by Charles Youngs, as the winner in Class A with a penalization of 38 points; Maxwell No. 9, Harry E. Walls, driver, the class B winner with 26 points; Pullman, No. 19, with H. P. Hardesty at the wheel, the successful one in Class C, with 49 points; and the Kline-Kar, No. 30, driven by C. C. Fairlamb, the leader in the race for Class D honors, with 70 demerits to its credit.

In the membership division, Selden, No. 34, Fred Dyer, driver, was awarded first honors. This class was not required to undergo a technical examination.

The run was an especially severe test, as may be gathered from the statement that on the first day 25 of the 36 cars that were classed as contestants were penalized, most of the demerits being due to lateness at controls, or to mechanical defects developed by the hard usage to which the drivers necessarily subjected their cars in the effort to adhere to the schedule. The 20-miles-an-hour schedule was particularly severe on the Class D cars ($1,600 and under runabouts), all of the nine contestants suffering penalization. The road conditions on the first day were generally bad, an intermittent rain falling throughout the day, which, with a steady downpour during the previous night, rendered the roads, especially in the mountains, decidedly unsafe for a 20-mile schedule. This fact was borne in upon the committee at the last intermediate control of the day (Wilkes-Barre) an hour and ten minutes being allowed for the 18.6 mile leg, and the reduction was needed, for the roads between the two cities were frightful. Low and intermediate gear was necessary on a large proportion of the Pottsville-Hazleton, and the Hazleton-Wilkes-Barre legs, and when a good stretch of road was encountered it was usually so slippery that great care was necessary in negotiating it. When the fine State road leading over the mountains from Fairview to Wilkes-Barre was reached, the contestants went in for speed in order to make up the time they had lost, and several nasty accidents were narrowly averted. Palmer-Singer, No. 16, George Parker, driver, was crowded to the outside while passing another car on a sharp curve, and swung into the iron fence protecting the road; it hung for a while over a 90-foot ravine until the crew could get it back on the road; that little incident cost the car 117 road points, all told, not to mention a large proportion of the 59 de-

Reliability Run

merits imposed by the Technical Committee. Inter-State, No. 6, driven by D. F. Templeton, was also a heavy sufferer on the first day, garnering 52 bad marks from a skid into a wagon near Reading. Black Crow, No. 29, tore off its right rear fender in a peculiar manner. A tire chain broke and wrapped around the fender support, breaking it and tearing away the fender. The time lost as a result was so great that the car was later withdrawn, but continued to the finish, unofficially.

Despite the bad roads, disagreeable weather and the severe trial given as a result of the combination, the road work scores were fair.

The conditions on the second day were just the reverse of those on the first. Clear, warm, sunny weather, and good roads. The beauties of the Norristown scheme of prohibiting a car from laying up in control, or on the road between controls, for a longer period than ten minutes, under a penalty of a point for each minute in excess of ten, were demonstrated to the satisfaction of everybody. There was no racing, no crowding at controls, and the checkers' cards, in most instances, were in excellent shape, owing to the fact that they were not rushed by cars bunching up on them. The results demonstrated the wisdom of the A.A.A. in deciding to allow the promoters to retain this important feature of their rules.

While, apart from the stiff schedule, there were few complaints from contestants for the imposition of such liberal penalties on the road, the same cannot be said of the aftermath of the brake and clutch tests, and the technical examination, especially of the former. There does seem to be a flaw somewhere in the A.A.A. table of penalties, when a car which finishes a gruelling two days' run with an absolutely clean road score, without the necessity of touching a tool, even for tire repair, can be penalized the equivalent of a broken pinion or broken torsion rod, when with wheels locked, it slides 25 or 30 feet over the line, as did some of the clean score cars last Friday. An examination of the penalty table shows that fully 50 per cent of the total demerits were imposed during the brake and clutch test.

Every car submitted to the Technical Committee for examination suffered more or less severely, as was to have been expected, under the conditions. Franklin, No. 13, with 7 points, passed the best examination, followed by the Inter-State, No. 6, with 10; Kline-Kar, No. 20, and Buick No. 11, with 12; Kline-Kar, No. 4, with 16, and Enger, No. 7, with 18. All the remainder were over the 30 mark, with the exception of Walls' winning Maxwell, in Class B, which escaped with 25.

A Bit of Interesting Scenery
Trying to Make a Good Score

Blue Ridge Mountain Trek of Much Interest

By HOWARD A. BANKS

A LITTLE independent railroad in the Carolinas, the Carolina & Northwestern, which runs Northwestward from Chester, S. C., to Edgemont, N. C., has furnished evidence to the country that the Blue Ridge Mountains beyond it are accessible to the automobile. Eighteen machines, big and little, went over 100 miles of good auto roads in one of the prettiest resort sections east of the Mississippi, but which has been considered too far away from railroad facilities for the owners of auto cars to visit. The outing, which lasted five days, from May 12 to 16, was planned by Capt. L. T. Nichols, general manager of the C. & N. W. R. R., and it worked out perfectly. Capt. Nichols sent out invitations to some 35 owners of automobiles to go on this trip, each to bring his lady, but seats were also reserved for newspaper men and a few railroad men. The trekers numbered 70 in all.

The automobiles and the members of the party were hauled free of charge over the C. & N. W. R. R. from the point where they reached the railroad, except as to hotel accommodations. A special freight train carried the machines to Edgemont, the starting point for the mountains. The big cars were run aboard on grooved skids, and three expert mechanicians went along and took care of the horseless carriages as mothers would take care of their babes. The only box car contained pieces of machinery, such as might be needed in a breakdown. The freight train unloaded its cargo on the afternoon of May 11, and on Thursday, the 12th, the start was made from the hotel at Edgemont.

Among the automobiles there were four E-M-F's, a Ford, two White Steamers, two Metz, a Hupmobile, two Reo cars, an Elmore, a Maxwell "30," and two high-wheelers of the International Harvester Company make.

The high-wheelers were put first, in order to prevent any daring chauffeur from going too fast, and they set the pace of the remaining machines. The run to Linville from Edgemont is 18 miles, and the first car, leaving at 3.30, got in at 7 o'clock. The ascent is from 1500 to 3800 ft. The engineer of the road was one of the party. The first half of the road, when it was built two or three years ago, was not intended for an automobile road. Some of the curves were a bit sharp, but the drivers rarely had to stop and back after they had learned the contour of the highway. For the first three miles the maximum grade is 6 per cent. After leaving Cary's Flats, about half way, the maximum grade is 5½ per cent.

One of the automobile experts on the tour said that the grades were without objection, and that on them the cars could make from 10 to 15 miles an hour. The roads were in splendid condition. There was a threatening, "spitting" rain when the party left Edgemont, but the procession climbed above the clouds, and the sun shone for the rest of the trip. At the top of the ridge, shortly before the sharp down-drop into Linville, the road was a little heavy, and it was learned that there had been a heavy rain there in the early morning.

An incident which interested the machine owners developed when the cars mounted into an altitude of about 3000 to 3500 feet. The automobiles began to have carbureter trouble. While the merry party raved over the scenic beauty on every side, or ran down the mountainside to pluck some brilliantly colored wildflower, the chauffeur was opening his air gate. A

Old Man Holtzclaw Takes The Toll

The Start at Edgemont

From Oxomobile to Automobile

A Mountain Grist Mill

few owners who had anticipated this thing at Edgemont, and had changed the mixture, escaped with the least difficulty.

The caravan "dawdled" along, making no effort for a record as to speed. At Cary's Flats a hundred mountaineers had gathered to see the automobile for the first time. The children were pretty, rosy-cheeked, clad in red, blue and other glaring colors. The women, however, were faded. Some of the men carried old muzzle rifles, and the party felt relieved when they said they had been shooting ground squirrels which were playing havoc with their corn. And some of the corn, by the way, on the sheer of the mountainside, looked as if the seed must have been shot in with the same rifles. A white-haired, red-eyed fiddler played "Old Dan Tucker," while another mountaineer danced to the patting of hands.

The occupants of several cars got out, and almost instantly the mountaineers were scrambling in, and the chauffeurs good-naturedly hauled them up and down in front of the country store. At half a dozen other places the same thing occurred, and it was a good stroke of policy to allay prejudice against the automobile and its owner.

The only mishap of the entire trip occurred a little further on. An old machine, four years of age and which had traveled 35,000 miles, stopped still 6 miles this side of Linville. Its transmission had gone wrong. Indeed, it was out of fix before starting, the owner acknowledging that he took a risk in running. Part of its occupants were then loaded on other machines. The two-horse wagon which followed the party picked up the three men who stayed with the car, but it was so cold that they walked into Linville, arriving at 11 o'clock. The dead car was rolled back over the mountains the next day.

The Grandfather, 7000 feet high, is the towering peak of this section, and every now and then, as the cars scudded around a sharp bend, his old-man profile, set upon his upheaving shoulder, would cast a patriarchal benediction upon this bit of wheeling civilization in the heart of the hemlocked wilderness.

Before the gigantic fireplaces at the comfortable Esceola Inn at Linville the party "shucked" their wraps and overcoats, and in the dining room dulled appetites which the keen mountain air had whetted sharp. Linville is a charming little village of 30 or 40 cottages and homes, and the Inn is modernly appointed.

An entire day was spent here in fishing in the lake and climbing the mountains, and in golfing, as there are splendid links here. The kit of auto tools offered by the Linville Improvement Company for the biggest catch of trout by an owner of a machine was won by J. W. Zimmerman, of Charlotte, and the silver cup for the longest speckled beauty—and it was 14½ inches—by S. R. Clinton, of Clover, S. C.

The start on Saturday morning, the 14th, for Blowing Rock, 22 miles, over the Yonahlossee, "the Trail of the Big Bear," and one of the famous roads of the Blue Ridge, was made at 9 o'clock, and the first cars arrived at "The Rock" about 11.30. All the cars made the trip on high gear, and there was none of the carbureter trouble of the first day. The drivers had learned how to use their mixture, and the machines seemed to have become acclimated. The party reached the mountains in a cold season, and there was ice at Linville the morning of the start.

After a run to Boone, the county seat of Watauga County, and named for the great pioneer who once lived there, and whose trail up the Yadkin River and its little tributaries is still pointed out, the party began to disintegrate. By Sunday afternoon they had gone, part through the country and the rest taking the special at Lenoir, below Edgemont, on Monday morning. The run to Lenoir from Blowing Rock, 22 miles, completed the last link in a novel and enjoyable outing. The worst mishaps were two hroken springs, which might have occurred just as easily in the low country.

Questions That Arise

A series of practical questions relating to the automobile, its parts, and their functions, which arise upon various occasions, together with easily understood answers to the same.

[23]—What is the nature of the mechanical contrivance which forces a valve to open?

A torsional moment is applied to a shaft; the shaft is provided with a cam; the cam rotates with the shaft; a roller or its equivalent, in line with, and pressing on the cam, is raised by the eccentricity of the cam as it rotates; guides suitably placed, compel the lift, upon the end of which the roller is placed, to press against the end of the valve stem and the pressure thus exerted compels the valve to open. The force is that due to the use of the wedge principle.

[24]—What is the force of the mechanical contrivance which forces the valve to close?

Gravitational force (if the valve is free to fall)to a slight extent only; the force of a spring for the most part.

[25]—Does the cam-action help in the closing of the valve?

No. The cams used in automobile motor construction are of the single acting type; they press in one direction only.

[26]—Why is it that mechanics have not used the positive action of a cam-motion to close the valve as well as to open it?

Considering poppet valves; remembering that they must press against the seat with a certain definite pressure in pounds per square inch, it follows that a certain precision must be taken advantage of, and, from experience, it is gleaned that lost motion and deflections would thwart any such an attempt.

[27]—Why does a spring eliminate trouble of this sort?

The spring continues to press after the valve is seated.

[28]—Why is it not possible to accomplish this same result positively without having to use a spring?

Because the parts, considering a positive link and lever system, or a straight line motion, as usually employed, would have to be stretched (elongated) after contact with the seat; this would tend to disrupt the members, and, since the valves have to be ground in after they become leaky, it is evident that they would no longer respond to the conditions as originally set. An adjustment would have to be provided, and the accuracy demanded is far beyond the skill of workmen.

[29]—Is there any form of valve motion that is free from the spring closing feature?

Most forms of sliding and rotating valves.

[30]—Why are they not used in place of the poppet valve?

They are in certain types of motors, among which are the Knight, and others.

[31]—What are the main points to consider in connection with the various types of motors?

In a general way, the situation may be summed up as follows:

(a) The desired power must be available at the respective speeds.

(b) The weight of the motor must be within allowable limits.

(c) The power must be obtained in such a way as to afford the requisite measure of flexibility.

(d) The fuel consumption must be for the best thermal efficiency.

(e) The motors must be simple and easy to run and maintain.

[32]—Do rotary valves serve more efficaciously than the poppet valve type of motor?

The comparison is without force; each principle, when properly applied, works to advantage. The following are tests of both the poppet and the Knight type of motor.

MEAN EFFECTIVE PRESSURES
(Disregarding Mechanical Losses)

Make	Cylinders	H.P.	R.P.M	M.E.P.
Daimler	Four 124x130mm.	58.0	1,172	106.8
National	Four 5x5 11-16 in.	64.0	1,400	81.1
National	Four 5x5 11-16 in.	54.1	1,055	90.9

Pierce	Six 4x4¾ in.	30.9	800	85.4
Rambler	Four 5x5½ in.	43.5	1,091	73.1
Rambler	Four 5x5½ in.	40.0	900	81.3
Rambler	Four 4½x4½ in.	34.0	1,333	72.2
Rambler	Four 4½x4½ in.	29.0	900	89.2
Thomas	Six 4¼x5½ in.	49.0	1,091	76.0
Thomas	Six 4¼x5½ in.	34.5	700	83.4

[33]—Is it so difficult to design and construct a motor that trouble should be a normal expectation from a large percentage of all the motors designed?

Not necessarily. It is not always possible to convince capital that the difficulties involved are beyond the reach of a man who has the inventive faculty and no skill. In the absence of skill the mere ability of thinking along original lines counts for very little; after action may lead to poor result.

[34]—What is the difference between the inventive faculty and mechanical skill?

An inventive mind is free from the harness which guides the man of skill, borne of experience. The inventor is not afraid of getting into a tangle because he has confidence in his ability to get out again. The inventor is scarcely likely to count the cost—it costs money to get into trouble and more money to get out again. The skilled mechanic, like the judge on the bench, looks up all the precedents before he goes ahead; if the precedents are against him, it is highly improbable that he will take that course. The judicial mechanic, if he is unable to see his way clear to a successful termination of an undertaking, will investigate all phases of the problem, and only advance the work when he is cognizant of a complete solution of the problem; motors that work are the product of the skill of the judicial mechanic.

[35]—Can an inventor violate a principle in the process of designing a motor and not have to pay heavily for thus going contrary to the controlling wind, as it were?

If the inventor can get around Newton's laws, and all the other fixed principles known to mechanics, he may then violate every principle known to mechanics with impunity. No inventor ever yet succeeded in getting away from paying a fine in just proportion to the extent of each violation of every principle involved. and, in the final sum-up, it is more than likely that perfected automobile motors will be those which are in the fullest accord with all the principles known to mechanics, so worked out that they will be in harmony with the exigencies of service, without losing sight of the objective.

[36]—Is not this line of reasoning a little unjust to the inventor, and is it not a little farfetched from the point of view of the discussion of motor problems?

No. In the first place, the inventor of popular conception is not the inventor in fact. The popular view is that an inventor is a man who thinks of a novel way of accomplishing a task; he does not have to know that some other man may have thought of it before him; it is only necessary for him to be ignorant of the working of the other man's brain. There is no question of skill involved—it is a mere thinking process. As a matter of law, and of reasonable fact, an inventor is a man who puts a new and novel idea into practical use, or tells of a way by which anyone skilled in the art may apply the knowledge gained and bring it to a point of practicability. A patent on a device that will not operate, is invalid; merely thinking up a scheme is not an invention; skill and action must be included ere the invention is consummated.

An invention is not operative if it violates some of nature's inscrutable laws; a man who gets so far that he is in violation of these laws, is far from the platform which holds the inventor who is protected by law, and, from what has been said, although it is but an inkling of the whole situation, it is enough to indicate that inventors of popular conception are not slandered when it is told that they make it possible for purchasers of motors to buy both good and bad.

That discussion, such as this, is necessary to the progress which it is desired to make, is avowed, and this contention is proven by the many questions which are asked daily, in which it is desired to know which of two types of motors is the one that should survive. The great main question is entirely overlooked; no thought is given to the controlling factors as follows:

(a) The objective, i. e., the service the motor is intended to render; (b) whether or not the design is free from incongruities; (c) are all the laws of mechanics and of a physical character, properly incorporated, if they are involved? (d) are the parts, considering the character of the materials selected, so designed that they will not be over-fatigued in service? (e) is there a sufficient margin of safety to render the life of the parts in service in keeping with the value of the investment? (f) is the workmanship up to a fitting standard? (g) does the condition expressed in standardization of parts obtain? (h) are the parts insured to the extent of being inspected and tested to be able to know that there is no hidden fault or mistake? (i) how about a final test of the completed motor? (j) is the motor properly related to the automobile so that it will not be cramped in service?

[37]—How will a purchaser know about all these matters?

There is only one sure way; make an examination.

[38]—How can a purchaser do all these things if he is unskilled?

He cannot.

[39]—Under such circumstances what is a purchaser to do?

Display a fair measure of horse sense, and the same acumen that enables him to survive in Wall street and get away without being damaged.

[40]—What is the object in having a differential gear in conjunction with a live rear axle, or in the jack shaft of a side chain-drive type of automobile?

When the torque (twisting moment) of a motor is transmitted to the road wheels, either by means of sprockets and chains, or by a more direct way, as in shaft-driven mechanisms, involving the use of live rear axles, the road wheels are caused to revolve, and, since the two wheels are of the same diameter, they will roll along the ground an equal number of feet per revolution. If the two road wheels are rigidly related to each other, that is to say, if no differential gear system is employed, the automobile will travel in a straight line, unless one of the wheels slips.

It is not desirable to allow one of the wheels to slip every time the automobile is required to turn in a circular path, as when going around a corner, and the differential gear system is introduced to bring about the desired condition. It is the property of a differential system to transmit torque to the two road wheels of the automobile in proportion to their respective tractive conditions, irrespective of the relations of speed, so that in making a curve, as when turning around a corner, the inner wheel may rotate slower than the outer wheel, in proportion to the natural demand, but both wheels will be driving the automobile, nor will there be any slipping of the wheels, despite the fact that one must rotate slower than the other.

[41]—Just why must one of the road wheels travel faster than the other when an automobile is going around a corner?

The two road wheels (referring to the wheels that drive) are of the same diameter, say, 36 inches. The circumference of the wheels then will be:

$$\text{Circumference} = \frac{3.1416 \times \text{diameter in inches}}{12} = \text{feet}$$

$$\frac{3.1416 \times 36}{12} = 9.4248 \text{ feet.}$$

If there is to be no slipping of the wheels it follows that each wheel must roll on the roadbed for a distance of 9.42 feet per revolution, and, since the arc of the circle, which each wheel must describe, is to a different radius, as shown in the figure, the number of revolutions of the two wheels will not be the same, having in mind the fact that there is to be no slipping of either wheel. As the figure shows, considering the difference in the radii $R1$ and $R2$, from the axes OA and OB respectively, of the inner and outer wheels, some device must be used which will permit the two wheels to roll on the ground at different speeds—the differential gear system is devised for just this purpose. The difference in radius between $R1$ and $R2$ is not great in view of the fact that the distance in feet from E to C, as compared to the distance in feet from F to D, of the inner and outer arcs respectively, considering a 90-degree angular relation for both, is proportional to the respective radii.

If the radius of the circle $R1$ is assumed to be 100 feet, the radius of the circle $R2$ will be 100 feet plus the "tread" of the two wheels. If the tread is, say, 5 feet (common practice for cars which are used in the Southern States) the radius $R2$ will then be 105 feet. Considering an arc of 90 degrees, then:

$$EC = \frac{2\pi R1}{4} = \frac{2 \times 3.1416 \times 100}{4} = 157.08 \text{ feet;}$$

and

$$FD = \frac{2\pi R2}{4} = \frac{2 \times 3.1416 \times 105}{4} = 164.93 \text{ feet.}$$

Difference:

$$FD - EC = 164.93 - 157.08 = 7.85 \text{ feet.}$$

The inner wheel would either have to roll independently of the outer wheel, or slip for a distance equal to nearly one - third of its circumference; the difference in the described arc being 7.85 feet and one-third of the circumference of a wheel being in scraping contact with the road in turning. Tire depreciation is involved in this situation, and for the best result it is necessary to use the differential gear.

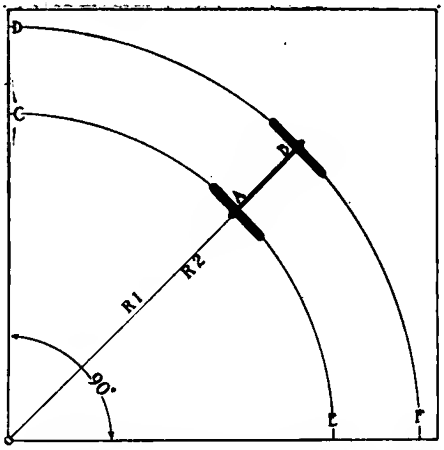

Diagram showing the difference in radius between the inner and outer wheel on a curve.

Engineering Digest

A carefully abstracted digest of accounts of engineering activities as they are reported in society transactions and technical papers throughout the world.

AN **account of the laboratory test** of five kerosene motors in public competition held by a marine association is **presented by Georges Lumet**, chief engineer at the laboratory of the Automobile Club of France. The five motors, of which one is made in Denmark, one in America, and three in France, are described in detail, their main features being as follows:

Dan motor, 4 cylinders, 4-cycle, bore 290 milimeters, stroke 250 millimeters; speed 350 revolutions per minute. The motor is fed by injection of cold liquid kerosene into a cast-iron chamber forming an addition to the combustion chamber and previously brought to a dull red heat. The injection takes place during the fourth cycle (exhaust) of the motor. The kerosene injected into the heated chamber is vaporized on coming in contact with the hot walls. The inlet valves then open to allow pure air to enter the cylinders, where it is mixed with the kerosene vapor. There is no carbureter. The quantity of air aspired is always the same. The amount of kerosene varies with the stroke of the pump. The kerosene nozzles are water cooled.

Aster motor, 4 cylinders, 4-cycle, 160 millimeters, 200 millimeters stroke; speed 550 revolutions a minute, valves on opposite sides. A special Aster carbureter is employed, consisting of a float chamber, a heating chamber obtaining its heat from the exhaust gases, and a variable feed jet. On leaving the jet the heated kerosene is directed against a heated wall, where it is completely pulverized and receives its necessary supply of air through an automobile valve. Ignition is by low-tension magneto contained within a bronze water-tight housing, and make and break. For starting, the carbureter is first heated by a kerosene lamp. Lubrication is by force feed to the main bearings and by splash to the cylinder walls and connecting rod ends, with divisions to retain the oil whatever the inclination of the motor.

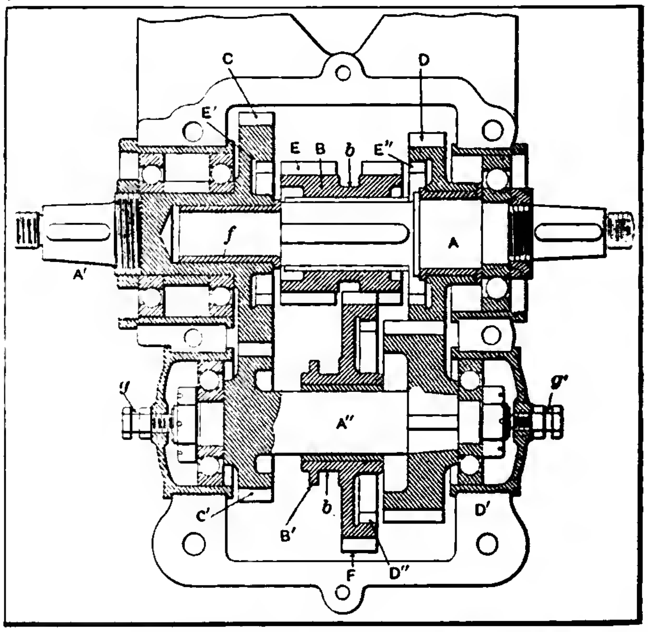
Mietz & Weiss motor, 3-cylinder, 2-cycle motor without valves and without mecanical ignition. Bore 203.2 millimeters, stroke 203.2 millimeters; speed 450 revolutions. The cylinders of the motor compress pure air, and on the maximum of compression being attained kerosene is injected by means of a pump operated from the crankshaft. Ignition is by hot tube.

Peugeot-Tony-Hubert motor, 4 cylinders, 4-cycle, 150 millimeters bore, 190 millimeters stroke; speed 550 revolutions. The cylinders are separate and vertical, with mechanical valves on opposite sides. The motor is fed by two separate Longuemare carbureters heated from the exhaust. Ignition is by high-tension magneto and sparking plugs, or by low-tension magneto and make and break. The carbureters are warmed by means of a lamp to allow of starting; the motor is also designed to receive a compressed-air self-starter. Lubrication is by forced feed through a hollow crankshaft.

Sabathe motor, 3 cylinders, 4-cycle, 220 millimeters bore and and stroke: speed 350 revolutions. On the first stroke the piston aspires pure air; on the second stroke the air is compressed to 60 to 66 pounds per square centimeter, and at the end of this stroke kerosene is admitted. During a portion of the third stroke the admission of kerosent is continued, thus maintaining a constant pressure during a portion of the power stroke. On the fourth stroke the exhaust gases are driven out through mechanically operated valves. Starting is obtained by means of a compressor delivering air at a pressure of 130 pounds per square centimeter.

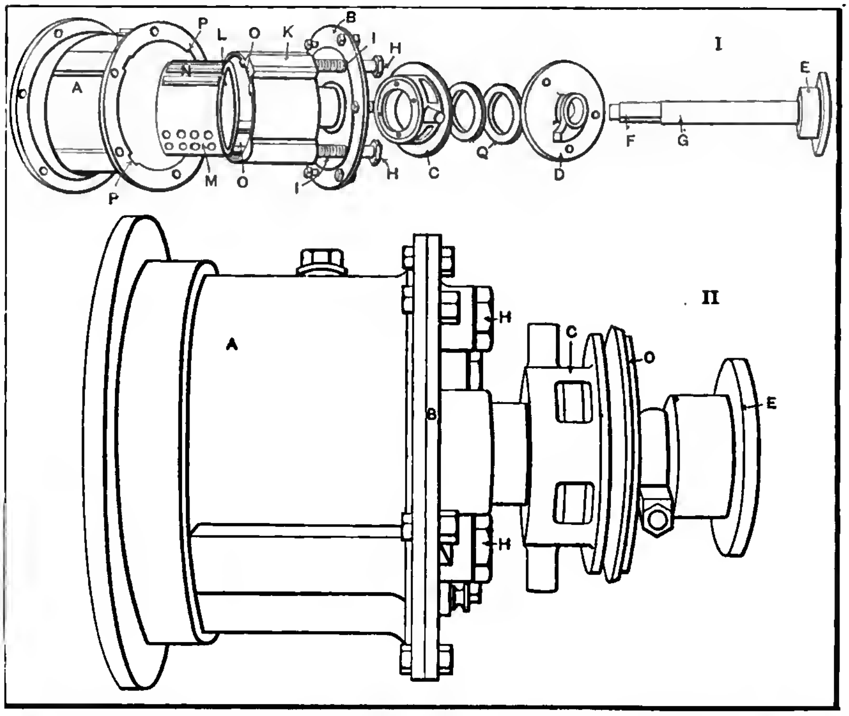
The article is accompanied by a complete table of the results obtained on four tests, two of them being at full power, one at half the normal speed of the motor, and the fourth without load. *Bulletin Officiel de la Commission Technique, Automobile Club de France,* Paris, March number.

Compact Transmission Gear.—Very short shafts supporting their working loads close to their bearings, pinions always in mesh, engagement by internal jaw clutch teeth, direct drive on the third speed, are the characteristic features of this compact transmission gear called the Pujos, the operation of which is readily deciphered from the accompanying drawing. *A* is the primary shaft, *A'* the secondary, *A"* the intermediate. *B* is the first sliding gear pinion, splined on the primary shaft. *B'* is the second sliding pinion, idle on the secondary shaft, and *bb'* are the shifting fork grooves. *C* and *C'* are the constant mesh pinions connecting the secondary and the intermediate shafts. *D* is the idle pinion of the second speed, *D'* the splined pinion of the second speed and *D"* the clutch pinion of the low speed. *E* is the splined pinion of the low speed, and *E'* the clutch pinion of the direct drive, while *E"* is the clutch pinion of the second speed. *F* is the idle pinion of the low speed, *f* the bearing sleeve between the first and secondary shafts and *gg'* screws and nuts for adjusting the intermediate shaft longitudinally.—*Omnia*, April 23.



Section of the Pujos Transmission Gear showing Compactness and Stability by taking Advantage of Short Distances between Ball Bearings of Annular Type, taper methods of fastening Universal Joints to the Stub Ends of the Shafts and other up-to-date Refinements

Small Metallic Conical Clutch.—The cast-iron clutch drum *A* is secured to the flywheel. The shaft of the transmission is secured by collar *E* to shaft *G*, the end of which is squared, and on the squared end is mounted the small drum *L*, which is held between two elastic half-collars lined with bronze bushings, or friction shoes *M*. Each of the half-collars is provided with two conical "gads" *N*. The sliding member *K* has two internal V-shaped grooves tapering at the same angle as the conical gads. When this sliding member is advanced, it pushes the conical gads against one another and thereby grips the drum *L* with the half-collars *M*. If, on the other hand, the sliding member is withdrawn, the gads become free to separate, the collars are released and the vehicle is unclutched, in which action centrifugality assists. The sliding member *K* becomes united with the cylindrical clutch drum *A* by means of splines and grooves. The ball-bearing collar *C* serves to disengage the mechanism and abuts against the clutch brake *D*, which is faced with leather, this permitting quick retardation of the drum *L*. The customary clutch spring encircling the shaft is replaced by four small springs *I* which are adjusted by the screws *H* in such manner that, when the springs are completely relaxed and extended, their rear ends engage slightly with holes sunk for this purpose in the clutch box cover *B*, the idea being that when the clutch is dismounted the springs will not fly in the face of the workman or get lost. The mounting and dismounting of the mechanism are particularly simple. Changes in the consistency of the oil in which it runs do not affect the operation, and repairs would be inexpensive.—*Omnia*, April 23.



Small metallic conical Clutch and Parts of same, which is interesting because of its Rugged Simplicity

An analysis of the gains and losses due to the offsetting of crankshafts in motors is begun by v. Doblhoff in *Der Motorwagen* for April 30. The treatment is mathematical and graphical. Weighing all the factors against each other, the author arrives at the conclusion that the advantages of offsetting reach their net maximum when the offset of the crankshaft axis is about one-half of the crankarm length, as in the Brasier motor. Offset affects: (1) piston travel, (2) the angular velocities of connecting rod and crankarm and (3) the piston accelerations, and thereby causes changes in (1) the cycle, (2) the frictions, (3) the variations of torque, (4) the balancing of the masses and (5) the turning moment on motor and shaft. As piston travel increases with offsetting, if the crankarm length remains unchanged, and the author wishes to compare conditions which are essentially alike, he assumes the piston travel to be constant and takes the crankarm length as the variable of these two. Formulas are derived from diagram for the crankarm length and for the location of the dead centers. With a view to a subsequent calculation of the frictions, he arrives at formulated values for the piston speed, the speed of the crankpin and of the connecting rod, using the tri-polar thesis relating to the movements in one plane of three co-ordinated points, according to which the poles of the three movements fall into a straight line and the velocity of each of the three points may be considered as a function of the velocities of the two other points. The values of piston acceleration are shown constructively by diagram. While it is often claimed as an advantage for offset construction that it affords more time for the expansion of the gases of the explosion, at equal revolutions per minute, due consideration of the difference in the angles described by the crankpin for the downstroke and for the upstroke shows that an offset, even as great as one-half of the piston stroke, produces a difference of only 6 degrees in these angles, and this difference represents only 4 per cent. of the time available for the expansion of gases in a straight-stroke motor, and it is not plausible to assume that the cycle of forces would be greatly influenced by this difference. Under frictions, the author considers piston friction, piston pin friction, crankpin friction and the friction on the shaft bearings, while noting that certain elements of the friction, due to the viscosity of lubricating oil and to the expansion pressure of piston rings, are independent of the lateral pressures transmitted to cylinder walls and elsewhere through the connecting rod, and therefore need not be considered when the question is that of calculating the effect of offset. The frictions are calculated, as "work," from the three factors, pressures, coefficients and velocities, while the weight of the parts is considered negligible in the case of automobile motors. The treatise is yet to be concluded.

Pumping Losses Interfere with the Process

What are pumping losses? They are all the losses which have to be coped with when a motor is put into motion. They detract from the force of the power stroke. Were there no pumping losses, the motor, were it to be put into motion, would keep on running forever, or, until it assumes the form of a mechanical wreck.

If the pumping losses are very great in proportion, it is then that the motor would start on the spark, so called, with great difficulty, or to put it in language more in keeping, with far less certainty. The pumping losses increase with the speed, but they are sufficient in poorly made motors to defeat starting on the spark, so called, owing to the feebleness of the force which it is possible to realize when the compression is limited to that which comes from boiling gasoline in the presence of enough air to provide the oxygen to produce a burning mixture, excepting in a motor's cylinder. Likewise, in a motor which is well made, even assuming that all the parts are so nicely fitted that friction is reduced to a very low point, if the cold compression is high, as it will be, that is to say, the compression which will come as soon as the motor begins to rotate, due to the fact that one piston will make its compression stroke, while another is on the power stroke, the power required to equal the force of the generating compression will be greater than the power which can be wrung out of a feeble explosion.

Cleaning Leather Cushions

Editor THE AUTOMOBILE:

[2,271]—In one of your issues of the magazine lately, you have a notice of the best method of treating the leather cushions to cleanse them and make them look better. A. B. WARFIELD.

Woonsocket, R. I.

We are unable to find the article referred to anywhere back to the first of the year, and issues beyond that would hardly classify as "recent." In the issues since then nothing of this sort has been published. As a matter of fact, the cleaning and treatment are very simple. A weak acid may be used to clean off foreign matter, following which the leather should have a very thorough cleansing with warm water to remove every possible trace of the acid. The leather is then softened with castor oil, or, better, neatsfoot oil, which may be obtained from any dealer in leather, or from nearly all paint stores. It is a good idea to have this oil around and apply it at all times, for it makes the leather softer, more pliable, and much better looking. Moreover, it is useful for all kinds of leather.

Two Versus Four Cylinders

Editor THE AUTOMOBILE:

[2,272]—Is it true that, other things such as power and weight being equal, a two-cylinder car will give better service over rough country roads than a four-cylinder car? Does the former possess any material advantage over the latter for use in heavy sandy roads, because its engine weight is better distributed, when the engine is placed under the frame, than is the case with a four-cylinder engine in the hood? It is claimed that a car with its engine in front will sink deeper into the sand, leaving insufficient weight over the rear axle to prevent the rear wheels from spinning.

Mesilla Park, N. M. FRANCIS E. LESTER.

No; two cylinders will not give better service. However, it is not quite fair to any type of motor to compare it with some other and different design; it is like adding oranges and apples, they are likely to make peaches.

Always Starts on the Spark

Editor THE AUTOMOBILE:

[2,273]—I was much interested in reading Inquiry Number 2,201 in the issue of the 24th inst., but surprised when I read the closing paragraph of your reply in which you said: "It is doubtful if the experiment spoken of, in which the spark plugs and other parts were removed from the cylinder, leaving them open to the atmosphere, and that then, after replacement, the engine started on the remaining mixture, on the spark, ever happened, or could be made to happen."

A year or so ago I recall having read in one of the automobile journals of a man who did this particular stunt with a four-cylinder Cadillac and the publication of the item called forth a statement from another man who said he was glad to know of others who had done this feat, as his friends thought it impossible, everybody at that time believing that it was largely a matter of compression.

I own a 1909 three-cylinder, two-cycle, valveless Elmore and I have not only done this stunt once, but several times before witnesses. Harry S. Kendall, of this town, has also had the same experience. B. A. Lemont, of 6 Tirrell street, Worcester, Mass., while demonstrating to a prospective customer who expressed doubt regarding this feat, stopped the engine, removed the plugs, replaced them, pressed the button and the engine started on the spark. The experiments mentioned were all done with the same make of car.

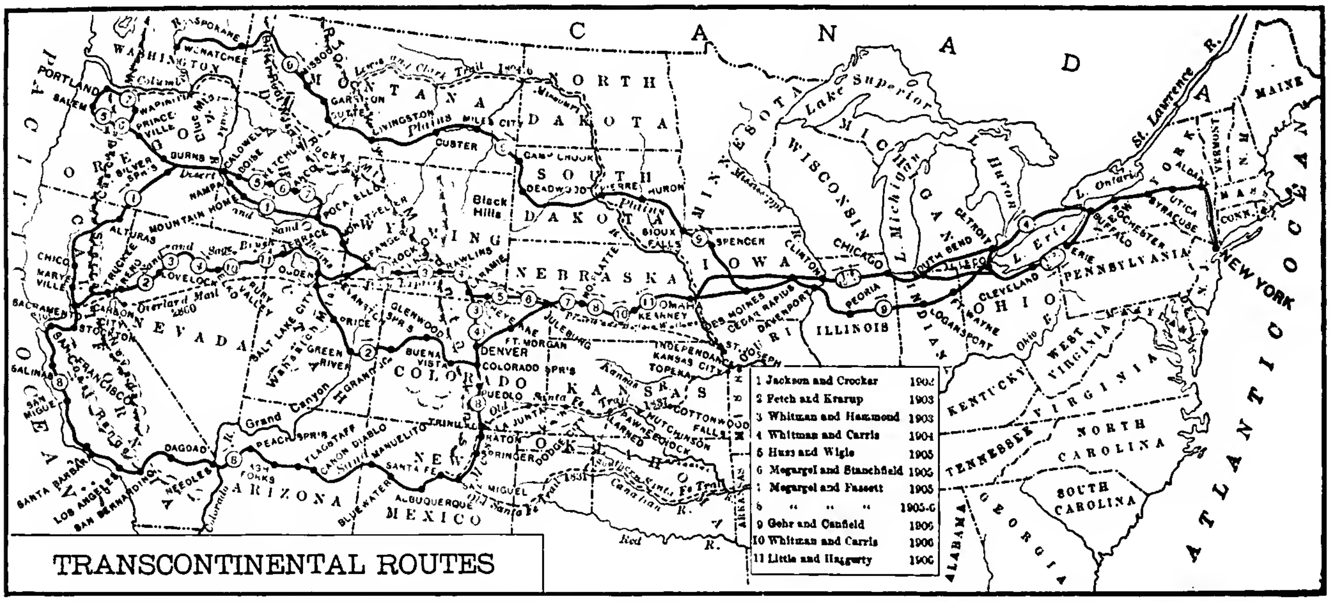
I presume that this experience is more likely to happen with a two-cycle Elmore than with the standard four-cycle motors, and it is probable that the character of the ignition system is an important factor.

I believe that any owner of one of these cars can get the same result if he tries it when his motor has been run and is normally warm. If your friends nearby fail to convince you, come to Gardner, Mass., and I will demonstrate that it can be done. Without attempting to discuss the subject technically I am inclined to believe that the "manufacturer" was within hailing distance of the truth when he told No. 2,201 that "Compression had very little to do with it."

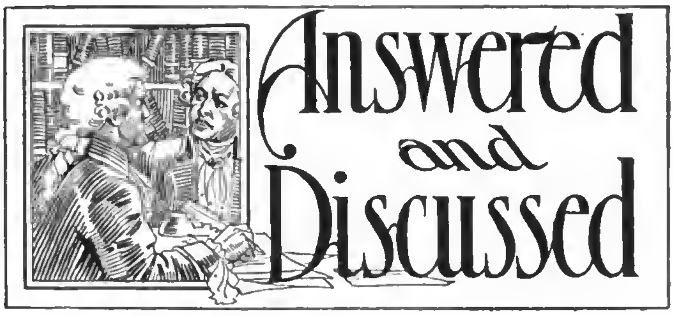
Now I would like to know what kind of car "Manufacturer" used when he performed the experiment.

Gardner, Mass. GEORGE L. MINOTT.

Starting on the spark is not positive, as will be appreciated. To what extent it is possible to depend upon this method of starting is speculative; much depends upon the characteristics of the motor used. If the compression is tight, that is to say, if the motor packing rings are in good order, and the mixture is kept in and is not much diluted with cylinder oil, it is very likely that the spark will be efficacious even though the compression is almost down to the atmospheric line. The spark must be of the effective kind, delivered at the right time, and all the other conditions must be in complete harmony. In view of the interest which seems to be taken in this matter, it will be discussed at some length and in considerable detail, in all probability in the next issue of THE AUTOMOBILE.



Map From Automobile Blue Book, Showing Ocean to Ocean Routes Used by Famous Transcontinentalists, and Best Roads



Best Route Across the Continent

Editor THE AUTOMOBILE:

[2,274]—Can you advise me as to the best route to take in my automobile for the Pacific coast? I am inclined to favor the Southern Pacific railroad via El Paso if I could be sure of getting the necessary supplies. I will take my family along with me, seven in all. I will drive a Chadwick; my destination is Oregon.

New York City. K. C. MILLER.

Referring to the Automobile Blue Book, Vol. 4, "The Middle West," the map as here reproduced affords information as to the routes which were surveyed, and the trips thus far made by the several automobile explorers will be found. The text of the same book, edited for this occasion, affords information as follows:

A brief outline of the general conditions certain to be encountered will help explain what is to follow. To begin with, so far almost all motor-car travel westward from the eastern edge of the Rocky Mountains has had as a starting point either Cheyenne, Wyoming, or Pueblo, Colorado. These two cities, though both at altitudes of about a mile above sea level, are neither of them in the mountains, being simply at the extreme western border of the great alluvial plains of the Mississippi Valley, across which they are approached by an ascent so prolonged, uniform and gradual, that only the evidence of a barometer is convincing to the effect that one is not traversing level country.

Also, until the eastern motorist leaves the Mississippi Valley by way of one of these two cities, he will encounter no conditions of a type with which he is unfamiliar. If he is unfortunate as to season, he will find some bad mud and less bad sand, but on the whole will get along about as in his home locality; perhaps occasionally delayed for roads too dry, or possibly by the necessity for horse aid if he carelessly blunders into too deep sand with too small tires. Roads he will find better than the average, unless wet, all water courses are bridged, settlements are close together, gasoline is low-priced and abundant, and night stops always can be made in towns where accommodations are both good and reasonable.

It is not until after entering the mountains that new conditions, in many respects beyond the imagination of the non-traveled easterner, supervene. From Cheyenne, through southern Wyoming to Ogden, Utah, and from Pueblo, through the Royal Gorge of the Arkansas River to Salt Lake City, the two practicable routes through the Rockies converge to their Utah termini, forty miles apart. From Ogden around the North shore of Great Salt Lake there is a choice of main routes, each about one thousand miles long, into San Francisco along the line of the Central Pacific Railroad and into Los Angeles by cutting down through Nevada and southeastern California—the latter route affording the further alternative toward its end of running either through Death Valley or the Owens River Valley in California.

From Salt Lake City the southern main route can also be reached by leaving along the lines of the Salt Lake and San Pedro, or the new Western Pacific Railroad, soon diverging from these into a run through the mountains to Ely, Nevada. So far as the writer knows no motorist has as yet succeeded in following the line of the "Salt Lake Road" all the way from Salt Lake City to Los Angeles. From Ogden there is a possible route to the northwest, which has been taken by a few transcontinentalists, and at least one car has come east from Los Angeles through Arizona, New Mexico, and Texas, but for the average tourist it will be more satisfactory to follow the better-prospected lines of travel.

Throughout the country under consideration the going becomes chiefly an unending alteration of running through valleys and over summits, even the most desert areas being decidedly mountainous, contrary to popular belief among easterners. Nevertheless the valleys, even in the most unsettled sections will often afford fifty or a hundred miles of ideal speeding. Indeed, there are tracts in Nevada, of hundreds of square miles of almost level ground of natural road material, across which the highways, though improved only to the extent of occasional wheel tracks and sign posts, will admit of full speed with the most powerful cars—though unexpected small gullies are a menace to be kept ever in mind by the driver unfamiliar with the road.

The mountain grades will not disappoint the most extravagant conceptions of them. Again and again before the coast is reached there will be killing climbs of miles upon miles on low-gear, with the ascent always severe and often for very short distances absolutely up to the limits of traction and engine power. Then will follow prolonged descents down which the "tenderfoot" will take the advice of the mountain and desert-wise chauffeurs and brake with his engine, or else learn to his sorrow that three or four hours of continuous down hill, dropping from three hundred to a thousand feet a mile will not merely char brake linings but will absolutely burn the brakes out of a car, wearing the brake drums to shells, and heating them not only enough to blister the paint but even to burn the spokes loose.

Water-cooled brakes and inorganic contact surfaces are of little avail, nothing but letting the car turn the engine over sufficing to dissipate the energy developed in the descent. In this connection there are a couple of tricks worth knowing. One is to disconnect the linkage, if any is provided, between emergency brake and clutch, so that brake and engine can be used together when necessary. Another is that when the car coasts too fast with one gear in engagement, but is not descending abruptly enough to turn the engine over at all with the next lower gear in, keep the lower in mesh and give the motor ignition and just enough fuel to keep the car moving.

In thus depending upon the engine for prolonged braking, it does not follow that the regulation brakes may be neglected. They should be kept at all times in the best possible condition, ready for instant use in stopping on both up and down grades, and for slowing while gear changing during the long coasts—a manipulation, by the way, that will be found just the reverse of the gear changing to which one is accustomed.

In climbing the long grades—sometimes gaining as much as a mile in height in going from 10 to 50 miles, it is of the utmost importance to keep the cooling system in good shape. In fact, there are very few cars in which the carrying of extra water for refilling the radiator will not avoid delays to let things cool during these long climbs. Slipping fan belts, dirt accumulated on the inside or outside of the radiator, or an ineffective circulating pump will make themselves known when their shortcoming would never be suspected under less severe conditions.

Clutches, too, which never cause trouble in thousands of miles of ordinary running, are prone to develop unprecedented weaknesses during long climbs. The safeguard, especially with leather-faced cone clutches, is never to let slipping begin, as once started it rapidly progresses to the ruin of the facing. Dry litharge, dusted liberally upon the contact surfaces, is a western panacea for slipping leather clutches, and as it is not readily purchasable when most needed, a small can of it in the tool box is a safe precaution.

It is particularly important that the tires be of very large section, generally much larger than the normal equipment of the car, this being a secret of successfully traversing bad sand. None smaller than four inches should be used, no matter how light the car. Spare tires must be carried, of course, and an abundance of extra tubes is a necessity, as cemented patches cannot be depended upon in the hot climate. Also, it being any number of times easier to keep going in the sand than it is to start in it, never enter upon a long sandy stretch on the high gear unless the running is down hill, any attempt to change down the gears being almost sure to result in stalling. To start again, when all else fails, a piece of canvas tarpaulin, or even a few gunny sacks worked under the wheels, will do wonders. The car being run slowly on the low gear, the person who places the canvas can by a little hustling easily pick it up and regain his seat.

Bad places, while apt to be very bad, have usually the redeeming feature of being very short. Of the varieties most encountered, there will be "stair steps" in the rocks on grades, excessively steep and abrupt small gullies, fords, patches of deep or very slippery mud, and deep ruts at the sides or high rocks in the middle of the road. The first, on upgrades, can in some cases be surmounted with a low-powered car only by stopping, placing the low gear in mesh, speeding the engine, and then abruptly slamming in the clutch, trusting to good construction to stand the stresses on tires, springs, and transmission. Bad gullies are best taken by "rushing" through on low gear, slowing for just an instant at the bottom of the descent if the rise is very abrupt.

Fords with hard bottoms may be taken at high speed, and must be if very long, or else the water whirled into the bonnet from below will drown the engine. With high-tension ignition it is very easy in fording to cause short circuits that may require hous to dry out. Naturally, the drying-out process is more conveniently accomplished ashore than afloat, from which the logic of "rushing" through is apparent. A ford with very sandy bottom or an abrupt bank on the far side is better rushed on one of the lower gears. A ford with a rough bed of rocks is most treacherous of all, and, if possible, must be gone through slowly. If found in combination with high banks, it may have to be rushed at some risk, on low gear.

The worst place between Los Angeles and Utah is a ford of this description at Twin Springs, Nevada. Piling a lot of sage brush into bad fords or gullies often will reduce the difficulties of getting through. Mud, unless very deep, can be traveled through rather easily with tire chains, while ruts and rocks will do no injury to any car with reasonable clearance if some care is taken in picking the road. Though the desert and mountain roads are very bad in spots, that they do not average so can be inferred from the fact that in one instance of which the writer knows a four-inch tire, with nine hundred pounds on the wheel, ran from Los Angeles to Ogden without pumping.

In Nevada there are some automobile roads roughly maintained by the automobile stage lines that have been responsible for the development of so many new mining camps, and as horse trespassing on these is a penitentiary offense, the sage brush grows high between the wheel ruts. And as it "whips" under a fast-running car it has a trick of turning on gasoline and water drain cocks if these are exposed and the precaution is not taken of wiring them shut.

Many of the runs between settlements are of such length that no standard cars are built with gasoline capacity sufficient to cover the distance, so the carrying of extra gasoline becomes imperative. As gasoline is commonly sold in five-gallon square cans in the west, two cans in a wooden case, these can be fastened to the running boards or elsewhere on the machine. They must be well secured against rattling about, or they will surely develop leaks. The same sort of cans can be conveniently used to carry water. It should be made a rule never to leave a settlement where gasoline or water is to be had without laying in a supply, unless it is positively known that the next supply can surely be reached without trouble.

Carelessness of this sort, in conjunction with a fuel consumption of a third of a gallon a mile through a long stretch of bad sand, once occasioned the writer a 30-mile walk across the desert and two days' delay. Gasoline is cheap on the Pacific Coast and east of Great Salt Lake, but the prevailing prices, even along the railroads, are 40, 50, and 60 cents a gallon throughout the desert country. When there is time enough, and the schedule is sufficiently well defined, gasoline can be shipped ahead for less than it can be bought from point to point. Water is as important as gasoline, for both car and occupants. A five-gallon can for the machine and a couple of two-gallon canteens for the passengers will be about right. With plenty of water to drink the dry desert heat is much more bearable than the humid weather of eastern summers, but without water for even an hour the hardiest begin to suffer, especially should any walking be necessary, while a "dry camp" is a desert synonym for misery. Much of the water that will be found is undrinkable, so the advice on this score should be had from the natives.

Lubricating oil of proper quality is almost impossible to secure except at one or two of the big camps, so enough for practically the entire trip should be taken along.

Dry cells can be had in a few places, and when had will quickly deteriorate, if not already in bad condition, from drying out. Storage batteries can be charged once at most in the course of any possible trip. The result is that magnetic ignition of some type is imperative if serious ignition troubles are to be avoided.

Good lights are desirable for camping rather than for driving, as night running under no circumstances should be attempted. As surely as it is it will result in getting lost, for no matter how well the road itself may be illuminated, the inability to keep track of the general topography of the country will end in missing the road, which, being ordinarily a mere wagon track, can be easily confused with some similar track, perhaps made months before, branching off to one side.

The route should be inquired and verified at every opportunity, as a hundred-mile run without meeting any one is always to be anticipated. In contradistinction to first ideas of the tenderfoot —accustomed to rural ignorance of local geography in the populous eastern states—directions secured from teamsters and others can be depended upon absolutely, even the mileages given often coming out almost exactly on the odometer. Ignorance of the road through the deserts may too easily mean calamity to be permitted to any one. Pencil sketches should be made embodying information secured, distances being such that the best memory is scarcely capable of following the often complicated directions. The post-route maps issued by the government will be helpful, while the topographic maps are particularly useful to the extent that they are to be had for the localities traversed.

By careful planning and avoidance of unscheduled delays, night stops can be usually made at some sort of habitation, but a camping outfit, including blankets and perhaps pneumatic mattresses or sleeping bags, is certain to come in handy, while if it is regularly used it will reduce expenses materially, besides affording complete independence of any schedule. A several days' supply of condensed foods, together with an alcohol cooking outfit, also will prove its usefulness, besides being another means of saving money. A tent is not particularly necessary, as rains are very brief and uncommon during the season when motoring is practicable, but the car should have a top if only to protect from the sun, while a tarpaulin can be used as a protection against any inclement weather that may chance along, besides being useful in sand to keep dust from the baggage, etc.

A very important precaution, which can be neglected only to be regretted, is the care of the skin. The alkali invariably present in the desert dust is excessively irritating to the most calloused complexion if permitted to enter the pores, and often causes violent acute eczemas that can be counted upon to spoil all enjoyment for a week or ten days. The only preventive the writer knows of is the rather disagreeable but quite efficacious expedient of thoroughly greasing face, neck, and hands with cold cream before each day's ride. Washing in strongly alkaline water also is to be avoided, it frequently proving worse than going dirty.

New French Rating Formula Considers Stroke

By MORRIS A. HALL

IN the issue of *Omnia*, Paris, for April 23, Louis Lacoin, the French engineer and designer, gives a new rating formula, which considers not only the stroke as well as the bore, but also the speed. The result is arrived at through a consideration of the volumetric capacity of the cylinders, which is found by multiplying the area by the stroke times the strokes per minute. The area being found directly from the bore times a constant, this constant may be introduced in the formula. So, too, with the number of strokes of the engine, this may be figured as the number of revolutions per minute times a constant, and the latter introduced into the formula.

Considering the bore, stroke and revolutions, a formula for the power developed would take the form:

$$P\ (\text{power}) = K\,d^2\,c\,n,$$

in which K is a constant, d the bore, c the stroke, and n the revolutions per minute.

From a minute and unconsequential consideration of these various items, and their relative bearing upon the final result,

$$P = \frac{d^{1.5}\,c^{1.2}}{12{,}500}$$

which is for ordinary service, but which for test or short trials may be slightly greater, a more accurate figure being obtained from the second formula of similar nature:

$$P = \frac{d^{1.5\ 1.2}}{10{,}000},$$

As the author says, "This formula is remarkable in that the exponent of the bore, d, is less than two. Many formulas have been proposed in which d and c were used, but never has the evaluation of the bore been given a lesser value than the second power. These older formulas have been found to be close enough to the results found in actual practice, so that the ratio of the bore and stroke does not vary between wide limits."

All the above formulas apply to motors with four cylinders.

Speaking further on the subject of the ratio of bore to stroke, the author says, "Suppose, for instance, that this ratio be taken as 1.2, then the formula assumes the form:

$$P = \frac{d^{2.7}}{8{,}000},$$

an expression which shows that the bore d has a value between two and three."

In the accompanying tables, results as obtained from the formulas given (with the 10,000 denominator), with usual sizes of engines are given, while for the sake of comparison the English equivalent of each size of bore is given, and, in addition, a full table of A. L. A. M. horsepower ratings for usual sizes.

In comparing the two results, it will be noted, for instance, that a four-cylinder, four-cycle engine of 4-inch bore would rate at 25.6 horsepower by the old or A. L. A. M. formula, while with equal stroke, that is, four by four, it would rate at something over 25.1, that being the power for an engine of 3.94 bore and stroke. Moreover, with the stroke increased to 110 mm., or 4.33 in., the power rating moves up to 28.1, and for successively longer strokes of 120 mm. or 4.73 in., 130 mm. or 5.12 in., 140 mm. or 5.51 in., 150 mm. or 5.91 in., the rating moves up to 31.3, 34.4, 37.6 and 40.8 horsepower, respectively.

Since the use of metric units in this country is very limited the formulas are of little benefit, unless rendered into other and more common units. With this idea in view, the writer has made the conversion, in which case the formulas assume the form of:

$$P\ \text{average} = \frac{d^{1.}\,c^{1.2}}{2.01},$$

and

$$P\ \text{trial} = \frac{d^{1.}\,c^{1.2}}{1.61}.$$

Both of these would be simplified, and thus, made more suitable for universal use by dropping the last figure of the denominators, making them, respectively, 2 and 1.6. This would make no real change in the result, the increase being slight.

HORSEPOWER OF ENGINES OF A GIVEN SIZE BY THE NEW FORMULA

Diameter mm first In. sec.	Stroke 90	95	100	105	110	115	120	125	130	135	140	145	150
60 2.36	10.3	11.0	11.7	12.4	13.1	13.8	14.6	15.3	16.0	16.7	17.5	18.2	18.9

140 5.51											62.5	64.9	67.5
145 5.71												68.5	71.1
150 5.91													75.0

A. L. A. M. STANDARD HORSEPOWER TABLE FOR COMPARISON

Diameter mm first In. second	Power	Diameter mm first In. second	Power	Diameter mm first In. second	Power
64 2 1-2	10.0	95 3 3-4	22.5	127 5	40.0
68 2 5-8	11.0	99 3 7-8	24.0	130 5 1-8	42.0
70 2 3-4	12.1	102 4	25.6	133 5 1-4	44.1
73 2 7-8	13.25	105 4 1-8	27.25	137 5 3-8	46.0
76 3	14.4	108 4 1-4	28.9	140 5 1-2	48.4
79 3 1-8	15.65	111 4 3-8	30.65	143 5 5-8	50.65
83 3 1-4	16.9	114 4 1-2	32.4	146 5 3-4	53.0
85 3 3-8	18.25	118 4 5-8	34.25	149 5 7-8	55.25
89 3 1-2	19.6	121 4 3-4	36.1	152 6	57.6
92 3 5-8	20.25	124 4 7-8	38.0		

Despite the form of the formula given, and the fact that the table is figured for metric sizes, the inch sizes may be found from it by interpolation. Thus, to find the power rating of an engine of 3-in. bore and 4-in. stroke, take the power for the nearest bore and stroke from the first table, namely, 75 by 100 mm, which power rating is 16.3. From the other table the true size is found to be equal to 76 by 102 mm. In the first table the difference made by increasing the bore 5 mm. is found to be 1.5, so the difference for but one additional mm. would be but one-fifth of this, or 0.3, making the result 16.3. Again, the stroke increases the rating but 1.0 for 5 mm., or 0.2 per mm. The increase here is 2, or twice that, making the total 16.7.

While the formula does not result in a form which is useful in the sense that the present very simple formula is useful, it presents a form long desired, that is, one that considers the stroke. Moreover, to anyone really desirous of figuring out a representative power rating, the figuring presents no difficulty.

(*Continued on page* 984.)

When a New Body Must Be Purchased

By G. J. M.

TIME makes inroads upon the general appearance of an automobile, sometimes at a rate which far exceeds the rate of mechanical depreciation, and the question arises as to the expediency of replacing the body, rather than to purchase a whole new automobile. In the past it has been found a little difficult to replace a body, partly due to the unwillingness of makers to go into this sort of work, and, as styles change with considerable rapidity, it becomes a question as to whether or not one would care to replace an old body with one of the same shape and style.

There are now in use a large number of automobiles which have seen so much service that it is a question of replacing the body with one that is more up to date, or replacing the automobiles rather than to ride in cars that are obviously out of style. This question of style is not to be lightly thrust aside; every man, no matter how much he may try to present an elephant's hide, is bound to find himself a little thin-skinned in the face of ridicule, and the latter is bound to be his portion if he circulates among his friends in an automobile of an ancient vintage, as it were.

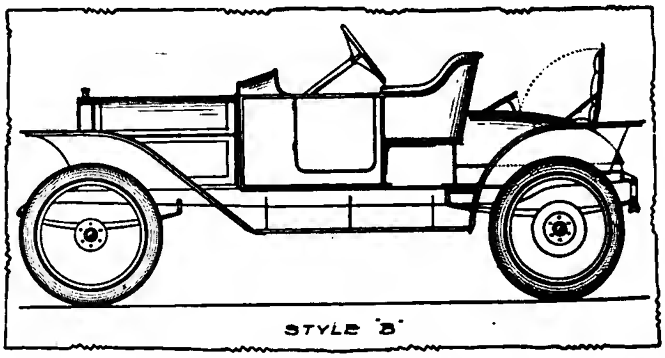
Making an Automobile Look Up-to-Date

The body may cover a multitude of sins, and yet the automobile may look as spick and span as a new creation just from the maker. It is all in having a modern body on the chassis. Of course, it would be poor practice to have a new body made for the old automobile, and not look after the mechanical features of the same. While the body is being made it will be a good idea to have the mechanical portion of the automobile put in the best possible order, the idea being to place one's self in a position to appreciate the good qualities of the new body when it arrives; this is but a matter of having the rest of the automobile in good running order. It is a natural assumption that it will be capable of being put in good order, otherwise it will scarcely be worth while to go to the cost of a new body.

The problem here, under the circumstances, is to show the most modern body work, and a little later, before this series of articles runs out, apply them to real automobiles, thus giving the touch of practicability. The four types of bodies, A, B, C and D, will give a wide range to select from, and they will be so designed, with all details of framing, etc., shown, that they will go on a Cadillac "30" chassis, which is taken as a model to employ in this undertaking, although, as will readily be appreciated, any other automobile will serve the purpose, it being only necessary to conform to whatever differences in measurements there may be between them.

Characteristics of the Four Types of Bodies

Style A shows the body without attachments, i. e., the platform clear for carrying luggage. This platform is 40½ in. long by 33 in. wide, and is formed by boarding across between the side sills. The seat is individual or bucket shaped, with straight line panels of metal; it is 18 in. high in a perpendicular at the back from under the trimming to the seat base line. The underbody is 10 in. high, and from the base line of the sill to the top of the door is 21 in.; from the back of the dash to the front of the seat frame is 32 in.; the door opening is 18 in., and the hood is 9 in. in a horizontal line from the front of the dash. The door, which is on the left side only, is capped with a mahogany wood strip from the hood to the trimming, and the right side is made to correspond. The door has been made to swing from the front, and the lock handle is on the inside; this is done to give a smooth appearance on the left side to correspond to the right. The structure is wood framing with metal panels and moldings. The trimming is generously thick and tufted, and the size of the cushions is 18 in. deep from front to back by 18 in. wide by 5½ in. high or thick at the front and tapered 2 in. toward the back; the height from the top of the floor to the top of the cushion is 14½ in. The trimming is carried on the sides on a line with the top of the door to the back of the dash; this latter is either painted or finished mahogany, and the under side of the hood is painted. The gasoline tank is under the seat, and by utilizing all the space down to the chassis frame a tank holding approximately 18 gallons can be carried. The hand levers are on the outside of the body sides. In our illustration the quadrant is right to permit of this; in case of the quadrant being closer to the chassis, one lever is placed inside

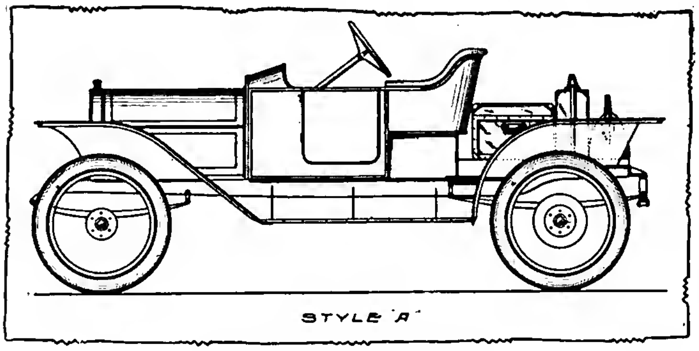


Torpedo stern attached to runabout body as shown in Fig. 1, with a seat for one; it is a popular idea

and one outside of the body; this is accomplished by bending the levers in opposite directions, and making a housing or cut-out from the bottom of the body high enough to fit over the quadrant.

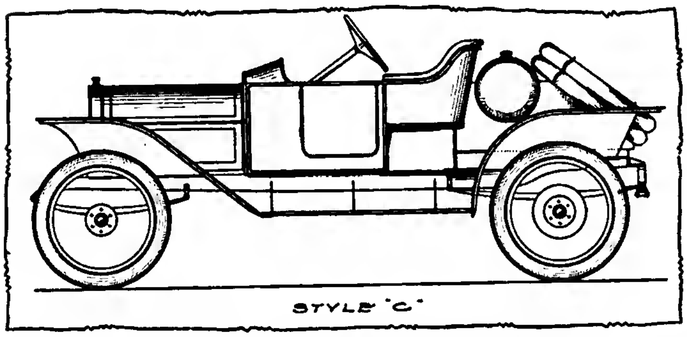
Style B shows the torpedo stern attachment assembled on A. This torpedo stern is entirely self-contained; at the front end where it is assembled to the seat, there is a panel shaped to the curvature of the seat, and also to the line of the underbody. The well, or lid opening, at the top, has a raised ledge or coping to keep out the water, and along the base line a tee molding is fastened, the projecting edge of which laps over the platform edge on the sides and the rear fastenings are by clips or angles secured to the platform by set screws, the same holes on the platform being used for all the different combination attachments. The lid is made in two parts, the rear or lower half forming the back of an auxiliary seat; this automatically opens when the lid is raised, and when closed fits tight to the lid; the metal top is in one piece of 16-gauge aluminum.

Style C shows the racy type assembled to A. This is made of metal also, with wood sill or frame at the bottom. The lid is sometimes made the full size of the sloping back, and the extra tires are fastened to this. To gain access to the interior when the extra tires are in place, one opens the lid, and the tires move outward with same. A small lid that will open inside



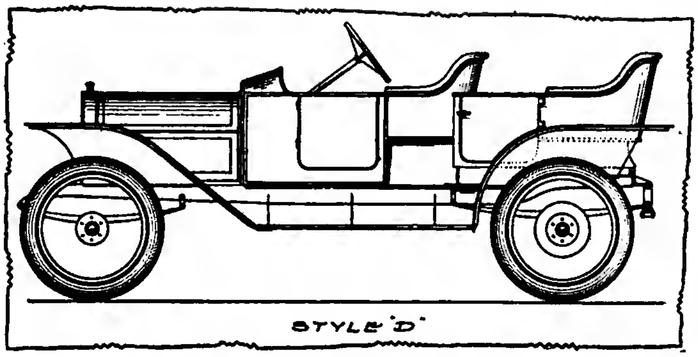
Type of runabout body with a clear platform at the rear to accommodate luggage and what-not the tire opening is most convenient and is illustrated in the working drawing that will follow. This attachment C is entirely self-contained similar to style B at the front, and under the tank are watertight panels; the lid opening is protected by a raised coping and tee moulding is used to keep the water out at the bottom. The tank is secured in place by steel straps that pass over the upper part of the tank and are fastened to the top edge of the body with machine screws.

In style D is shown the parts assembled that go to make the conventional toy tonneau. The door and the seat are made to conform to the design of the front, the seat being made for generous room for two seatings; dimensions are 18 inches from the rear of front seat to the front of rear cushions; the size of cushion is 39 inches long across by 19 inches deep back to front by 6 inches deep or thick at the front and tapered 2 inches toward the back. The style of trimming will conform to that of the front seat, and the doors will have pockets on the upper half; on the top of the doors are mahogany finish strips. The door lock posts at the front are fitted close to the front seat



Racy type of runabout body with a gasoline tank, and tire equipment on the deck back of the driver's seat

panel, but do not touch same, therefore the painted surface is not marred or scratched, and when the tonneau is removed, the true runabout effect is preserved. The door opening is 18 inches



Toy tonneau with a "gunboat" cast; it represents the newer idea, and offers the advantage of being compact

and at the bottom, ahead of the mudguard, the opening is 6½ inches; this is ample room for this type of body, as when entering or leaving the tonneau room for one foot will be found sufficient, provided there is sufficient room higher up, on a line with the hips. A small step is shown on line with the top of the chassis frame; this can be used as the top of the housing over the front end of the rear spring. As the floor of the platform is 2 inches higher than the floor of the front, there is provision for the two front boards to be removed, and below this upper boarding are permanently secured floor boards, on a line with those at the front; this is to permit of sufficient leg room in the tonneau; the detail will be illustrated in the working drawing.

The general appearance of the four types of bodies will be very much as here depicted, and it will be to the advantage of the interested autoist either to use the design selected, without any modification, or have new designs completed for whatever body is selected, on the ground that the result may be very disappointing if modifications are agreed upon without going to the trouble of proving that the appearance will be that desired in the finished automobile.

(To be continued.)

Colors in Their Relation to the Automobile

By M. C. HILLICK

THE most important detail in the process of painting and finishing for the automobile is the selection of the color or color combination to be used, and the application of the same to the surface.

The chief reasons for painting the surface of an automobile body are the protection of the surface by the pigment and the sense of luxury conveyed by the colors. A fitting color which is properly placed upon an automobile of unpromising design will often serve to relieve the ugly features of the car. As is admitted by designers, form, outline and design are, to a large extent, subject to the influence of the color employed.

Within the last two or three years the importance of the use and disposition of colors upon automobiles has come to be widely recognized by all parties connected with such vehicles as users and sellers. Color effects have been found to influence the sale of a car and proved to increase the pleasure of an owner in his machine.

Probably the most preferred color is, at this time, the one which is termed as "red." This color covers a multitude of shades running from light American vermilion to dark maroon. As this year fewer variations of lighter red are being used than during the past years, the public seems to have tired of the "pillars of fire."

The red shades seen most frequently on city thoroughfares are automobile maroon, new maroon, a beautiful deep, rich red, etc., Grosbeak red, deep Agostein red, light and deep, and Julian red, medium and deep. These are opaque colors not requiring, necessarily, a supporting ground.

Among the larger cars, such as touring cars, limousines and landaulets, are to be seen such rare and beautiful lakes of the red order as English and American Ennison lake, medium and deep shade, dark and medium carmine, English scarlet lake, Munich lake, Chatemue lake, and permanent purple. These lakes have grown popular during the past one or two years and the writer has been informed by a traveling salesman for a color-grinding firm that such rare and costly lakes are now sold in 50-pound lots, which formerly were sold in pounds only. They are examples of radiant and effective colors, and their employment is becoming more and more universal among builders and jobbers of automobiles.

During the last two seasons brown has also developed into one of the most desired automobile colors. Various shades of brown have been widely displayed, among them being pongie brown, the original automobile brown, also onyx brown, golden brown, automobile brown, amber brown, Quaker, olive and Detroit brown, and even very fine and nice hazel brown. Browns are commended as a departure from the "sensational" pigments for the light build of cars. They are durable colors, easily handled and will stand a lot of hard usage in service.

Regarding the grays, the use of new, useful and pleasing pigments is confined, in general, to the runabout class and the lighter touring cars. However, many of the larger cars may this season be found painted automobile gray, French gray, light, medium and deep cadet gray, battleship gray, or twentieth century gray.

Studies in Aviation Theory and Practice

By MARIUS G. KRARUP

SUBJECTS for investigation by the aeronautic designer fall into four natural divisions: 1, sustentation; 2, equilibrium; 3, propulsion, and 4, materials. As has already been indicated in introductory articles appearing in recent issues of this journal, the questions relating to sustentation are those which were solved, in a fashion, when the first aeroplane flew. While improved sustentation will permit more substantial construction and a greater independence of wind and weather than is at present enjoyed, the safety of life and limb is more closely bound up with improved equilibrium, and the value of aviation for practical traveling purposes is more closely connected with the improvement of propulsion. Therefore, while the principle of sustentation of weights in the atmosphere is the most fundamental principle for flight, it is the one which at present is best worked out. Giving least concern, it may be passed in review rapidly.

It is approximately true, as found by laboratory tests and confirmed in practice, that a plane of a curvature of one-eighth at a tilt of 7 degrees will support a weight about five times greater than the weight—or force in "gravitation measure"—required for driving it in horizontal flight. Graphically, as in Fig. 1, 250 pounds in a form offering a minimum of air resistance, and hung from a frictionless pulley, can by the gravitation of its mass reach sufficient speed to pull a plane, such as described and weighted to a total of 1250 pounds, horizontally through the air, provided the weight suspended from the plane be so distributed as to hold the plane in equilibrium at a tilt of 7 degrees, but, if the weighty portions in themselves produce a considerable air resistance, some allowance is to be made for this resistance which reduces the weight-carrying capacity of the plane. If the equilibrium is changed so as to produce a higher tilt, the plane will offer more resistance to propulsion, but if increased power makes it reach the same speed as before, it will support more, even considerably more, or, with the same weight, it will rise in the air at an inclination proportionate to the increase of tilt, so long as the angles remain small. But at the high tilts, from 15 to 30 degrees, where the maximum of sustentation is reached, the increase in sustentation progresses at a considerably slower rate than the increase in tilt. Under all circumstances the sustentation does not begin until some speed has been reached. In the graphic example of Fig. 1 the falling weight must have gained some headway before the plane can leave the ground. The speed required depends upon the area of the plane, while the propulsive thrust needed for reaching the required speed, for a given area held at a given tilt, depends upon the skill of the designer in minimizing those factors which offer resistance without contributing to sustentation.

With planes of smaller curvature than one-eighth, the sustentation produced is smaller, but the resistance to propulsion is also smaller, and the higher speed required for sustaining a weight five times greater than that which measures the power is reached as readily as the more arched plane reached the lower speed required for it, and it seems probable that the sustentation obtained now by means of planes with an one-eighth curvature may be produced with planes offering less resistance through simple improvements in design and materials.

From the foregoing it is evident that sustentation does not depend on power, in the sense that the plane should fall rapidly when the power ceases to act. The machine's own weight, say, 1250 pounds, when allowed to descend at an angle giving one foot drop for every five feet of horizontal displacement, supplies in itself a power equal to the vertical gravitation of 250 pounds and is therefore sufficient to maintain the 1250-pound machine at that angle, and by employing planes of a sufficient area both the speed and the angle for an involuntary or voluntary descent may be reduced, without the use of propelling power, wholly according to the skill of the designer. The less resistance the machine offers of the kind which does not contribute to sustentation, the more gradual the descent by gravitation may be made for a given relation between weight and area of the plane.

In Fig. 2 curves are plotted showing the support derived from one square foot of area at speeds of 15, 20, 30 and 40 miles per hour by a plane of one-eighth curvature. Where the curves are wavy, an unstable support, due to shifting of the center or axis of pressures, is indicated. The curves are approximated from actual flying practice and the tests conducted by Rateau, Brillouin, Eiffel and Ribouchinski. Fig. 3 similarly presents comparisons between propeller thrusts required at the average aeroplane speed of 25 to 30 miles per hour, and the weights supported by means of these thrusts, in planes of different curvatures, but it is evident that the curves shown cannot be highly accurate and that they are destined to be superseded, as soon as designers shall have learned to get the sustentation from a plane of one-fiftieth or one-thirtieth curvature which is now obtained only if the one-eighth curvature is employed, or in the case of any other important improvement in planes being made.

With regard to sustentation, the situation lies then so satisfactory that the designer need not worry. With curvature, area, tilt and speed all measurably at his command and all adapted to produce sustentation, he finds himself in position to support all the engine power which he should need and all the extra load which there is any immediate necessity for carrying. Between 15 and 50 miles per hour he has *carte blanche* to juggle with areas, curvatures and tilts in order to get support for his structure. If it is so constituted that he can drive it into the air with his power equipment it is *eo ipso* also so constituted that it can be made to descend gradually without power, provided he is high enough up in the air, when the power gives out or is shut off, to allow him a second or two for operative control action. But if the designer wishes to fly at a smaller speed than 15 miles, he must invent decisive improvements over present construction. In order to rise into the air at a moderate speed, he only has to provide a propulsive power which, measured in pounds, equals one-fifth of the weight of the structure. He can then have either a large area with small curvature or a smaller area with greater curvature, and in either case he can produce variations in sustentation by varying the tilt. By choosing both large area and large curvature he can reduce his power much below one-fifth of his weight and still have enough sustentation for rising. He can finally reduce both area and curvature and manage to rise by high propulsive power and high tilt, but if he manages so closely as to require the high tilt constantly, he will have little range of tilt left for control purposes—as in the Santos Dumont "Demoiselle" type—because the useful and dependable tilts, with present limitations of construction, vary in practice only between 5 and 20 degrees.

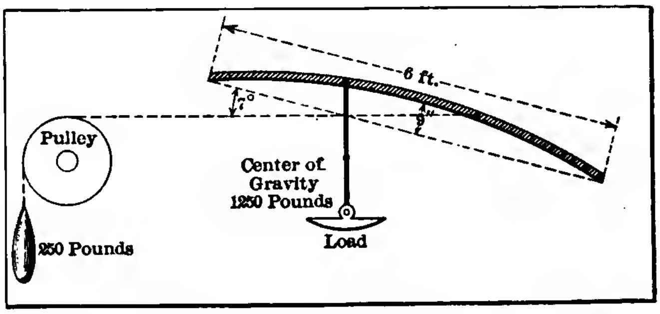


Fig. 1—Illustrating Principle of Sustentation by Aeroplanes

Even at the present stage of the science of aviation, the question of sustentation is then practically reduced to the question of producing a suitable propulsive thrust, and, on the other hand, of so shaping the machine that this thrust is translated into speed with as little waste air resistance as possible, and particularly to produce a thrust which will equal or nearly equal in power the gravitation of one-fifth of the machine's weight. This is already accomplished with the engines, planes and propellers now in use, but the greatest diversity of opinion exists with regard to the proper means for measuring the propeller thrust. The designer requires to know what his propeller will do in combination with the engine at his command and with directly comparable reference to the weight which he has to sustain. It is of no value for him to know how many cubic feet of air the propeller will displace or thrust in any given direction, at one speed or another. Calculations on these points simply change the large bill of foreign denomination into small coin equally foreign and not possible to pass current for the transaction in hand. The thrust produced by the propeller must be known in terms which have nothing to do with the dynamics of the atmosphere, which themselves constitute the subject under investigation.

The most suitable unit for measuring the thrust—without going into the scientific refinement of employing the absolute units, ergs and poundals for measuring force and work—would seem to be the one usually employed, which is the gravitation force of one pound, or of one kilogram where the metrical system is preferred. The gravitation force of one pound is equal to about 16 foot-pounds, while one horsepower equals 550 footpounds, so that the sustentation of 34 6-16 pounds in a vacuum equals one horsepower. If the measure of propeller thrust in pounds shall mean anything definite and applicable, and something in which the confusing element of air resistance is not introduced in the very unit of measurement for a dynamic action in which air resistance is the most important element, one pound of propeller thrust must then mean 16 foot-pounds of propeller thrust, and 34 6-16 pounds of thrust—if the thrust has been ascertained and measured with reference to the weight it will sustain—must mean one horsepower delivered by the propeller. The methods adopted in practice for measuring propeller thrust do not always agree with this view of the subject, but if it is accepted as nearly correct, it is seen that a thrust of 250 pounds for a propeller driven by a 30 or 50 horsepower motor represents only a delivery of 7 3-11 horsepower. And in the practical flight of aeroplanes this thrust represents at present all the power actually utilized for sustaining and driving a machine weighing 1200 pounds or more, at speeds ranging from 20 to 50 miles per hour. The work done by the delivery of 7 3-11 horsepower compares therefore favorably with the work done in driving an automobile at a similar expenditure of power. The waste is between the engine and the propeller thrust; that is, it is in the propeller design. In early automobiles a similar waste took place between the engine and the rear wheel rims; that is, in the gear transmission. High claims for efficiency in transmission gears were made then, and similar high claims are made to-day for efficiency in propeller design, but the true figures, now as then, do not permit the acceptance of the claims. On the other hand, the less efficient the propulsion must be acknowledged to be in the machines which nevertheless fly successfully, the less fault there is to be found with the sustentation and the means by which sustentation is at present secured. While sustentation is subject to improvement, the designer can get along very well with the well-known means currently employed for securing it, and his attention turns naturally to the three other divisions of the subject of aviation: Equilibrium, Propulsion and Materials.

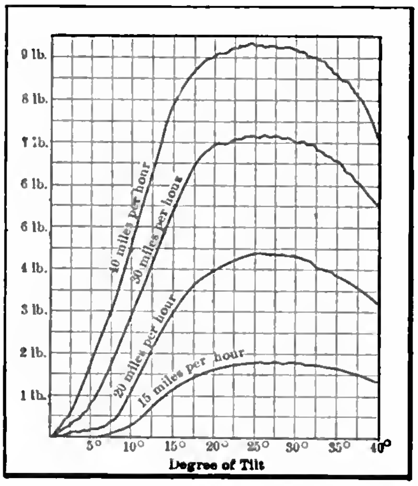

Fig. 2—Approximate Sustentation per Square Foot by Plane of "1/8" Curvature at Different Tilts

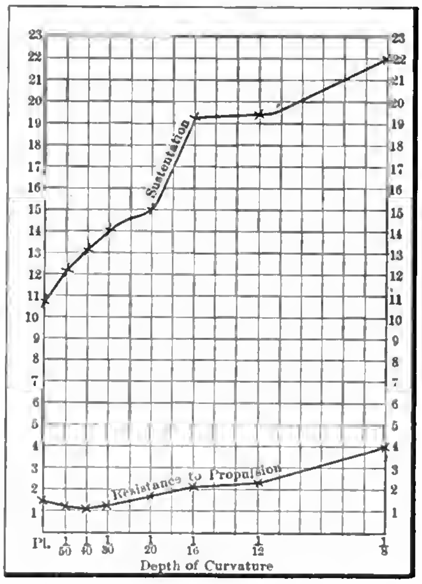

Fig. 3—Approximate Relations between Propeller Thrust and Weight Carried by Planes of Different Curvatures at 25 to 30 Miles per Hour

In the study of Equilibrium which is to follow, the situation is different. While the facts relating to sustentation are becoming known by experiments and practical flying, they remain quite unrelated to the physical laws which are generally understood. The laws which they represent are yet to be formulated. With regard to equilibrium, the laws are generally understood in theory, but their application to a structure which must be light and must be shaped so as to afford sustentation under a wide range of differing conditions presents numerous stumbling blocks for the mind as well as for the mechanic.

Alloys Used As Bearing Metals*

Theoretically all metals have the same friction, according to Thurston, and the value of the soft white alloys for bearings lies chiefly in their ready reduction to a smooth surface after any local impairment of the surface, such as would result from the introduction of foreign metal between the moving surface and the bearing. Under these circumstances the soft alloys flow or squeeze from the pressure into the irregularity, forming a larger area for the distribution of the pressure, thus diminishing its amount per unit of area. Further, the larger the area over which the pressure is extended the less becomes the liability to over-heating and consequent binding.

Lead flows more easily than any of the common metals under pressure, and hence it has the greatest anti-frictional properties. Of course, a number of metals exceed lead in this property, but their cost or some other factor render them unavailable. Lead is the cheapest of the metals, except iron, and in comparison to the other metals used in the formation of bearing alloys their relative prices are somewhat in the following order per one hundred pounds: Lead, $4; zinc, $5; antimony, $9; copper, $13; and tin, $30 or more. It can thus be seen that the more lead is used in a given bearing, the softer it is, the less friction it possesses, and the cheaper it can be furnished. It is, however, too soft to be used alone, as it cannot be retained in the recesses of the bearing even when used simply as a liner and run into a shell of brass, bronze or gun-metal or some other alloy. Various other metals have been alloyed with it, such as tin, antimony, copper, zinc, iron and a number of non-metallic compounds, such as sodium, phosphorus, carbon, etc., and the effect of the different ingredients is to-day fairly well understood.

*From "Machinery."

Elastic Limit of Manganese and Other Bronzes*

By J. A. Capp, Schenectady, N. Y.

TO keep up with the demands upon the laboratory for more work in a given time, testing machines have been speeded up and the slow extensometer has largely been displaced by the dividers, used either unchanged or with some means of magnification. To represent castings and forgings the short test piece with one-half inch diameter and two-inch gauge length is almost universal. As a consequence, while reports of tests usually include a statement of "elastic limit," the property of the material actually determined is in reality that more or less vague value called the yield point. It is the object of this paper to show that while the yield point for steel is so well marked in properly conducted tests, and bears a sufficiently definite relation to the true elastic limit to warrant the dependence placed upon it by the engineer, there is no equally well defined point found in testing bronzes, and the value commonly obtained from rapid commercial tests as the elastic limit or yield point on bronze may be quite misleading.

Manganese bronze was selected as the metal to be subjected to the series of tests here recorded because, of the modern alloys, it is one of the strongest and is readily obtainable in the market. It is not proposed, however, to discuss at length the properties of manganese bronze as such. This metal is used as a type and the results, so far as behavior under a tensile test is concerned, may be taken as typical of brasses and bronzes in general, at least so far as they have come under the observation of the author in some seventeen years of testing materials.

Specifications issued by the Navy Department for manganese bronze, March 30, 1909, required the following approximate composition:

Copper	52 per cent
Iron	1 per cent
Zinc	46 per cent
Tin	1 per cent
Manganese	Trace
Aluminum	0.5 per cent

The specification further required:

Tensile strength	65,000 lb. per sq. in.
Elastic limit	30,000 lb. per sq. in.
Elongation	15 per cent in 2 in.
Reduction of area	25 per cent

They state "the elastic limit is to be the yield point, measured by the drop of the bar."

Manganese bronze castings in the form of cylindrical bars about 1 1-2 inches in diameter by 24 inches long, were ordered from several foundries supplying this alloy; the orders were placed through the regular channels, bars of about this size being required in ordinary production. In this way it was hoped that commercial material would be obtained, such as might be expected in castings of more intricate shape. The results on these specimens, ordered without reference to intended use, checked very well with those upon samples submitted previously by the same parties, especially for the purpose of showing the qualities of their material. To indicate the effect of working upon the metal, there were also ordered two bars of the same dimensions hot-rolled to size, and two bars hot-rolled and cold-drawn. The effect of the cold drawing was lost to a great extent by the necessary turning off of the surface in preparing the specimen for test. Much of the cold-drawn metal is used in this way, however, when screw threads are required to provide means of fastening the part in place in the structure. From the bars so obtained, specimens were turned which provided a test section one inch in diameter by eight inches between gauge marks, and which had, for the purpose of gripping, ends 1 1-2 inches in diameter threaded to fit the nuts required by the testing machine.

Some of these specimens were pulled in the laboratory of the General Electric Company at Schenectady, some in the testing machine at the United States Arsenal at Watertown, and others in the laboratory of the Halcomb Steel Company at Syracuse. The tests in the Halcomb laboratory were made to obtain autographic strain diagrams; the other tests were made with an extensometer.

In the tests with the extensometer, after the instrument had been placed, an initial load of 1,000 or 2,000 pounds per square inch was applied and the first reading taken; readings were then obtained at successive loads applied in equal steps. In some cases the readings were continued regularly until the increase in extension per increment of load was so great that there was no doubt that the strain diagram had departed markedly from the straight line demanded by Hook's law; in other tests the normal succession of readings was continued only until the first positive increase in extension per increment of load was noted, when the stress was reduced to the initial load for the measurement of permanent set, after which the load was returned to the value just left, a new reading taken and the test continued with further determinations of set intervals. The values of stress and corresponding strain obtained were plotted, and the elastic limit recorded as the stress at the point of infection of the curve drawn through the points.

The specimens subjected to these tests were about 12 inches long over all. From the remainder of the 24-inch bars the usual 1-2 inch by 2-inch test pieces were turned and tested in the

the commercial test upon the specimen from the same bar. In Table 2 similar data are given from the test with measurements of set. Table 3 shows the results obtained upon the other specimens tested at Schenectady. The curves for all these tests are assembled on Fig. 1. Details of the tests at the Watertown Arsenal are stated in Tables 4 and 5, and the curves from these data are given in Fig. 2. The results of the work at the Halcomb laboratory are shown in Table 6 and Fig. 3; the scale of the diagram is so small that the location of the point of inflexion is uncertain within about 2,000 pounds actual load, and the values in the tables are placed rather high. The multiplying dividers used in the commercial tests here recorded magnify the movement of the gauge marks about ten times, and are a much more sensitive instrument that the machinists' dividers for locating the yield point, hence the yield points recorded are lower than are usually reported.

Tensile strength, lbs. per sq. in.	80,420	74,780	74,480	74,260

* Bar 9908B was unsound, hence ½ in. by 2 in. test was turned from side of bar, instead of center. Unsoundness due to oxidation and perhaps segregation, probably accounts for the apparent cold shortness of the 1 in. by 8 in. test piece. Fracture occurred in a flaw, while many incipient fractures or cracks were noted in surface before final rupture.

In the text-books and elsewhere the limit of elasticity is defined as that value of stress beyond which there is not full recovery of the initial dimensions or shape of the specimen after release of the load, or as the maximum stress that can be applied without producing permanent set. In other words, it is the value of stress beyond which Hook's law no longer holds, and it is sometimes spoken of as the limit of proportionality of stress to strain.

found for the cast metals ran from 25,000 pounds to 29,000 pounds, and for the worked metals from 30,000 pounds to 44,000.

(To be continued.)

Legal Definitions and Explanations of Words

By XENOPHON P. HUDDY, LL.B.

A NUMBER of the legal controversies which have arisen concerning the automobile and its operation have hinged for determination upon the definition or meaning of the word or term used in connection with the automobile.

Generally speaking, a highway is a way along which the public at large has a right to pass. The term "highway" or public highway includes a turnpike and toll road, also a bridge and a ferry. A navigable river is a highway, so is a railroad. It is only when motor vehicles are operated on the public highways that the automobile laws apply. The owner or operator of a motor vehicle need not comply with any of the automobile regulations if the machine is used on a private road. A man may do as he pleases on his own private property.

In the United States we seldom hear of footpaths, bridle-paths, driveways, highroads, but each of these terms has a definite meaning, and will be found in existence in this country where the common law exists, which is in every State.

If the right of the public is one to pass and repass on foot only, the way is a "footpath."

If the right is confined to riding or leading a horse, the way is called a "bridle path."

If the public has the right to drive cattle along the way, it is a "drift way."

If the right is to drive in carts and carriages it is a "high road."

Only in the United States, especially throughout the country districts, it is customary to use all roads for all the purposes mentioned, still it may not be strictly legal under certain conditions for a person to use the road to drive cattle thereon, when it is being used at the same time by vehicles.

Considering the terms found in use to cover the automobile, we find that the State legislatures have specially defined the terms "motor vehicle" and "automobile" substantially as meaning any vehicle operated by power other than muscular.

The term "motor vehicles" also includes motorcycles, and where a registration law provides that motor vehicles must be registered and licensed, with no specific mention of excluding motorcycles, the latter vehicles are included, according to a recent decision of the highest court of one of our States.

When a person buys an automobile it may not be entirely clear as to what is included within the term. Already dispute has arisen concerning what is meant by a chassis. Manifestly certain accessories would not pass under a contract for the sale and delivery of an automobile. There are certain fixtures, however, which would be included within the meaning of the term, such as tires, the horn, and lights. Inasmuch as the automobile laws provide that motor vehicles must be equipped with certain things, these ordinarily would be expected to be received by the purchaser of an automobile. Chains, speedometers and clocks would not pass, nor would robes and goggles.

The courts have said a great deal about the automobile in describing it. It has been judicially stated that the automobile is not a work of art, nor is it to be classed with combustibles and inflammables, such as gunpowder and nitroglycerine. It is not in the same category as evilly disposed mules, according to the Court of Appeals of Georgia. It is no more dangerous than a sailboat or an ordinary carriage, says the Supreme Court of New York. Motor vehicles are not "household effects" within the meaning of the customs law, but the washing of an automobile constitutes a domestic use of water, and the owner does not have to pay an extra water tax.

The automobile is not a tool or implement of trade, and therefore exempt from attachment, but it is a carriage, according to some decisions. The Supreme Judicial Court of Massachusetts has held to the contrary, however, and declares that the automobile is not a carriage. A very recent decision of that court holds that one who hires an automobile is not guilty of a penal offense because he does not pay for the same under the law of Massachusetts which provides that it is a misdemeanor to hire a carriage and refuse to pay therefor. The automobile is not a locomotive, but a traction engine is an automobile. It is a vehicle, however, and is a "team" within the meaning of the law of Maine, which defines the word "team" as meaning all kinds of carriages used on the public ways for carrying persons or property.

The automobile is not a nuisance unless the driver makes a nuisance of it, which he may do if he obstructs the public highways or causes obnoxious smoke to be emitted from his car.

An automobilist is one who uses an automobile, whether he drives or owns a car, but an automobile driver is one who actually and physically operates an automobile. It has been held, however, that a person who sits beside a chauffeur and superintends the driving of an automobile may be convicted of driving the machine faster than allowed by law, although he did not actually and physically operate it. Ordinarily speaking, a chauffeur is one who drives an automobile for hire and at regular wages. Under the Pennsylvania Act the term means any one who operates an automobile or motor vehicle, and does not necessarily mean the person paid and employed for that particular and exclusive work.

The Garage Under the Law

The garage has been called the modern substitute for the ancient livery stable, but a garage keeper, independently of statute giving him the right, possesses no lien for unpaid charges for storage as is the case of a livery stable keeper. A garage is not a nuisance *per se;* however, it may constitute an "offensive business" within the restrictions of a deed of land prohibiting the conducting a business offensive to residential purposes. It may be a nuisance, however, if proper care is not taken in storing gasoline, especially if frame houses are adjacent to the garage.

In framing automobile legislation it is very important that the terms used should be clearly and explicitly defined, otherwise it may be impossible to accomplish what is intended to provide for. Those things and acts which are expressly included within the law are subject to it. Everything not covered by the law is not within its control. Take, for example, in the State of Vermont, where the motor vehicle law provides for the registration of automobiles, but does not expressly exclude traction engines. The Supreme Court of this State held that traction engines were automobiles, even though the legislature did not require these machines to be registered as motor vehicles. A similar situation arose in Michigan, where it has been held that the term "motor vehicle" includes a motorcycle.

It will be seen that definitions of terms are most important in considering the legal aspect of automobiling.

For Women Who Hold the Wheel

By MRS. A. SHERMAN HITCHCOCK

MOTORING has from its earliest advent proven an exceedingly fascinating pastime for the fair sex, and the women are constantly, through association and experience, learning more fully the mechanical detail of the car and are acquiring greater knowledge of its capabilities and necessities. The motor vehicle has created for women new possibilities for amusement and recreation, and has given them immensely increased independence. The stimulus of speed, the physical exhilaration without physical exertion, and the distance that can be travelled, all conduce to the general fascination, and whether one has been a lover of the horse or an enthusiastic cyclist, there is certainly nothing that can equal the motor car if saving of time and a maximum of comfort are to be derived. The successful woman motorist is the one who makes a complete study of her car and guards so far as possible against troubles arising when driving. Away out upon a country road, inconveniently far from expert aid, a motor woman is wholly dependent upon her mechanical knowledge to avoid delays which, in the majority of cases, are caused by quite simple failures, which might be easily overcome. A motorist should not expect to depend upon others to help her in cases of emergency. When the motor stops upon the road, one of two things is most likely the cause—either the proper supply of fuel is lacking or the means for firing the gas have gone wrong. In the first instance the fault is probably in the carbureter or with the gasoline supply. In the second it is the ignition system that requires attention. If previous to the stop there were weak explosions or a great deal of smoke in the exhaust, the indications are carbureter trouble. If there be missing explosions in the cylinders or back-firing in the muffler, the failure is undoubtedly in the ignition system, although both skipping and muffler explosions are sometimes due to a poor mixture. A common cause of ignition trouble is a short-circuited plug. If a certain cylinder is missing fire and the plug has been examined and cleaned and seems to spark well when the car is running on the level or down hill, but refuses to do duty when a hill is reached, it is an almost certain sign that the plug in that particular cylinder is short-circuiting, either from dirt or oil on the inside, or perhaps because it is cracked. The remedy is to change the plug for a new one. Soot on the surface of plugs often short-circuits them, permitting the current to pass through without forcing it to leap the spark gap. When a car is ascending a hill the motor will gradually slacken speed. The spark lever should be retarded by degrees as the speed of the motor decreases, that it shall not fire before the piston is over the dead centre. Before the motor has begun to run dead slow the gear should be changed and the ignition lever slowly advanced as the engine picked up. Another thing that causes chagrin to the beginner is to have the motor stop because the ignition is advanced too far while the motor is carrying a heavy load. Experiments with both the throttle and the ignition levers should be made until the best results under all conditions are obtained. The beginner will be very much humiliated to find that the reason the car refuses to go is because the brakes are on. This condition is not an improbability with the novice, so that one should be careful to see that the brakes are off before attempting to start the car. Another important thing to observe is that the ignition lever is always set back before attempting to start the engine. The beginner may suffer a sprained wrist, if not worse, from a back kick unless this lesson is well learned. Women motorists are often rather uncertain in starting their car and are fearful of their safety. An absolutely safe method is to have the car in proper condition; then, with the switch open, turn the engine over several times, allowing it to come to a stop by balancing between compressions. After this has been done, if the batteries are thrown in, unless the motor is absolutely cold the motor will be started on the spark.

Sullivan Delivery Wagon

INDICATIONS point to a decided increase in the commercial phase of the automobile, and among the conspicuous new efforts which are now taking form, the Sullivan Delivery Wagon will be mentioned. This commercial is the product of the Sullivan Motor Car Company, Rochester, N. Y., and the particular car here presented is designated as Model "20," and sells for $1,050, which price includes two oil side lamps, one oil tail lamp, horn, and a full set of necessary tools. In view of the diversity of the requirement by the different customers, from the body point of view, each body is made to conform to the particular requirement of the individual purchaser.

Excellence of the power plant is the first requirement in commercial service, not only because the load to be drawn is variable over wide ranges, and even excessive at times, but in view of the lack of mechanical knowledge of the driver, who, more often than not, ranks as an apprentice boy in a grocery store. That the power plant should be self-contained, and include everything complete, back to the universal joint, which intervenes between the driven shaft of the transmission and the propeller shaft of the car, is the idea of the designer in this case, and the manner in which the design features were executed will be appreciated by examining Fig. 1, in which the 2-cylinder opposed motor is placed with the cylinders C2 in the lateral plane, and the flywheel F1 is located at the front end. A close inspection of the whole design discloses a nice relation of the component parts. The radiator is placed just in front of the flywheel, as shown in Fig. 2, with two leads W2 from the top of the cylinders (one from each cylinder); the water passes from the motor cylinders to the radiator, through the connection W1.

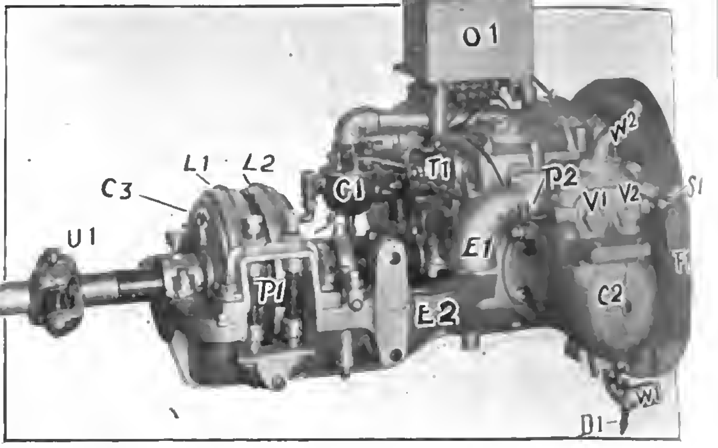

Fig. 1—Self-contained power plant showing 2-cylinder opposed motor, and extension of crankcase casting to house the planetary

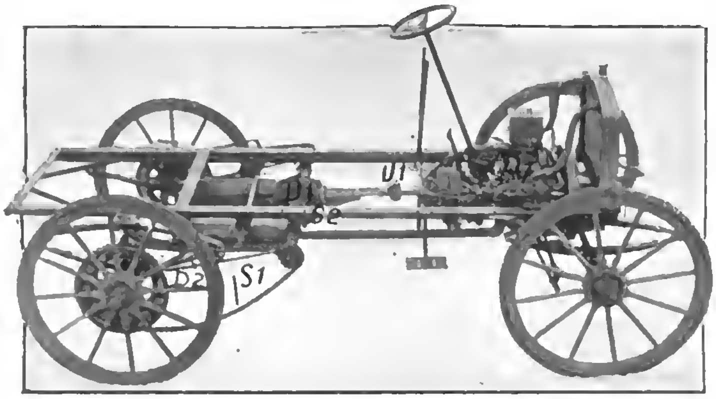

Fig. 2—Chassis presenting the mechanical layout with motor in front, independent differential system, and side chain drive

The planetary gear system P1 is nested in an extension E2 of the motor frame, so that alignment between the motor and the transmission is assured. Accessibility is a point of merit in the design, it being the case that the valves may be gotten at through the covers V1 and V2 for each cylinder; the exhaust connects through the fitting E1, and a relief cock P2 is placed for each cylinder in the plane of the valves at the rear, while the ignition boss which locates the spark plug S1, is at the front in the same place. The Schebler carbureter C1 serves for both cylinders, and is placed in a protected position between the crankcase and the planetary gear on the top side. The timer T1 is also above and in a protected location; it is driven from the end of the camshaft which extends out from the motor case.

The mechanical oiler O1 is placed above the case securely mounted thereon, and the leads, of which there are four, take care of the two cylinders, crankcase and main bearings. Passing back to the transmission gear, which is of the planetary type, the clutch C3 is manipulated for high speed, whereas L1 and L2 represent the bands of the low gear and reverse. The shaft extends back to the universal joint U1, which completes the connection with the propeller shaft in the regular way. The whole power plant is designed for long life and low depreciation. These desirable conditions are brought about through the use of suitable material, capable designing, and careful work during construction, each operation being checked with the idea of holding closely to the proportions which will assure interchangeability.

Accessibility is one of the recognized requirements in commercial work, and Fig. 2 of the stripped chassis shows how this phase of the problem was coped with for a successful issue in this undertaking. The power plant P1 is located at the front end of the chassis, but the load is taken at a point back of the center line of the front axle, and the alignment of the machinery is assured in view of the unit construction back to the universal joint U1. The car is of the side chain drive S1, and the differential gear system D1 is suspended under the chassis frame S2. The differential and bevel drive are self-contained, and the diagonal component of the torsional effort of the motor is taken up by the self-contained differential system so that the chassis frame S2 does not participate in the work, and it becomes a matter of no moment at all as to whether or not its alignment is good or bad. The front spring suspension is of the full elliptic type, but the rear suspension is a full elliptic scroll type. The distance rods D2 are free to maintain the correct axle distance from the jack shaft, in view of the use of the scroll idea in the rear springs, and the side chains are therefore permitted to do their work without being tugged at in any way in response to road inequalities as they affect the movement of the rear axle.

Fig. 3 shows the car complete with a delivery body. Ground clearance is ample, due to the use of large diameter wheels, and the cost of transportation per ton mile for the goods is maintained at a low ebb, in view of the selection of solid tires of right proportions, considering the total load, and the further fact that the load distribution is carefully worked out.

Fig. 3—Delivery Wagon type showing full elliptic rear spring suspension, large diameter wheels, and solid tires

Central New York Relay Club Run Preliminaries

SYRACUSE, NEW YORK, May 23—Leaving here last Wednesday morning Deputy State Commissioner of Highways Frank D. Lyon and a party of State and county road officials, accompanied by J. Arthur Ritchie and Harold N. DeWitt, of the Empire State Motorist, made a thorough inspection of the roads to be covered next week by the Central New York relay club run. At each road district, the district, county and town supervisors were picked up by the official party and taken over the territory that lies within their jurisdiction. Any needed repairs were ordered made by Commissioner Lyon who has guaranteed that these roads will be in as perfect condition as roads can be by Saturday next. As it is, they are almost ideal over 90 per cent. of the distance and but little work was found to be done.

Fig. 1—Hign bridge near Ithaca

This tour, which is fathered by Messrs. Ritchie and DeWitt, is simply a sociability event in every detail with its one object "Good Roads and Fair Laws." There is no contest feature in so far as technical condition of the cars nor their running time within fast limits is concerned. Prizes will be given for the nearest approach to a predetermined secret time that will be very slow and wholly within the limits of the slowest legal regulations.

In a word it is, as the name implies, a relay tour of club members with the exception that many of the clubs will have entries that will drive the entire distance.

The start will be made from Syracuse on May 28 with certain messages from Syracuse officials to Auburn officials. The Syracuse club will carry these to the Auburn club. Here the Auburn contingent will be annexed to carry the words to Cortland where lunch will be had. Then on to Ithaca in time for the Michigan-Cornell game and into Watkin's Glen for the night stop.

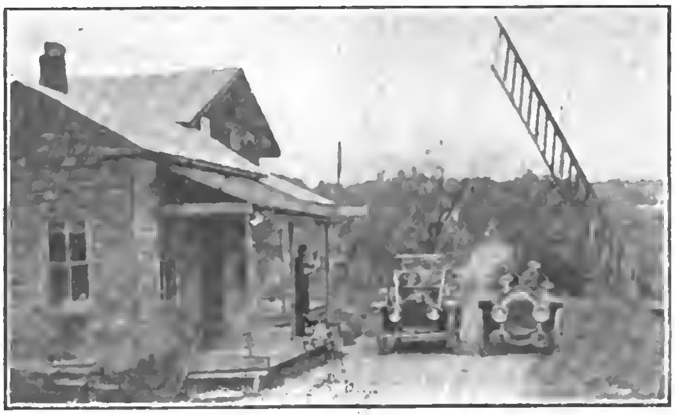

Fig. 2—A bar to progress which has been lifted forever; it costs nothing now, a "quarter" was the charge in the old days

Sunday morning the tourists will be shown through the Glen by guides furnished for the especial occasion.

The third day run will be from Binghamton to Oneonta for noon and Cooperstown for the night stop. The last day will take the caravan back to Syracuse by way of Richland Springs, Utica and Rome.

The fact that the time set for this run will admit of practically three holidays, Saturday, Sunday and Memorial day, and the fact that each entrant can go as far or as little a distance as he desires portend an enormous entry list. It seems likely that more than a hundred cars will enter some of the controls during the Sunday and Monday runs. Every arrangement has been made to care not only for the cars and owners but for the families, the women and children as well.

The survey just completed demonstrates without doubt that those who do participate in the regular run will be treated to a bit of scenery not outrivaled by any traversible road anywhere in this country and to about 400 miles of beautiful earth and macadam roads.

The shortness of the day's runs will enable everybody to drink in to the fullest the beauties of the country, and the spots of National importance such as the Glen will be inspected.

At all of the night controls special entertainment arrangements have been made for the visit of the tourists.

This is the first run of this sort to be held in the State and the novelty of its plan is responsible for the great interest displayed on every hand. The question of local pride is entering into the matter in every way and this helps to keep up interest at high pitch. Each club is anxious to have more entries than its neighbor and each road district to have its roads in better shape than those of its neighbors.

The State commission is interested chiefly because it offers an opportunity to show the results of the indefatigable efforts of the road builders during the past few years in the interest of good roads.

Specimen of Long Island Road for a Part of the Way over which the Tour Trudged

In Lively Run L. I. A. C. Wins From C. A. C.

(*Continued from page* 951.)

The whole course was about 240 miles. All contestants checked in at the various controls within the time limits set and when the cars had finished at the Bay Ridge clubhouse of the Crescent Athletic Club and the cars had been turned over to the contest committee it was found that the Long Island Automobile Club had won by a good margin. The average penalty of each of the cars entered in that team was nine points, while those of their opponents totaled 168 or an average of 11 2-3 points per car.

At one of the Controls, the Automobiles Parked for the Time and the Contestants Enjoying Life

The possession of the Pardington cup is thus given to the L. I. A. C. for this year.

There was not an accident during the run and the best of feeling was apparent in the little brushes indulged in.

Those who represented the L. I. A. C. on the run were as follows:

C. W. Caffrey, Stoddard-Dayton; F. H. Evans, Franklin; Joseph D. Rourke, Haynes; Charles J. Banta, Speedwell; Alfred Wilmarth, Velie; Guy Loomis, Fiat; V. F. Parker, Simplex; Charles Hewlett Stevens-Duryea; Charles Werner, Locomobile; Albert Bryant, Overland; H. Grattan, Pope-Hartford; J. P. Disbrow, Rainier; A. W. Swanstrom, Chalmers-Detroit; C. H. Humphreys, Maxwell; M. Speiro, Pope-Hartford; L. R. Adams, Stearns; A. C. Alderman, Knox, and Jeremiah S. Frazee, Rambler.

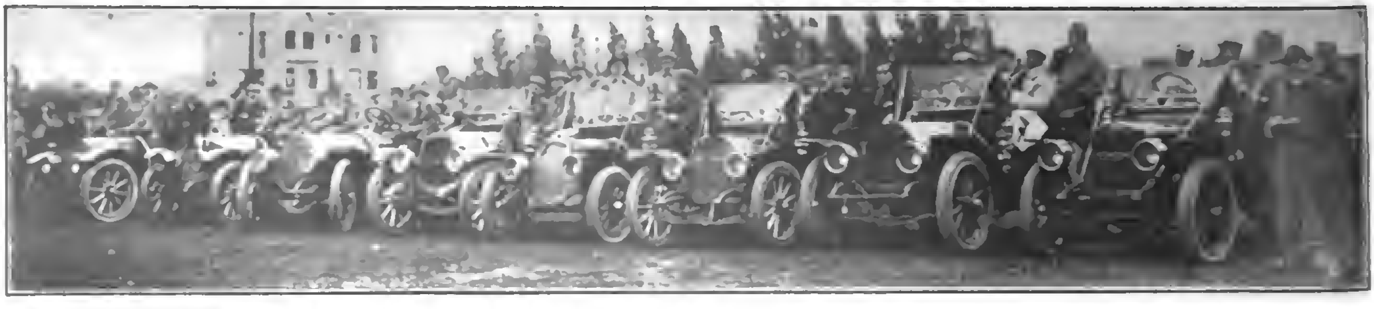
The Crescent Athletic Club team was composed of the following:

Foster Crampton, Peerless; George Brower, Franklin; Kingsley Swan, Stearns; Frederick Whitney, Locomobile; J. S. Masterson, Chalmers-Detroit; A. P. Palmer, Palmer-Singer; A. W. Blanchard, Herreshoff; S. C. Kirkman, Columbia; C. V. Bossert, Mercedes; W. C. Candee, Stoddard-Dayton; T. A. Buys, Oakland; J. I. Grady, Cadillac; G. F. Deely, Berkshire; G. Stephenson, Peerless; P. N. Bainbridge, Locomobile; J. P. Fairchild, Locomobile; Frank B. Stephenson, Peerless; A. R. Pardington, Chalmers-Detroit; H. C. Martin, Peerless.

Good Roads Tour Enthuses South

Swinging northward on its return trip to New York after exploring a route to be followed in June by the Atlanta-New York good roads tourists, the Columbia pathfinder has made excellent progress. Heavy rains below Roanoke, Va., made the going poor during one day last week, but in the main the trip across the Blue Ridge and Alleghanies was accomplished satisfactorily when the muddy roads are considered. Entries to the number of forty-one have been formally made and many others are being prepared. The entry box remains open until June 1. Mayor William J. Gaynor, of New York, has accepted an invitation to welcome the cavalcade when it appears at the water gate of the metropolis and has agreed to deliver the address of greeting.

In securing the consent of His Honor to officiate, the fact was brought out that the good roads movement in the South has resulted in the expenditure of over $18,000,000 for road improvement and steel bridges since the vogue of motoring swept that section. It was pointed out to Mayor Gaynor that the convicts of Georgia at present are making ten miles of good roadway every day of the year.



The "Muster" at which Thirty Automobiles Reported Present or Accounted for.

Callan Bill Passed Up to Governor Hughes

By a decisive vote, the Callan automobile bill was passed by the New York Assembly Monday night and is now lying upon Governor Hughes' table awaiting official approval. The bill was sharply fought in certain particulars and in its present shape represents a series of compromises, some of which are agreeable to motordom and some are not. The measure provides for a speed limit of fifteen to thirty miles an hour and for annual registration, the fees for which are scaled to correspond with the horsepower of the automobiles so registered.

One of the features that was eliminated from the original bill as passed by the Assembly was the provision to allow small cities and villages the right to regulate the speed of automobiles. This section was fought desperately by motorists all over the State, and the Senate finally passed an amendment taking the power to hamper automobilists by local regulations out of the hands of the small towns.

In a brief way the new law provides the following rules for motoring: A speed limit of thirty miles an hour on any State highway. Only one license number, which must not be allowed to swing, but which must be displayed both front and rear and must be illuminated in the rear and easy to read at all times. Drivers must be at least 18 years old unless accompanied by a licensed chauffeur. The speed limit in the larger cities may be fifteen miles an hour.

License numbers must be carried on plates fifteen inches long by six inches high and the letters must be four inches high.

The horsepower tax will raise the cost of New York registration from $1, as it is at present, to from $5 to $20 a car, depending upon the power of the automobile. Under twenty-five horsepower, the fee will be $5 and ranges upward until the maximum fee is charged for cars having more than fifty horsepower.

The Callan bill makes it a felony, punishable by a fine of $500 and imprisonment for not more than two years, for a chauffeur to run away after an accident in which his car has injured anybody. Driving while intoxicated is made a misdemeanor and on second offense, the driver may be imprisoned for from one to five years.

The victory of the motoring interests in preventing the possibility of heavy, restrictive regulation by small cities has been a source of satisfaction to motordom generally. Pressure was brought to bear upon the members of the upper house from all sides. The Long Island Automobile Club was particularly active in this matter and was the scene of a number of spirited meetings during the pendency of the bill. The result was the introduction of an amendment that passed the Senate without much difficulty after the members of that body had been duly impressed with the spirit of justice that actuated the motorists.

The Assembly already had passed the bill in its original shape and some opposition to the Senate amendment was feared in the lower house, but missionary work had been effectively applied there also and the popular body concurred in the amendment with only slight opposition.'

The clauses in the bill that were opposed by motorists were particularly the horsepower fee system and the chance given under the original bill for annoyance to tourists in small towns.

Coming Events in the Automobiling World

June 20-July 6....Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.

Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 13-25, 1911..Chicago Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

May 27, 28-30....Indianapolis, Ind., Automobile Races, including Championship Events on Motor Speedway.

May 28...........White Plains, N. Y., Hill-Climb under auspices of Amateur Automobile Contest Association.

May 30...........Fairfield, Conn., Hill-Climb under auspices of the Bridgeport Automobile Dealers' Association.

May 30...........Oklahoma City, Okla., Reliability run under auspices of the "Daily Oklahoman."

May 30...........Bridgeport, Conn., Hill-Climb up Sport Hill, Automobile Club of Bridgeport.

June 2...........New York City, N. Y., Trade Association, Orphans' Day Excursion to Coney Island and Return.

June 4...........Worcester, Mass., Fourth Annual Hill-Climb, Dead Horse Hill.

June 6-14........Atlanta, Ga., Reliability Run to New York City, New York Herald and Atlanta Journal.

June 7...........New Haven, Conn., Hill-Climb up Shingle Hill, Yale University Automobile Club.

June 11..........Wilkesbarre, Pa., Annual Hill-Climb up Giants' Despair, Wilkesbarre Automobile Club.

June 14-15.......New York, Reliability Run of Motor Contest Association.

June 14-30.......Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, Through the Southwest.

June 16-22.......Albany Automobile Club, Albany, N. Y., Sixth Annual Tour to Atlantic City and Return.

June 18..........Baltimore Hill-Climb of Automobile Club of Maryland.

June 25..........Port Jefferson, Long Island, N. Y., Hill-Climbing Contest, Automobile Club of Port Jefferson.

July 4...........Indianapolis, Ind., Cobe Trophy Race. Held on Speedway Track, Chicago Automobile Club.

July 4...........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

July 18-22.......Milwaukee, Reliability Run, Wisconsin State Automobile Association.

July 30..........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

Aug. 3-5.........Galveston, Tex., Beach Races, Galveston Automobile Club.

Sept. 5..........Wildwood, Pa., Speedway, Labor Day Race Meet of North Wildwood A. C.

Sept. 17.........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.

Sept.............Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

Oct. 1...........Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.

Oct. 8...........Philadelphia, Fairmount Park Race, Quaker City Motor Club.

Oct. 15..........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.

May 29...........Copa Catalunya, Voiturette Race of the Royal Automobile Club of Spain, near Barcelona.

June 2-8.........Prince Henry (German) Touring Competition.

June 13-18.......Scotland, Scottish Reliability Trials.

June 20..........French Voiturette Race.

June 21..........French Stock-Car Race.

June 22-July 5...Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.

June 27..........Speed Trials at Kiev, Russia.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

WHILE contests are the order of the day, and the automobile is putting its best foot forward in many such ways, it may not be out of place to call attention to the very nice arrangement which ended in enjoyment, nor is it too much to say, profit, which took the form of a two-day run on Long Island last Saturday and Sunday. The event which is the basis of editorial comment was run by the Long Island Automobile Club, collaborating with the Crescent City Athletic Club, but the matter here to be noted is based on the fact that the tour was one of leisure. Some of the contestants called it a "loafing tour," and it is to the credit of the sponsors of the run that they had the good sense to depart from the speed question just enough to give the participants the fullest opportunity to determine how nice it is to try the reverse to the usual methods. From what has been shown, it is believed that this tour, while it savored of a contest, was one of the most healthy and enjoyable events that was ever undertaken, and the L. I. A. C. is to be congratulated for having set the excellent example, which tells autoists that they do not have to go fast just because there are a lot of them in company.

⁂

AFTER struggling at first with the problem of getting up in the air the aeronautical world has now turned its best efforts toward solving the problem of getting back to earth with man and machine unharmed, and in these efforts it has been brought out that a motor of moderate weight working and obedient to throttle control affords more reassuring guarantees of a pleasant landing than the most ingenious wonder-engine capable of developing one-horsepower per pound but endowed with an instinct for spasmodic balking. Reliability looks "good" to a man whose frail frame is separated from the hard earth mainly by one mile of atmosphere; as indispensable as a featherweight engine formerly appeared to the designer who had not yet learned that free air only has to be tickeled in the right manner in order to be made to support heavy burdens with astonishing grace and ease. A rapid survey of the aviation-motor situation in Europe shows not only, however, that the early views with regard to the requirements for a combination of light weight and high power have been sobered, but also that much has been gained by the half-mistaken, previous demand for extraordinary lightness in motor construction. The slumbering designers were awakened and set about producing what they thought was wanted and, presto, it was discovered that the possibilities for refining the automobile motor had not after all been exhausted. A number of motors have seen the light of day, which were first made very light and afterwards quite reliable without losing much of their lightness, and these now bid fair to influence the design of motors for purely earthly roadways, where lightness over the front axle is also a quality of some economical value, particularly if it permits a corresponding lightening of the rear, now excluded by considerations relating to that distribution of weights which makes for the avoidance of slewing and safety in city traffic.

⁂

USED automobiles, after the original purchaser gets through with them, will still occupy space in garages or elsewhere, and they are likely to prove to be at least an annoyance to makers, if indeed they do not become a serious handicap of growing import, which will have to be coped with in the long run. In the meantime, to defer the evil day, is to teach the original purchasers how to retain the automobiles they acquire as long as possible. Weak minded individuals might consistently arrive at the conclusion that the sooner users discard cars they pay good money for, the better will they serve the industry from the point of view of makers. There is absolutely no basis for trade which may be regarded as healthy, if it has no better foundation than that involving the casting off of a device before it is worn out.

Of the total number of automobiles which reach the second-hand market within two or three years after they leave the makers' final test, nearly all of them are serviceable, but it is appearance that is against them. Then, too, they become noisy. This question of appearance is not merely tied up in the finishing problem; the bodies pass out of style. One of the first things to do in order to get more service out of an old car is to equip it with a new body; let the body be up to the times. It is much cheaper and better all around to purchase and pay for a new body than it is to abandon a good automobile for a new one, which, from the utility point of view, may not be very much, if any better.

Repair men, instead of confining their efforts to the mere process of replacing worn out parts, should pay more attention to the methods which will eliminate noise. An automobile may be capable of going and coming, but it may make too much of a fuss in the doing.

S. A. E. Succeeds Mechanical Branch of A. L. A. M.

President Coffin's Speech to Association Board

THE public is familiar with the aims, accomplishments, and character of the work formerly carried on by the Mechanical Branch of the Association of Licensed Automobile Manufacturers. Owing to the magnitude of the still fast-growing automobile industry, it is necessary that this engineering work be carried on, not only in accordance with the best methods that have obtained in every other industry of prime importance, but also in accordance with those conditions peculiar to the motor car business.

In no other industry has there been such development in such a short space of time. No other industry has given such economic value or has appealed so much to the element of personal interest upon the part of the average man. Methods long in use in the manufacturing arts have been revolutionized and new ones have been created to meet the demands of this wonderful age of mechanical transportation. If, in other great industries of the world, concerted work upon the part of engineers has been found necessary, then certainly it is of vital importance that the motor car engineers work hand in hand in the solution of those problems which fundamentally affect the future development of the automobile business.

The work of the A. L. A. M. Mechanical Branch was discontinued primarily for legal reasons having to do with the basic organization of what has now become the preponderating sales element in the automobile industry of America. At the last meeting of the Board of Managers of the Licensed Association, formal action was unanimously taken transferring to the Society of Automobile Engineers the data, records and goodwill of the Mechanical Branch. The society will continue the periodical publication of the specifications upon materials, prepared by Henry Souther and will carry on in a broader way much of the work begun by the Mechanical Branch. This action upon the part of the association is a short cut which will very materially favor the progress of the society's work in the simplification and solution of many of those difficulties which require concerted action upon the part of motor car engineers.

Howard E. Coffin, president of the Society of Automobile Engineers, in his address before the Licensed Association meeting, said:

"The Mechanical Branch, as you will recall, was discontinued, not because of any absence of the need for such an organization, but because of purely legal and business reasons. A good many suggestions have been made as to the possibility of a renewal of this work under the direction of the Licensed Association. But this is, I believe, impossible.

"It is superfluous to say anything to you as to the great need for concerted action on the part of our motor car engineers. Every purchasing department in the business is being seriously hampered in its work by the lack of uniformity in the material specifications, which are being passed on to them by our engineering departments. Every individual engineering department is a law unto itself in nearly all matters touching design and the preparation of specifications. Individuality of design is one thing and should be encouraged. Individuality in specifications is largely useless and should be restricted within reasonable limits. As a case in point, the engineering department of my own concern has lately delivered to our purchasing department material specifications upon which six months' delivery dates are the best promised. As a direct excuse for this delay the mills report their utter inability to care properly for the multitudinous and special demands which are being made upon them by motor car engineers. Among the similar situations which confronted the Mechanical Branch some three years ago was the question of steel tubing sizes and deliveries. The tube mills reported to our investigating committee not less than 1,600 different sizes of tubing which they were being asked to supply for the motor car trade. Few, if any, standard sizes could be stocked, because of the minute and immaterial differences in the specification in each individual case. The committee having this work in hand unearthed the further astonishing information that the specifications being turned in to the tube mills by individual automobile makers building only one or two models, covered not less than 80 distinct sizes or thickness of wall.

"With purchase orders in hand covering 1,600 different specifications through the comparatively limited range of the tubing diameters used in motor car work, it is small wonder that the expression of the tube mills' management to our committee was 'for God's sake, do something.' The net result of the Mechanical Branch work in connection with the tube mills will be found in a printed and framed table supplied to every engineering department within the association. In this table were listed something like 150 sizes of tubing actually needed in automobile work, and upon which practically immediate delivery was guaranteed by the mills.

"This tubing list again needs attention. The sheet metal situation is little better than was that upon tubing three years ago. There are a dozen other examples which might be cited, wherein standardization work would in no way affect individuality of design, but could lessen, the purchasing department problem.

"We see much in the press and in the advertising columns about the standardization of the modern motor car. There may be something in this term, if by it we mean that every car has a motor, a clutch, a transmission, a frame, springs and axles; but it is not any of these big generalities which cause us the trouble or which need standardizing. It is the little things—the little things which are different merely because they are different and for no good reason—which keep the purchasing departments in hot water and delay production. Nine times out of ten it is not the unavoidable act of Providence which delays the output—it is the irresponsible draftsman or designer who is permitted to draw upon his imagination for specifications throughout the entire range of theoretical possibilities. We need standard tables for reference in our engineering departments.

"The work of standardization in the specification of raw materials was only one of the several approved activities of the Mechanical Branch. Every other industry in the world of one-half the magnitude of the motor car business has its engineering organization, to which may be referred the innumerable problems requiring some concerted action upon the part of its engineers and designers. There is at the present time in this country only one organization which can be made to serve the very serious needs of the automobile industry. The Society of Automobile Engineers was formed about four years ago. The lack of a proper support of this organization by many of the engineers of this country has been chargeable to several causes, notable among which may be cited the existence of the Mechanical Branch, and later the hope on the part of many of our leading engineers that the Mechanical Branch work might be again taken up under the auspices of the Licensed Association. Coker F. Clarkson has now been engaged as secretary and general manager of this society, and its work will be made a decided value, both to the individual member and to the motor car business as a whole. In the Mechanical Branch days, Mr. Clarkson, then acting as secretary, carried upon his shoulders the administration of that organization in all its details, and all of you are sufficiently familiar with his work to know how good it was."

Tire Men and Makers Will Wait

New York City, May 23—Builders of automobiles and tire manufacturers met in conference at the headquarters of the Association of Licensed Automobile Manufacturers Tuesday, and after a full discussion and consideration of the tire question as it affects the owner, dealer and the automobile manufacturer, decided that the situation, so far as it relates to the purchase and sale of tires, need not be so pessimistically considered as some recent reports would indicate.

In fact, a more optimisitic view can now be taken. The manufacturers of cars in America are not in the position where it is necessary for them at this time to contract for the next season's requirements of tires, and the rubber tire manufacturers seem to be able to handle the present situation along lines that are expected to be in favor of the car owner.

There seems to be an impression that it is necessary for car owners to purchase tires for future use, due to the feeling that there is to be an abnormal advance on this particular product in the near future. While some increase may be expected, car owners should understand the conditions of buying now, and be warned of the disadvantages that might occur in purchasing in advance of current needs. There is hardly any question that the saving at the present time will be largely offset by the deterioration in surplus tires and the passing of the guarantee period.

It was the opinion of the conference that the interests of all will be served by a normal attitude toward future requirements.

All the prominent tire makers were in conference, numbering ten or a dozen, while those representing the Association were: Albert L. Pope, Chairman; L. H. Kittredge, S. D. Waldon, J. W. Gilson, Horace DeLisser and Alfred Reeves, General Manager.

Motordrome Plans Take Shape

With the purchase of 663 acres of land at Clementon, N. J., by the Philadelphia Motordrome Association, plans for the erection of a two-mile automobile speedway in the East have taken definite shape. Clementon is thirteen miles from Philadelphia and is crossed by seven state roads

The concern is incorporated under the New Jersey laws with a capitalization of $2,000,000, and some of the men connected with the project are, S. Boyer Davis, secretary and counsel of the Automobile Club of Philadelphia; A. C. Patterson, H. B. Reed and L. Kuehnle, bankers of the Quaker City.

New Jersey 15-Hour Endurance Run

Newark, N. J., May 25.--Eighteen entries have been made so far for the fifteen-hour endurance run to be given by the New Jersey Automobile and Motor Club on June 11. Full thirty cars are expected to compete. The entries so far in lude a Stoddard-Dayton, three Maxwells, two Mercedes, two Cadillacs, two Hupmobiles, Marmon, Overland, Marion, Auburn, Ford, Paterson and a Buick.

U. S. Motor Company Building

Detroit, Mich., May 23—Details of the United States Motor Company's plans for the development of its Detroit properties were made known to-day by Frank Briscoe. Work on the new buildings has started. A small army of men are breaking ground for the Alden Sampson plant, just north of the Brush. This plant will comprise six large buildings.

Within a month ground will be broken for a new plant for the Briscoe Manufacturing Company. This concern employs 1,500 and occupies an extensive plant at Woodward and Baltimore avenues, where it manufactures auto parts and accessories. On the completion of the new structure, to be erected immediately south of the Brush plant, the old one will be devoted exclusively to the manufacture of radiators.

An extension to the Brush factory will be built, work to start July 1. This will take up the remainder of the 50 acres owned by the Brush.

"There will be another group of buildings in some other part of the city," said Mr. Briscoe. "In the other group, in all probability, will be the new plant of the Gray Motor Company. Plans for the puıchase of more land are brewing.

Entries Revised to Date for the Glidden 1910

That the "National Reliability Run" will attract the notice of makers of automobiles is proven by the number of makes of machines which are officially entered. The list, to date, includes 11 automobiles in the "Glidden Trophy Division," 11 in the "Chicago Trophy Division," 8 in the "unclassified" list, and 3 in the "Non-contestant Division." The list complete to May 23, stands as follows:

Entries 1910 National Reliability Tour

Glidden Trophy Division

1 Premier Motor Mfg. Co.
2 Premier Motor Mfg. Co
3 Chalmers Motor Co.
4 Chalmers Motor Co.
5 Chalmers Motor Co.
6 Cole Motor Car Co.
7 Maxwell-Briscoe Motor Co.
8 Cartercar Company.
9 Parry Auto Co.
10 Bartholomew Company.
11 Staver Carriage Company.

Non-Contestant Division

Two Cadillac Gun Carriages entered by the North Western Military Academy.
Truck entered by the Rapid Motor Vehicle Co.

Chicago Trophy Division

100 Moline Auto Co.
101 Moline Auto Co.
102 Moline Auto Co.
103 Lexington Motor Car Co. (John C. Moore).
104 Cole Motor Car Co.
105 Parry Auto Company.
106 Fal Motor Car Co.
107 Maxwell-Briscoe Motor Co.
108 Cartercar Company.
109 Cartercar Company.
110 Lexington Motor Car Co.
111 Staver Carriage Company.

Unclassed

(It has not yet been decided in which division these entries will compete.)

2 Buicks.
2 Oaklands.
2 Pullman Motor Car Co.
2 Ohio Motor Car Co.

The fear is that some of the makers of high-priced automobiles will not see their way clear to go in; they seem to be laboring under the impression that the country through which the tour is to be made will not prove efficacious from their point of view. What every maker wants is sales; if they are not in prospect, interest languishes.

Itinerary of the National Reliability Tour

Leaving Dates A. M.	Starting Points.	Intermediate Stops.	Miles.	Finishing Points.	Day's Miles.	Arrival Dates. P. M.

Sixteen running days, average per day, 178.2 miles.

Chicago Motor Club Economy Run Finished

CHICAGO, May 23—Probably no other fuel test ever held in this country was run so true to actual touring conditions or showed as much as did the one promoted by the Chicago Motor Club yesterday, which was won by a Cole 30 driven by A. W. Johnson which averaged 23.6 miles per gallon and gained a percentage of 2.8 over a route 191 miles in length, which had Lake Geneva for its turning point. Because of the long distance of the run and the varying conditions of the highways and the necessity of maintaining the fast schedule provided for by the A. A. A. rules, there was nothing artificial about the test. Carbureters had to be tuned up to meet all conditions, therefore it was impossible to starve the carbureter in order to save gasoline. The DeTamble, a two-cylinder proposition, was the only one which had to do 16 miles an hour, the others being called upon to show 18 and 20. Yet notwithstanding this, all the cars with but two exceptions met the time requirements, which makes the fuel economy showing all the more remarkable. Up around Lake Geneva it was distinctly hilly, and while some of the drivers had to shift gears on grades that ordinarily they would take on high, yet they all kept up to the schedule with great ease. The Overland and Grout were the only ones that did not get in on time.

Originally there were thirteen entries for the trial, but owing to a bad spell of weather two postponements were necessary, and instead of running the affair on April 28 it was May 19 before the event came off. Because of this delay, the Franklin, Moon, Oakland and Welch were scratched, leaving the DeTamble in class 1A, the Hupmobile and Overland in 2A, the Cole and Hudson in 3A, the Falcar and Henry in 4A, the Grout in 5A, and the Knox in 6A, to make the circuit. The Henry got no farther than Maywood on the first leg, where it retired because of magneto trouble. The other side of Elgin the Knox had tire trouble and running out of its supply of inner tubes, it was necessary to lay up along side the road until a fresh supply could be obtained from Lake Geneva. This made the Knox 7 hours and 32 minutes late at the finish, but as time out was allowed for tire trouble the judges gave it a rating, placing it second. Besides wresting with tires, driver Bender was also handicapped by losing the course at Lake Como, and going 8 miles out of his road. This, however, was not recognized by the judges, and his fuel consumption was reckoned as if he had only made 191 miles.

H. E. Halbert driving the Grout, also experienced roadside difficulties but coped with them in a game manner which won him considerable recognition. On the return journey from Lake Geneva, Halbert found he was unable to shift gears, and in an examination disclosed that a steel pin had dropped into his gears and chipped off some of the teeth. To remove this cotter pin he had to take down the entire transmission. Despite this handicap he got going again and finished, but was one hour behind his schedule time so the judges were compelled to disqualify him. The Hudson and the Falcar both broke leaves in the front springs, but luckily for the drivers they were able to make temporary repairs, and get in on time. The Overland was not so fortunate, its broken spring making driver Schillo 20 minutes late, which brought about the disqualification of the car. If the Grout had not been behind time, it would have been

Fig. 1—Typical road scene during the economy run near Algonquin

Fig. 2—Hupmobile, at a point near Lake Geneva, on the run

ranked fourth in the final round up with a percentage of 2.31 and a showing of 14.5 miles to the gallon. The Overland would have been fifth with 1.915 and 17.09 miles to the gallon.

The DeTamble also was handicapped by an obstruction in the gasoline feed pipe, and driver Turgeon had to make at least a dozen stops, remove the pipe each time and blow through the tube. Then he would couple it up again, and resume his journey. In this manner he swung around the 191 mile circuit and got in on time.

A most creditable performance was put up by E. A. Hearne driving the Hupmobile, which carried off the honors in straight fuel consumption, Hearne getting 25.8 miles to a gallon, which was considered remarkably good by those who know the severity of the route and the hills encountered in Wisconsin. Hearne also was bothered some by a feed pipe obstruction, and had to open up his carbureter more than would have been necessary had the line been clear.

In addition to the main prize, a silver trophy certificate of performance were awarded the winners of the various classes. Those to get these diplomas were the DeTamble in Class 1A, the Hupmobile in 2A, the Cole in 3A, the Falcar in 4A, and the Knox in 6A.

Score of the Cars in the Run

Car.	H.P.	Class.	Driver.	Ounces of gas.	Miles per gal.	Weight.	Percentage.
Cole	30	3A	W. A. Johnson	1036	23.6	2950	2.8
Knox	40	6A	J. A. Bender	1761	15.6	4255	2.72
Hudson	22	3A	James Levy	1146	21.34	2780	2.42
Falcar	28	4A	C. F. Van Sicklen	1780	13.7	3390	1.904
Hupmobile	17	2A	E. A. Hearne	947	25.8	1640	1.73
De Tamble	14	1A	G. W. Turgeon	1351	18.1	1970	1.45
Grout*	36.6	5A	H. E. Halbert	1683	14.5	3900	2.31
Overland*	22	2A	A. G. Schillo	1295	17.09	1295	1.915
Henry	27.2	4A	E. C. Haynes	Did not finish.			

*Disqualified for finishing outside time limit.

Norristown Reliability Run

(*Continued from page* 955.)

According to the announcement, Youngs' Selden captures the MacDonald & Campbell Class A trophy, a handsome $350 8 ft. high grandfather's clock; Walls' Maxwell the McCullough Class B prize; Hardesty's Pullman the Kelly-Springfield, Class C emblem, and Fairlamb's Kline-Kar the Class D plaque hung up by the Norristown Chamber of Commerce. There was some talk about the hotel to-night, however, of several protests being filed, mainly on the grounds of misinterpretations of the rules by the technical sharps. The Kline-Kar men aver that a strict interpretation of the A.A.A. rules would put their car ahead of the Selden in Class A. There is but 6 points difference and the "brush" was correspondingly interesting.

1910 Blue Books Are Fresh From the Press

Just in time for the opening of the touring season, the four volumes of The Automobile Blue Book are fresh from the press; they cover situations as follows:

Volume No. 1

New York State complete, including all the passable roads through the Adirondacks, lower Canada, including three routes between Niagara Falls and Toronto to Detroit (Windsor) and Port Huron (Sarnia) Erie to Lake Huron and trunk lines to the Middle West.

This section will contain over 800 pages, an increased number of city and route maps and directions for approximately 40,000 miles of highway.

Volume No. 2

New England, covering New Hampshire, Vermont, Maine, Massachusetts, Rhode Island and Connecticut, with extensions itno the Canadian provinces. The Red Book Automobile Guide has been consolidated with this volume and the purchaser of this section has all the information heretofore contained in two books. This volume covers a most beautiful touring section of the country, including the White Mountains and the Maine Woods.

Volume No. 3

New Jersey, Pennsylvania, and South, including Maryland, with the extension routes into the Virginias, Carolinas, Georgia and Florida. This section takes the tourist to all the popular seaside and mountain resorts, and the historic battlefields of the South, districts replete with touring interest.

This section will contain over 750 pages, an increased number of city and route maps and directions for about 27,000 miles of highway.

Volume No. 4

The Middle West with through lines to Omaha and Kansas City. There are 350 routes with a total of 35,000 miles, more than double that of last year.

An Efficient Book For the Busy Roadbuilder

In road engineering the latest word is the best, and it comes from a reliable and well-informed source, since all conscientious road builders are anxiously compiling knowledge which will permit them to meet the new road requirements which automobile traffic and the increasing demand for luxurious intercommunication between city and country have called into existence. This latest but not last word is given in "Dust Preventives and Road Binders," a new book by Prévost Hubbard, which places at the disposal of the road engineer practically all the facts which have been ascertained at the Department of Agriculture in Washington on the subject of materials for modern roads and the best methods for distinguishing between good, bad and indifferent, not only in the materials offered the road builder in commerce but also in the ways of using these materials. As chemist in the Office of Public Roads in Washington and secretary of the committee on road materials of the American Society for Testing Materials, the author has had practical as well as laboratory experience with all varieties of road binders under varying conditions in many parts of the United States, and it is the information and insight gained through this work which he now places at the disposal of others. Many of the bituminous hydrocarbons used as binders lose a considerable percentage through the evaporation of volatile constituents, and the loss leaves the residuum too brittle for its purpose. The methods outlined by the author for determining the fitness of these and other materials are given with such completeness as to be of especial value to the technical reader, and while the penetration treatment of old roads largely employed in France and England, where the question of new construction does not arise so frequently, has not been treated as exhaustively as the mixing system, descriptions and illustrations of the machines employed abroad for forcing coal tar or water gas tar into the roadbed by means of pneumatic nozzles supply a line of information which will be highly appreciated in many progressive quarters. Published by John Wiley & Sons, New York, and Chapman & Hall, Limited, London.

New French Rating Formula Considers Stroke

(*Continued from page 965*)

As a source of comparison of all formulas now in use, a review of all the formulas given in a recent issue of *Machinery* by Mr. E. Hubendick is given herewith. In these formulas, the characters in common use will be employed as follows:

D = diameter of cylinder,
N = number of cylinders,
S = length of stroke,
n = number of revolutions per minute.

The French Automobile Club's formula is:

$H.P. = 0.07\,D^2N$, when the diameter is given in centimeters,

$H.P. = 0.45\,D^2N$, when the diameter is given in inches.

In this formula the mean pressure has been assumed to be 5.3 kilograms per square centimeter (75 pounds per square inch), and the piston speed 5 meters (16 feet 5 inches) per second.

The Royal Automobile Club's (British) formula is:

$H.P. = 0.0625\,D^2N$, when the diameter is in centimeters.

$H.P. = 0.405\,D^2N$, when the diameter is given in inches.

Mr. Arnon's formula is:

$H.P. = 0.0061\,D^3N$, when the diameter is in centimeters.

$H.P. = 0.1\,D^3N$, when the diameter is given in inches.

Mr. Faroux's formula is:

$H.P. = 0.0074\,D^{2.4}\,S^{0.6}$, when the diameter is in centimeters.

$H.P. = 0.121\,D^{2.4}\,S^{0.6}$, when the diameter is given in inches.

Another French formula is as follows:

$H.P. = 0.02562\,D^{2.4}\,N$, when the diameter is in centimeters.

$H.P. = 0.24\,D^{2.4}\,N$, when the diameter is given in inches.

Mr. T. Thornycroft's formula is:

$H.P. = \frac{D^2\,S^{0.75}\,N}{35{,}000}$, when the diameter is given in centimeters.

$H.P. = \frac{D^2\,S^{0.75}\,N}{2{,}700}$, when the diameter is given in inches.

Prof. H. L. Callender's formula is:

$H.P. = 0.0875\,D\,(D - 2.5)\,N$, when the diameter is given in centimeters.

$H.P. = 0.565\,D\,(D - 1)\,N$, when the diameter is given in inches.

In this latter formula the mean pressure is assumed to vary in the same proportion as $\left(1 - \frac{2.5}{D}\right)$ if the diameter is given in centimeters, and $\left(1 - \frac{1}{D}\right)$ if the diameter is given in inches.

The Royal Automobile Club's (Swedish) formula is:

$H.P. = \frac{D^2SnN}{250{,}000}$, when the diameter is given in centimeters.

$H.P. = \frac{D^2SnN}{15{,}240}$, when the diameter is given in inches.

Licensed Automobile Manufacturers' formula is:

$H.P. = \frac{D^2N}{2.5}$, when the diameter is given in inches.

$H.P. = 0.062\,D^2N$, when the diameter is given in centimeters.

Glidden Tour and Hoosier Meet

ENTRIES for Glidden Tour may be made until June 1. The list will be closed, according to announcement made from A. A. A. headquarters.

Nearly all of the classes in the National Championship races, to be run on the Indianapolis Motor Speedway, May 30, are filled. Indications point to a very successful meet. Workouts have been begun by the National, Marmon, Fuller, Herreshoff and other cars entered.

In addition to the championship medals, several side trophies are offered by the Prest-o-lite and Wheeler and Schebler Companies. Entries for the championship races, embracing all divisions of stock cars in this year's contest rules, closed May 25.

Blanks Are Out for Quaker City Event

PHILADELPHIA, May 23—Blanks are out for the first of the Quaker City Motor Club's series of track races, which will be held June 4 at Point Breeze. The races will be Class C events, according to the new A. A. A. rules—Division 1, five miles, piston displacement 160 inches and under; Division 2, five miles, 161 to 230 inches; Division 3, five miles, 231 to 300 inches; Division 4, 10 miles, 301 to 450 inches; event 6, at 25 miles, will be open to Divisions 1, 2 and 3; event 7, at 50 miles, to Divisions 4 and 5. Indications are that the events will be well patronized. The club is schooled in work of this sort, and the event is looked forward to with interest by those who appreciate well-managed contests.

The Little Tots Were Taken for a Joy Ride

LAST week twenty-five owners of Stearns cars placed their automobiles at the disposal of Wyckoff, Church & Partridge, of New York, for the Fourth Annual Outing given to the pupils of the Free Industrial School for Crippled Children of West 57th Street.

A slight change was made in the program this year, the little ones being given the privileges of Dreamland by Mr. Gumpertz, the kind-hearted manager of that famous recreation resort.

The happy children were given badges and silk flags, stopping at Broadway and 56th Street long enough to be snap-shotted at that point, after which the parade continued down Broadway and Fifth Avenue, and across the new Manhattan Bridge, through Brooklyn and the shore drive to the ample grounds and club house of the Crescent Athletic Club at Bay Ridge, overlooking the bay.

Here a rest of two hours was taken to allow the pupils to romp on the grass and try out the toy aeroplanes which their hosts had provided for them. A liberal luncheon was served them in the club house jointly by the club and Wyckoff, Church & Partridge.

Continuing the trip the party, numbering about 120, arrived at Dreamland at 2 P. M., where all the various amusement features were thrown open to them through the liberality of Manager Gumpertz. The water chutes, Venice, the alligator farm, Bostock's animals, etc., received full patronage. Heretofore the rides have always terminated at Luna Park, the new attractions of Dreamland being distinct novelties this year for the entire party.

The reloading of the cars was begun at 4.30 P. M., the party starting for the Reisenweber's Casino on the Ocean Boulevard, where Manager Fischer served ice cream and cake to the ladies and children.

The return was made over the Williamsburg bridge, up Broadway, without a hitch, arriving at the school at about 6 o'clock. Each little tot, though tired and dusty, was happy and full of enthusiasm at the wonderful sights.

A perfect line was maintained throughout the entire trip, thanks to the kind help of Sergt. Casey and his aiders, Officers Howe, Faber and Culbertson, who accompanied the party throughout the entire day.

The ladies who accompanied the party were Mrs. Arthur Elliott Fish, Mrs. E. B. Archer, Mrs. M. E. Bullard, Miss Robin, Miss Demarest, Miss Wherry, Mrs. E. A. Hoffman, Mrs. J. E. Demar, Mrs. E. S. Partridge, Mrs. Williams and Mrs. Loomis.

Among those who kindly loaned their Stearns cars for the trip are Mr. Fred Stone, Mr. David Montgomery, A. W. Lesser, Aug. Luchow, Geo. H. Wumschell, Edgar Gibbs Murphy, Mr. McKeever, C. F. Wyckoff and others.

Weather conditions were perfect and the Stearns owners who loaned their cars were amply repaid for the small sacrifice when they saw the happiness this Annual Outing gave the children of the Free Industrial School.

Stearns Automobiles Assembled in Front of Wyckoff, Church & Partridge Broadway Establishment before the Start

Ready For Big Hoosier Races

INDIANAPOLIS, May 23—Everything is in readiness for the opening of the grand circuit automobile races on the Speedway Friday and Saturday, and the National Championship races, which will be held Monday.

Entries have been liberal in all the events listed on the program and a spectacular and successful meet is promised. The entries are as follows:

FRIDAY, MAY 27.

Event No. 1—Cars, class D—Record trials from ¼ mile to 1 kilometer. To lower world's speedway records. Free-for-all cars. Each car will be permitted to make two trials, electrically timed.

Event No. 2—Stock chassis cars, class B, division 1—160 cubic inches piston displacement and under. Minimum weight, 1,100 pounds. Distance, 5 miles.

Event No. 3—Stock chassis cars, Class B, division 2—161 to 230 cubic inches piston displacement. Minimum weight, 1,400 pounds. Distance, 5 miles.

Event No. 4—Stock chassis cars, class B, division 3—231 to 300 cubic inches piston displacement. Minimum weight, 1,700 pounds. Distance, 10 miles.

Event No. 5—Stock chassis cars, class B, division 4—301 to 450 cubic inches piston displacement. Minimum weight, 2,000 pounds. Distance, 5 miles.

Event No. 6—Stock chassis cars, class B, division 5—451 to 600 cubic inches piston displacement. Minimum weight, 2,300 pounds. Distance, 10 miles.

Event No. 7—Cars, class D—Free-for-all handicap. Open to all cars entered at this meet. Cars will be handicapped in accordance with their performances at this meet by the board of official handicappers. Distance, 5 miles.

Event No. 8—Stock chassis cars, class E—Open only to registered amateur drivers in accordance with definition of racing rules of the A. A. A. Distance, 5 miles.

Event No. 9—Cars, class D—Free-for-all open race. Distance, 5 miles. Conditions of deed of gift for the Indianapolis motor speedway helmet. This prize is to be competed for by free-for-all cars of class D. at the May, July, August and September meets, 1910. The winner of this race and the successive races for which this prize is offered, shall be entitled to $50 per week from Decoration day, May 30, until Thanksgiving day, 1910, provided he successfully defends and wins same at each meet. The speedway helmet is to be worn by the winner while defending same. In case of postponement or the declaring off of any of these meets, or discontinuing this event, then the last holder of this trophy shall receive the sum of $50 per week for 60 days after such notice has been published. The holder of this trophy at the end of the season is entitled to permanent possession of same.

Event No. 10—Stock chassis cars, class B, division 4—301 to 450 cubic inches piston displacement. Minimum weight, 2,000 pounds. Distance, 100 miles. For the Prest-O-Lite trophy.

SATURDAY, MAY 28.

Event No. 11—Cars, class D—Record trials for 1 mile. Free-for-all cars. To lower world's speedway records. Each car will be permitted to make two trials, electrically timed.

Event No. 12—Stock chassis cars, class B, division 4—301 to 450 cubic inches piston displacement. Minimum weight, 2,000 pounds. Distance, 10 miles.

Event No. 13—Stock chassis cars, class B, division 5—451 to 600 cubic inches piston displacement. Minimum weight, 2,300 pounds. Distance, 5 miles.

Event No. 14—Cars, class D—Free-for-all handicap. Open to all cars entered at this meet. Cars will be handicapped in accordance with their performance at this meet by the board of official handicappers. Distance, 10 miles.

Event No. 15—Stock chassis cars, class E—Open only to registered amateur drivers in accordance with definition of racing rules of the A. A. A. Distance 10 miles.

Event No. 16—Stock chassis cars, class B, division 6—601 to 750 cubic inches piston displacement. Minimum weight, 2,500 pounds. Distance, 5 miles.

Event No. 17—Cars, class D—Free-for-all open race. Distance, 10 miles.

Event No. 18—Cars, class E—600 cubic inches piston displacement or less. Minimum weight, 2,300 pounds. Distance, 200 miles. For the Wheeler & Schebler trophy.

MONDAY, MAY 30

Event No. 1—Stock chassis cars, class B, division 1—160 cubic inches piston displacement and under. Minimum weight, 1,100 pounds. Distance 5 miles.

Event No. 2—Stock chassis cars, class B, division 2—160 to 230 cubic inches piston displacement. Minimum weight, 1,400 pounds. Distance, 10 miles.

Event No. 3—Stock chassis cars, class B, division 3—231 to 300 cubic inches piston displacement. Minimum weight, 1,700 pounds. Distance, 5 miles.

Event No. 4—Stock chassis cars, class B, division 3—231 to 300 cubic inches piston displacement. Minimum weight, 1,700 pounds. Distance, 10 miles.

Event No. 5—Stock chassis cars, class B, division 4—301 to 450 cubic inches piston displacement. Minimum weight, 2,000 pounds. Distance, 5 miles.

Event No. 6—Stock chassis cars, class B, division 4—301 to 450 cubic inches piston displacement. Minimum weight, 2,000 pounds. Distance, 10 miles.

Event No. 7—Stock chassis cars, class B, division 5—451 to 600 cubic inches piston displacement. Minimum weight, 2,300 pounds. Distance, 5 miles.

Event No. 8—Stock chassis cars, class B, division 5—451 to 600 cubic inches piston displacement. Minimum weight, 2,300 pounds. Distance, 10 miles.

Event No. 9—Stock chassis cars, class B, division 6—601 to 750 cubic inches piston displacement. Minimum weight, 2,500 pounds. Distance, 5 miles.

Event No. 10—Cars, class D—Free-for-all open race. Open to all cars entered at this meet. Distance, 5 miles.

Event No. 11—Cars, class D—Free-for-all open race. Open to all cars entered at this meet. Distance, 10 miles.

Event No. 12—Cars, class D—Free-for-all handicap. Open to all cars entered at this meet. Cars will be handicapped in accordance to their performances at this meet by a board of official handicappers approved by the contest board of the American Automobile Association. Distance, 5 miles.

Event No. 13—Stock chassis cars, class B, division 3—231 to 300 cubic inches piston displacement. Minimum weight, 1,700 pounds. Distance, 50 miles, for the G & J trophy. Valued at $1,000. This event shall be competed for twice during the season of 1910.

Event No. 14—Stock cars, class E—For the John A. Wilson trophy. Valued at $150. Donated by John A. Wilson, of Franklin, Pa., to be awarded to the stock touring car that first makes a full mile in 1 minute or less under regular touring conditions and carrying four passengers; the contest to be confined to cars of not more than 50 horsepower, A. L. A. M. rating; regular touring bodies—not baby tonneaux or torpedo bodies—tanks full, top on but may be down; mud guards on and regular supply of tools; passengers to weigh not less than 160 pounds each and to sit upright in the car; to ensure there is no down grade, the mile to be made both ways of the track; if more than one entry in the contest, then the car making the fastest time to be awarded the cup, provided said fastest time equals a mile-a-minute.

N.Y. Taxicab Rates to Come Down

John Drennan, 74 West Eighty-ninth street, has been appointed taximeter inspector in New York under the provisions of the new law which goes into effect in sixty days. The law requires a maximum rate of thirty cents a mile for the first mile in a two-passenger machine and ten cents for each additional quarter mile with $1 an hour for waiting time.

The four-passenger machines may charge forty cents a mile for the first mile and ten cents for additional quarters with waiting time of $1.50 an hour. Hand baggage is free and so is the transportation of children under the age of five years. It will be part of Mr. Drennan's duties to inspect the mechanism of the meters and if they should prove to be too fast, the law provides heavy penalties. It is expected that this new plan will work to the entire satisfaction of the patrons of taxicabs.

Reo Wins Cup in Drawing Straws

RICHMOND, VA., May 25—Drawing straws was resorted to to determine which of the four cars that finished the Virginia Endurance Run with clean scores should gain possession of the cup offered as first prize. The Reo, driven by F. E. Nichols, was the lucky one, but the names of the three losers will be engraved upon the cup and each will receive a class cup. Miss Anne Dunlop, the only woman to take part in the race, was given a special prize for driving her car, a Maxwell, from start to finish without masculine assistance.

More Autos for the Orphans

One hundred more cars are needed by the Orphans' Day committee in order to make the annual celebration in New York an unqualified success. More money is also required, although contributions are coming in at a good rate.

Edward Steindler has donated the use of four sight-seeing automobiles, and during the past week many owners of private cars have offered them to the committee. Half a dozen great trucks have been given to the committee for the occasion and the motor wagon division will be notably large.

Races Likely at Lowell This Fall

BOSTON, May 23—The committee on roads and bridges of the Massachusetts legislature this afternoon voted to report the bill allowing the selectmen of Tyngsboro and the aldermen of Lowell to close the roads in that vicinity when necessary between Sept. 15 to 22 next in order that there may be more automobile races.

Now that the bill has been reported to the legislature, it is expected that Senator Hibbard will push it along, and then the Lowell men will get busy arranging for the race with those who are going to put it on.

Delaware Club to Tour June 18

WILMINGTON, DEL., May 23—The executive committee of the Delaware Automobile Association, at a meeting held this evening, decided to have the annual roadability run June 18, but as several routes have been suggested by the pathfinding committee, the matter of selection of the route was left open for a few days.

This is likely to be the only big run of the year for the Delaware Club, and the indications are that it will attract probably 50 entrants.

At the executive committee meeting a request was received from Rev. D. M. Cleland, pastor of the United Presbyterian Church, this city, for the co-operation of the members in a proposed automobile outing to poor children of the city on June 10, and the committee agreed to co-operate. It is expected that from 75 to 100 cars will be required.

"Lady Overland" at Cleveland

CLEVELAND, May 23—In excellent condition, the Overland car, bearing Miss Blanche Stuart Scott and a woman friend reached this city Sunday night after accomplishing the first leg of the transcontinental tour to San Francisco.

Miss Scott was accorded hearty receptions all along the way, particularly so at her home city, Rochester. The weather has been trying so far for heavy rains have fallen frequently, making ordinarily good roads quite boggy and uncertain. Through the Mazuma swamps, near Syracuse, chains had to be used constantly. The only troubles encountered so far have been carbureter difficulties and two punctures. The car left for Erie Tuesday morning and is scheduled to arrive at Cleveland this afternoon. A number of entertainments have been arranged for the tourists in the Forest City and they will remain there for two days.

Buffalo Club Increases Activity

The Automobile Club of Buffalo will conduct, during this summer, a four, or five days' reliability touring contest of not less than two hundred miles each day, starting and finishing each day at Buffalo.

Make Parts and Accessories

INDIANAPOLIS, May 23—The Pyle Spring Tire Company, of this city, and the Bimel Spoke and Auto Wheel Company, of Portland, have been recently organized. The former has a capitalization of $50,000, and will make a spring tire and motor parts for the trade.

The latter concern has $100,000 capital, and will manufacture spokes and wheels of an advanced type. Both companies plan to enter business actively in the immediate future, employing full forces of men.

South Stirred by Carolina Run

RICHMOND, VA., May 23—Few occurrences in automobile circles of Virginia or North Carolina have attracted as much interest as the approaching Carolina Endurance Run. The run will be held on June 7, 8, 9, 10, 11, and the course will be as follows:

First Day—Richmond to Littleton, N. C., by way of Petersburg and Emporia.

Second Day—Littleton to Raleigh, by way of Warrenton, Henderson and Wake Forest.

Third Day—Raleigh to Clarkesville, by way of Apex, Durham, Chapel Hill and Oxford.

Fourth Day—Clarkesville to Richmond, via the old Boydson plank road, Boydson and Petersburg.

The run is being given by the *Times-Dispatch* of Richmond, in the interests of good roads. It is under the rules and auspices of the American Automobile Association, members of which will be present and traverse the route.

Entries for Good Roads Tour

Forty-three entries to the Atlanta-New York tour under the auspices of the New York *Herald* and Atlanta *Journal*, have been received up to May 25. The box closes June 1.

OFFICIAL CARS (NON-CONTESTING)

Entrant's Name and Address	Make of Car
R. H. Johnston, the White Company, New York	White Steamer
Matheson Automobile Company, New York	Matheson "Silent Six"
Ray M. Owen, for R. M. Owen & Co., New York	Reo Roadster
Columbia Motor Car Company, New York	Columbia
James R. Gray, Atlanta	Pierce-Arrow
Ajax-Grieb Rubber Company, New York	Lozier (Briarcliff model)

CONTESTING ENTRANTS

Beaumont Davison, Atlanta	Packard
W. J. Stoddard, Atlanta	National
Colonel J. J. Woodside, Atlanta	Thomas
R. E. O'Donnelley, Atlanta	Packard
Joseph F. Gatins, Jr., Atlanta	Knox
Edward M. Durant, Atlanta	Pope-Toledo
W. S. McNeil, Jr., Atlanta	Lambert
Regal Motor Car Company, Detroit, Mich.	Regal
W. T. McNinch, Atlanta	Lambert
Atlanta Motor Car Company, Atlanta	White Star
Jackson P. Dick, Atlanta	American Traveler
Maxwell-Briscoe Motor Company, New York	Maxwell Touring Car
Edward H. Inman, Atlanta	Simplex
C. W. Dupre, Marietta, Ga	Maxwell
Charles I. Ryan, Atlanta	Columbia
W. E. Wimpy, Atlanta	Buick
J. H. Marsteller, Roanoke, Va	Chalmers-Detroit
Forest Adair, Atlanta	Stevens-Duryea
E. M. Willingham, Atlanta	Ford
N. W. Wallace, Charlotte, N. C	Hupmobile
P. S. Arkwright, Atlanta	Pope-Hartford
A. Burwell, Jr., Charlotte, N. C	Firestone-Columbus
Brush Automobile Company, Atlanta	Brush
Kelly-Knight Motor Car Company	Kissel-Kar
Arthur T. Smart, Atlanta	Speedwell
Georgia Motor Car Company, Atlanta	E-M-F
Mrs. Elizabeth A. de Giers, New York	Thomas
E. D. Crane & Co., Atlanta	Firestone-Columbus
W. D. Alexander, Atlanta	Stoddard-Dayton
Asa G. Candler, Jr., Atlanta	Lozier
Maxwell-Briscoe Company, Tarrytown, N. Y	"Baby" Maxwell
John W. Grant, Atlanta	Locomobile
E. D. Crane & Co., Atlanta	Hupmobile
T. H. Cooper, Salem, Va	Corbin
C. H. Johnson, Atlanta	Stevens-Duryea
Georgia Commission Company, Albany, Ga	Halladay
John Moore & Co., New York	Brush

The cars will be divided into seven divisions or classes, regulated by their prices, under A.A.A. rules.

A silver cup is offered to the winner of each class, while a large silver cup, engraved with the name of the contest, is up as the sweepstake prize, and will go to the winner over all divisions, which has the cleanest score.

About thirty entrees are expected for the run.

Prepare Tour Around Long Island

All around Long Island will be the course of the two-day reliability tour which will be run June 14-15 under the auspices of the Motor Contest Association. The course will be about 200 miles the first day, starting at the western end of the Island and traversing it to Montauk Light, with night control at Orient Point. The second day's route will generally follow the North shore. The cars will run in two divisions, one for contestants and the other for amateurs. Twenty-five prizes have been offered. The run is sanctioned by the A.A.A. The pathfinding car in charge of Raymond Beck left last Saturday to pick out the route.

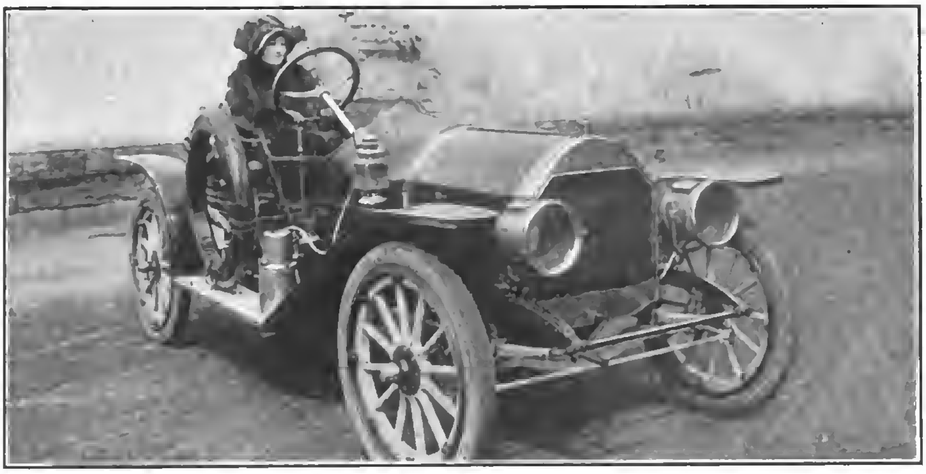
Star Pathfinder Has Rough Trip

ST. LOUIS, May 23—The Buick pathfinder "Red Wing" (Model 17), sent out by the St. Louis Automobile Manufacturers' and Dealers' Association to chart a route for the Star trophy finished its trip Saturday, arriving in St. Louis at 12.30 p. m. The car, in five and a half days made more than 500 miles, much of the distance through mud, which it was almost impossible for a team of mules to pass through safely, and the car was stuck only once and stopped only once for repairing. The route was a circuit of Northeast Missouri and Eastern Central Illinois.

DETROIT, May 23—Organization of the Gaylord Motor Car Company has been perfected in Gaylord, Mich., and the company has engaged Guy Hamilton, of this city, to act as manager. Mr. Hamilton is now making arrangements for the purchase of machinery and other equipment for the factory. Construction work will begin at once. The new company is capitalized at $100,000.

The company, it is learned here, will manufacture an entirely new type of car, designed especially for the use of farmers, and one that will take readily to the country roads. It is also planned to manufacture a farm truck which the farmer may use in hauling his produce to market.

The Regal Motor Car Company, of this city, is ready to start work on its Canadian branch in Windsor, Ont., as soon as the taxpayers of the municipality vote on the question of selling the company the site.



Cole "Thirty" known as a Torpedo Roadster as it appears on the highway

In the Realm of the Makers

The Ramsay - Alton Manufacturing Company, of Portland, Mich., has decided to manufacture auto tops. J. Hayes, of Detroit, has invested $10,000 in the new enterprise, which is expected to give employment to about fifty men.

Plans are being prepared for the erection of a large plant by the Sommer Motor Car Company at Bucyrus, O. L. A. Sommer is president of the concern, which will make several types of motor cars. It is expected to have the plant completed by fall.

Findlay, O., is to have a third automobile plant. L. E. Ewing, of Cleveland, a few days ago purchased the North Side plant of the Findlay Axe & Tool Co., which will be converted into a motor car factory as soon as the building can be prepared for it. Present plans contemplate the organization of a company capitalized at $300,000.

The E-M-F factory announces that it will establish a branch in Omaha and will start construction at once on a new building. N. P. Bergers, of the Bergers Automobile Company, which has been handling the E-M-F cars, will be the Nebraska and Iowa manager. It is planned to build a large two-story structure with garage, showroom, repair shop, etc. Manager Bergers is now looking for a site.

The Briggs & Stratton Company, of Milwaukee, has just completed its new plant. The building is of concrete construction, fireproof, and is equipped with everything in the line of modern machinery and tools to make the B. & S. igniter. In addition to the equipment of special tools and machinery for manufacture of the mechanical parts, a complete vacuum impregnating apparatus for the special treatment of spark coils has been installed.

The Electric Goods Mfg. Co., of Canton, Mass., is offering fifty $10 prize cups free to motorboat clubs if the clubs will enter into a contest involving "Prefex" Ignition System, in such a way as to bring out the waterproof qualities of same in comparison with the waterproof qualities of ignition systems in general. This offer is to be held open for thirty days. The judge must be the editor of some magazine to be chosen by the competitors.

George Westinghouse, of Pittsburgh, has invented an air spring for automobiles which he says will decrease the expense of running rubber-tired vehicles about 60 per cent., and which he hopes ultimately will cut down prices materially by doing away with rubber tires. The device is based upon the idea of the plunger elevator. One of the springs is placed under each of the corners of the body, and they are said to take up shocks with much greater facility than rubber tires. The idea of the inventor is to use steel tires with the air springs.

Among the Various Agencies

John M. Weaver, of the Pittsburgh Speedway Motor Company, has secured the Pittsburgh agency for the "Henry 35," which is manufactured by the Henry Motor Car Company, of Muskegon, Mich.

The Greenville Motor Car Company, of Greenville, S. C., has been added to the list of Selden agents in the South. Alvan H. Doty, Jr., of Staten Island, is another new Selden agent.

The Brush Runabout has invaded the Seattle territory, the agency just having been established by Samuel Polacheck, who has been associated with the Brush Company at the Detroit plant. The location is at 305 East Pike street.

Michael Abol, of Columbus, has taken the Central Ohio agency for the Baker Electric. He has joined with H. E. Evans in the agency and a location will be found for the salesroom in the business section of the city.

The Babcock 30, which sells for $2,250, is another car to enter the Baltimore field. It is handled by the company's local office at 107, 109 and 111 West Fayette street, H. Davis Coulson being the manager of that establishment.

James A. Hill, of Lafayette, Ind., has taken the agency for Halladay cars in Lafayette and vicinity, and will start the erection of one of the largest garages in northern Indiana. He will look after the agents in North Central Indiana for the factory.

Jesse C. Stewart, Pittsburgh agent for George C. Christian Milling Company, of Indianapolis, has bought one of the finest sites in the city on Centre avenue near Morewood avenue, and will build an eight-story garage at once.

A new company has been formed at Monessen, Pa., to distribute the Lyon motor car throughout five counties of western Pennsylvania; namely, Westmoreland, Washington, Fayette, Allegheny and Beaver. The officers of the company are: President, George H. Stevens; vice-president, J. J. Cushing; treasurer, William Herron; secretary, J. B. Culler.

H. E. Wilcox Motor Car Company, of Minneapolis, has appointed the following agents: Russell Motor Car Company, at Duluth; Pioneer Auto Company, of San Francisco; John Deere Plow Company, Omaha; McGee-Huckell Motor Car Company, of Kansas City, Mo.; Wilcox Motor Car Company, Chicago. Trucks are being delivered all over the Northwest.

New Iowa Agencies are: Iowa Auto & Tire Company, Davenport, Ia.—Thomas, Cadillac, Pierce-Arrow, Babcock Electric, H. W. Meier Company, Davenport, Ia.: Reo, Jackson. Bernhard & Turner, Des Moines, Ia.—Columbus Electric. Musgrave Auto Company, Des Moines, Ia.—Black Crow. Harding & Blenkinson, Sioux City, Ia.—Everett "30." Capital City Automobile Company, Des Moines, Ia.—Columbia. Buick Auto Company, Des Moines, Ia.—Packard. Cruzan, Des Moines, Ia.—Interstate.

Coker F. Clarkson, Secretary of the Society of Automobile Engineers

Richmond, Va.—The City Council recently passed an ordinance governing the speed limit for autos and vehicles, which raises the limit from eight to fifteen miles per hour.

The Belle Terre Club, of Port Jefferson, L. I., will open its clubhouse for the season on June 11. Elaborate arrangements, including a luncheon and other entertainment, are being made.

G. W. Bennett, Eastern manager of the White Company, has resigned to take the position of general sales and advertising manager of the Willys-Overland Company, of Toledo. He assumes his new duties June 1.

Information received in Lansing is to the effect that the General Motors Company will take over the plant of the Seager Engine Works. The report has not been officially confirmed, but it is said to be on good authority. The supposed merger, it is said, is to take place about June 1 of this year.

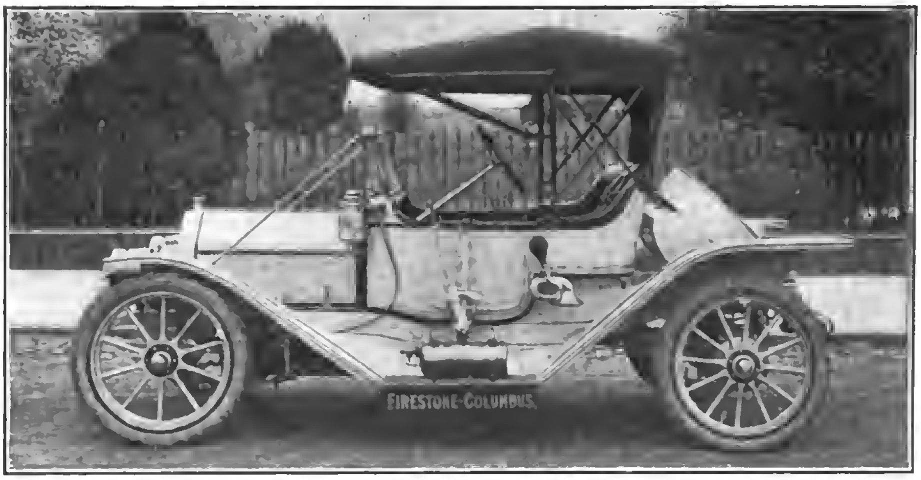
The United States Circuit Court at Chicago has handed down a decision through Judge Sanborn which is of marked importance to the automobile public. Parsons patent No. 723,299 covering chain grips for automobiles is sustained.

Demand for cars has brought several new machines into Omaha during the past few days. The Sweet-Edwards has brought out the R. A. C.; F. C. Henry has introduced the Henry; the Standard Auto Company is showing the Westcott; the Omaha Auto Company has the Demot, and C. F. Louck the Abbott-Detroit.

The Michelin Tire Company, 1344 Michigan avenue, has removed to 1449 Michigan avenue, Chicago, Ill., taking over the building which was formerly occupied by the Tennant Motor Car Company of that city.

Spokane automobile dealers are planning a speed contest early in June, to be run from Spokane to Lewiston, Idaho, and return. The roads between these points will soon be in excellent condition.

W. L. Velie, President Velie Motor Co.



Firestone-Columbus roadster type with top ready for the road.

Frank H. Cross, manufacturer's agent, has recently associated himself with several others and is now doing business under the name of the Frank H. Cross Distributing Company at 1777-1779 Broadway, New York City. The company is the sole distributor of several accessory and parts manufacturers, including complete chassis, and only sells to automobile manufacturers and accessory jobbers.

Doings in the Garage World

F. C. Caldwell, formerly connected with the Missouri Valley Auto Co., expects to open a garage in Kansas City.

The Gordon Motor Car Company will enter its new garage in Richmond, Va., within a few days.

William W. Pope & Sons, Netcong, N. J., have completed a garage at that place. They have 1,500 square feet of floor space and an adequate plant for doing all kinds of work.

The Fourth Street Auto Garage Company, of Barberton, Ohio, was opened recently by G. E. Gardner. The concern acts as agent for the De Tamble and Halladay lines in three counties.

Work on the S. H. Lewis garage at Binghamton, N. Y., is progressing rapidly. The structural work is of steel and concrete, and it is intended to have the building completed in the course of a month.

The Fawkes Auto Company, of Minneapolis, is beginning the erection of the new garage and sales building at Erie street and Hennepin avenue. It is planned to complete the structure January 1.

The Metropolitan Motor Car Company at Wenatchee, Wash., is erecting a garage to cost $36,000. The building is of reinforced concrete, 120 by 160 feet, and two stories in height. Captain C. C. Griggs is manager of the Wenatchee branch.

William H. Lee is building a garage in Thirtieth street, Indianapolis, and expects to take on one or more lines of cars. At present Mr. Lee is chief clerk of the city building inspection department.

Fred A. Wing, of the Broadway Automobile Company, Seattle, announces that work will commence on an exclusive electric garage for the Detroit electrics, the building to be 50 by 128 feet on Broadway, between Olive and Howell streets.

August Zander will build a garage in Stanton, Neb. The building will be of cement construction and will be 25 x 80 feet with all modern appliances. A number of Stanton people who have held back because there was no garage in town will now purchase autos.

Carl Mielcke and Fred Kunz, of Pittsburg, has purchased, through the Baker-Herbig-Royer Company, the garage formerly operated by Siegrist & Sons, in Coshocton, O. The new company, in addition to operating the garage and repair shop, will take the following agencies: White (gasoline), Maxwell, Columbia, Speedwell, E-M-F and Rauch-Lang.

Brief Personal Mention

E. T. Elder and C. W. Struve have bought the interests in the Parsons, Kas., Motor Company formerly controlled by Kimball & Delay.

W. H. Argabrite has been appointed assistant secretary of the Louisville Automobile Club, to succeed E. J. Bohannon, who resigned last month.

John Ryan, formerly of the Factory Sales Corporation, selling Schebler carbureters, has been engaged by A. R. Mosler & Company.

J. L. Barker, of Racine, Wis., inventor of a puncture-proof tire, is now at work on a self-starting device for motor cars. The experiments are being made on a Mitchell.

Prominent Automobile Accessories

SINGLE SECTIONAL MOTOR TRUCK TIRE

An interesting thing in the rubber tire world at the present time is a sectional tire for trucks which has but a single row of rubber sections. Heretofore most tires of this kind have been made in the twin form, the sections being staggered to make, as nearly as possible, a continuous tread. This new single sectional tire is a "Kelly-Springfield" made by the Consolidated Rubber Tire Company of New York, and Akron, Ohio, and has the good construction and high grade composition that characterize all tires bearing that name.

The clever feature of this new tire is the peculiar shape of the segments, which, as you will see from the illustration, are narrower at the rim than at the outside edge, so that under the weight of a load the ends of the sections meet at the outside edges.

The jar and vibration common to most sectional tires of the staggered variety is entirely absent where this single sectional tire is used, and actual experience has proved that engines do better work and last much longer where this resilient, smooth running tire is used.

AUTO DRAFT IS A HANDY DEVICE

The illustration here given of the "Auto Draft" made by the Auto Draft Company, Lake City, Minn., is shown with its parts complete, ready to use on an automobile. In practice, the drum part is bolted to the hub of the rear wheel, one on each side, if it is desired, although it may not be necessary, and with the "spike" which, in practice, is driven into the ground, an anchorage is afforded by means of which the steel cable is held. When a car gets stuck in the mud all that is necessary is to attach the cable to the spike, take a turn around the drum, start the motor, and "out she comes."

HIGH DUTY HYATT ROLLER BEARINGS

The fundamental feature of all Hyatt bearings is its distinguishing flexible roller. By "flexibility" is meant its adaptability to irregular conditions that are always present to a more or less extent in the practical manufacture and operation of any mechanical device. This is made possible by the character of the Hyatt roller, which is not solid, but made from rectangular steel wound in a suitable manner and in such a way as to form a spiral.

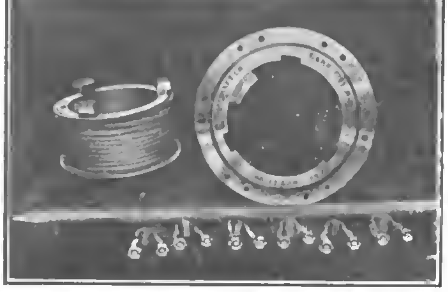


Fig. 1—Auto Draft and Parts, which is Used to Pull an Automobile out of the Mud

Such rollers are not flexible in the sense that they cause the shaft or axle to spring or vibrate, or the gears to lose their alignment. They simply serve to cushion or relieve the shocks to which all parts of the car are subjected. In this manner they greatly reduce the liability to breakage and increase the life of the bearing and the car as well. Those who have experimented with such matters realize what an infinitesimal amount of give, or elasticity, will effect the result.

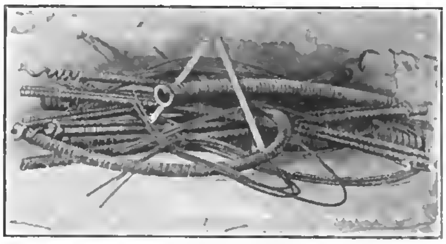

Fig. 2—Early Process in the Manufacture of Hyatt "High Duty" Roller Bearings

The rollers being hollow, they carry an unusually large amount of lubrication. The spirals in the rollers alternate from left to right, thus insuring perfect lubrication at all times. If there is any of the lubricant in any part of the bearing it will be evenly distributed.

There are two separate and distinct types of the Hyatt Roller Bearings, the commercial type and the High Duty type. The High Duty type involves the substitution of alloy steel properly treated, for the carbon steels in the commercial type rollers. This necessitates properly prepared inner and outer surfaces on which and in which the rollers operate.

This design enables a greatly increased load to be concentrated on the same section, or the same load on a smaller section. It makes this bushing particularly adaptable where the available space for a bushing is limited, and as all designers are now striving to do, make a small compact bearing.

Only selected alloy steels are used and all material is carefully checked by both mechanical and physical tests before it is accepted. The physical tests include the carrying of the material through all the necessary heat treating, in order to insure the maintenance of certain prescribed standards set for this particular type of bushing. The completed rollers are ground to size and inspected to within suitable limits.

THE USE OF THE BRAKES

Use the brakes with judicious care and motor tire mileage and general service will be greatly increased. This advice to automobile owners, says the Diamond Rubber Company, is well worth careful consideration, and, while not as important as ample tire inflation, perhaps is given heed by most drivers. Each application of the brakes causes some strain on the tires as well as in the transmitting parts of the machine. This strain, if constantly recurring, will, of course, result in the more rapid wear of the tires.

"The best drivers use the brakes very little," says Theo. Weigele, of the Diamond Company, "and their tire service is better because of it."

In ordinary road running—save in emergency cases—the engine may be employed to do the work usually required of the brakes. It is surprising how smoothly and efficiently a car can be handled without the use of the brakes after a little practice.

PERFECTION BATTERY CHARGER USES

The illustration here given is of the "Perfection" battery charger, made by the Economy Manufacturing Company, Park Building, Pittsburg, Pa. The charger is used for the purpose of charging ignition batteries as used in automobile work, and it has the virtue of solving what the average autoist calls a rather serious problem. The construction of the charger is along the usual lines, involving permanent magnets and an armature with a commutator, so that the current delivered is of the required voltage for charging work, hence the use of a commutator instead of collector rings. The magnets are of tungsten steel and the armature windings are carefully proportioned for the work.

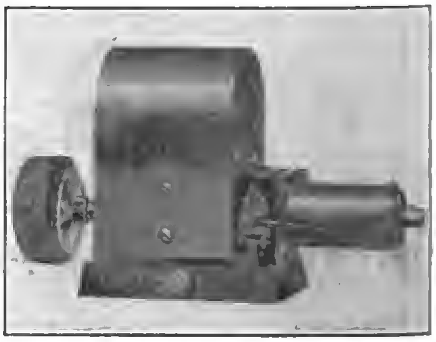

Fig. 3—Perfection Battery Charger which Takes the Place of a Troublesome Process

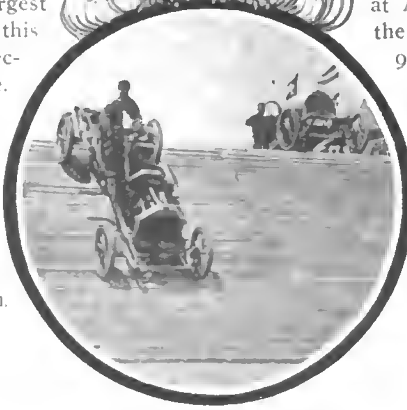
VOL. XXII. NEW YORK—THURSDAY, JUNE 2, 1910—CHICAGO No. 22

THE AUTOMOBILE

Records Fall at Indianapolis—W. & S. Cup to Marmon

On the Straightaway at the Indianapolis Speedway

INDIANAPOLIS, May 31.—The three-day racing carnival on the newly-surfaced motor speedway was brought to a conclusion yesterday afternoon, when probably the largest crowd that ever attended a similar event in this country watched the sport. Fully 60,000 spectators sat out the interesting programme. The feature of the carnival was the 200-mile event for the Wheeler & Schebler trophy for Class E cars, of 600 cubic inches piston displacement or less, and of a minimum weight of 2,300 pounds. Ray Harroun, driving a Marmon Six, was the winner; Lynch, Jackson, second; Aitken, National 40, third; A. Chevrolet, Buick 16B, fourth.



Making the Hurdle

Records went by the board all along the line. Kincaid, National, took 24.88 seconds off the 100-mile record of 1:24:08, made by Chevrolet at Atlanta. Aitken's (National) 8:08:36, made in the 10-mile event for 301-450 cubic-inch cars, was 9.16 seconds better than Chevrolet's best previous. Kincaid (National) lowered the 301-450 5-mile figures by 40 seconds, and Chevrolet, himself, took a hand in the general onslaught, the big fellow sending his Buick over the line 49.10 seconds better than the record in the Class B 160-230 10-mile race on the last day. National, Knox and Marmon each won two championships.

Bridgeport Hill Climb

Fig. 1—Rankin in Chalmers having a say
Fig. 2—National doing its expected work
Fig. 3—Mullins in Buick free-for-all
Fig. 4—Correja car driven by Taylor

Bridgeport, Conn., May 30—While hundreds of people lined the winding ascent of Snake Hill, Fairfield, Conn., the hill climb of the Bridgeport Automobile Dealer's Association was held this morning. Notwithstanding the injunction brought against the association by Frederick Sturges, New York millionaire, the climb was successful in every sense of the word. Although the steep hill was well soaked with the early morning rain the cars made good time. "Billy" Knipper, piloting a Chalmers, made the best time of the day, covering the seven-tenths mile course in one minute and eight seconds. Sixty members of the Coast Artillery guarded the course and no accidents marred the contest, although many narrow escapes occurred at "Deadman's Curve," which was the most perilous of the course. Dean Rankin in a Chalmers took the curves very fast, it was said, but lost time on the steep grades. Thomas H. MacDonald, of the Automobile Club of Bridgeport, acted as referee, while C. H. Gillette, president of the Automobile Club of Hartford, was the A. A. A. representative. Members of the Automobile Club, including F. T. Staples, F. W. Blolande, F. A. Rantz and R. M. Sperry, acted as the other officials.

The climb started promptly at nine o'clock with Events Nos. 1, 6 and 7 scratched on account of not filling, leaving seven to be contested. The first car over the finish line in the $851-$1,250 event was a Warren-Detroit, driven by J. H. Brooks which covered the course in 1:59.

A Correja, driven by J. Taylor, won the $1,251 to $1,600 event in 1:41; H. P. Hardesty's Pullman finishing second in 1:48 1-5.

The event for $1,601 to $2,000 stock cars was easily won by a Pullman driven by J. J. Schenck, in 1:34 4-5; the Stoddard-Dayton driven by H. B. Griffin, finishing second in 2:06.

Dean Rankin in a Chalmers had no trouble in winning the $2,001 to $3,000 stock car event in 1:18. He drove one of the finest races of the day, and took the curves beautifully without slowing down.

The free-for-all furnished the real excitement of the day, and the crowds went frantic when "Billy" Knipper piloted a Chalmers over the course in 1:08 3-4, making a new record for the hill. Rankin in another Chalmers won second honors in the event. His time was 1:15.

New Haven men won both motorcycle events, G. A. Wildman, Indian, that for single-cylinder machines in 1:26 1-5, and P. H. Cox the second in 1:13 1-5, also on an Indian. The summary:

$851 TO $1,250 STOCK CARS

No. Car	Driver	Time
1—Warren-Detroit	J. H. Brooks	1:59

$1,251 TO $1,600 STOCK CARS

1—Correja	J. Taylor	1:41
2—Pullman	H. P. Hardesty	[illegible]48 1-5

$1,601 TO $2,000 STOCK CARS

1—Pullman	J. J. Schenck	1:[illegible]
2—Stoddard-Dayton	H. B. Griffin	2:[illegible]

$2,001 to $3,000 STOCK CARS

1—Chalmers	Dean Rankin	1:[illegible]

FREE-FOR-ALL

1—Chalmers	"Billy" Knipper	[illegible] 3-4
2—Chalmers	Dean Rankin	[illegible]
3—Correja	J. Taylor	[illegible] 4-5
4—Buick	J. McMullin	[illegible]

Harbach Asks Recognition

Secretary Harry C. Harbach, the wide-awake official [illegible] Quaker City Motor Club, has entered a protest against [illegible] of the "secret time schedule" devised by him for the road [illegible] runs of the Quaker City Motor Club by other clubs a[illegible]ganizations unless due credit is given his club. Mr. H[illegible] suggests that promoters planning runs under a secret [illegible] schedule insert a line in the captions of their literature a[illegible]ing credit.

Sheridan Hill Climb

BUFFALO, N. Y., May 29—With the low and winning score, a small-powered Ford touring car finished first in the hill-climbing contest held on Sheridan Hill, near Forestville, under the auspices of the Dunkirk (N. Y.) *Observer*, yesterday afternoon. A Marion Roadster of 35 horsepower was second, while a Buick surrey, 18 horsepower, was third. Behind these placed cars ten others finished, many of them possessing more engine power than the winners.

Such a result was made possible by an original and ingenious plan of handicapping, which was devised by E. D. H. Caldwell, chief engineer of the Chautauqua Motor Company, and approved by Dr. A. Wilson Dods, H. J. Thompson and other officials of the contest.

The plan in brief was as follows:

The cylinder volume of each contesting car was multiplied by the number of seconds required to make the run up the hill in a first contest; then, from that was subtracted the total points gained by the same car in a second contest, the hill being divided into sections, so that a car was awarded 500 points for covering the first 500 feet, on high gear, three points for each foot in the second section, five points for each foot in the third section, eight points for each foot in tne fourth, ten for each foot in the fifth and 25 points for each of the remaining ten feet at the top of the hill. The car which, at the end of the two contests, bv subtracting the points gained in the second contest from those awarded in the first, had the smallest score was the winner and was awarded the cup for first prize.

The contest was unlike the usual hill climb, by reason of the fact that the smaller cars, instead of being placed at a disadvantage, had if anything, a little the better of the argument. Some slight alterations in the plan might make it a fair basis upon which similar contests may be held in future.

The contest was up the steep Sheridan Hill, just outside of Forestville, N. Y., a hill which is conceded by motorists to be one of the most difficult to ascend in this part of the country. The hill is about half a mile long and at different points the angle of its rise is said to be greater than 45 degrees. The contest was limited to gasoline motor cars that were either sold by agents or owned in northern Chautauqua County, N. Y., all of the cars being required to be equipped ready for road use with the exception that the tops and the glass fronts, usually carried, were allowed to be removed.

Under the original plan the contest was to have been conducted last Thursday, but owing to the treacherous condition of the hill, because of the heavy rains during the early part of the week, the event had been postponed until yesterday. There had been 22 original entrants for the contest, but of the number only thirteen actually competed, some cars being withdrawn previous to the day and others because of minor derangements which would have delayed the event had time been taken to make the necessary small repairs.

An added feature of the afternoon's sport was an exhibition of climbing the hill by James C. Barclay, of Buffalo, in his Model K, 70-horsepower, Thomas racer. This feature had no bearing on the actual contest, but was given to demonstrate the ability of Mr. Barclay's car, which was recently built for him by the E. R. Thomas Motor Car Company. The racer went up the hill without any difficulty in 55 seconds, which was more than ten seconds better than the fastest performance of any car in the actual contest.

The officials of the contest were: Judges, H. J. Thompson, Dr. A. Wilson Dods, Walter Record, F. R. Wilson, P. F. Valentine, E. D. H. Caldwell, Dr. M. S. Coxe; Starter, G. B. Williams, editor of the Dunkirk *Observer;* Timers, Dr. A. Wilson Dods and E. D. H. Caldwell; Clerk of Course, G. E. Frey. The tabulated result of the contest follows:

Amateurs' Hill Climb Held in Westchester

A—J. D. Hooker third in fourth event with Stearns car. B—Simplex 90 driven by G. B. Lambert, who took away the record. C—Speedwell driven by H. A. Weatherbee. D—National driven by L. M. Rutherford, which made excellent time and performed excitingly.

WITHOUT a single hitch in the program and favored by every natural condition of advantage, the first scheduled event of the Amateur Automobile Contest Association, a hill climb staged on Anderson's Hill, near Harrison, New York, was held Saturday afternoon.

There were four fixed events and a motorcycle contest for which policemen in that branch of the service were eligible to enter. Aside from the four officers who took part in that event, the participants in the racing were all wealthy young men who drove their own cars.

The scene of the contest is a beautiful spot about two and a half miles from White Plains. The course was laid out over a splendid roadway, exactly a measured mile. The start was on a straight, level bit of ground about 300 yards long where it swerved to the right and climbed a long hill whose stiffest grade was 11.25 per cent. The average grade of the whole mile was 5.81 per cent. At the top of the hill there was another swerve to the right and, passing a series of reviewing stands, the contestants dropped down a short, sharp grade to the finishing line.

The course led past the Oliver Harriman and Whitelaw Reid estates, and in the crowds of spectators were many persons of national importance and prominence.

The motorcycle race was decided first, and of the thirteen original entries, four accepted the issue. The winner turned up in Patrolman Ruggiero, of the Scarsdale force, who drove an Indian machine across the line in 1.07 1-5. Officer Ball, of Rye, came second with another Indian in 1.16 2-5. In addition to the medal and purse offered by the association for the winner of this race, George W. Quintard 3d, presented a beautiful medal.

The other races were strictly for amateurs and all of them proved to be stirring contests.

The fastest time made during the afternoon was by G. B. Lambert in his Simplex 90, who won the free-for-all event in 1.03 flat. Mr. Lambert's performance won him two valuable cups, the regular first prize offered for the winner of the event and a special cup, hung up by President Northrup Fowler of the contest association for the fastest time made during the meeting.

George W. Quintard 3d, in a Simplex 50, captured the Vice-President's cup for the high average made in two or more trials. This trophy was given by Richard M. Jesup. In addition to that prize, Mr. Quintard was second in event No. 3 for Class C, Subdivision 5, cars, with piston displacement of from 451 to 600 cubic inches.

The Class Cup, presented by C. A. Fowler, Jr., for the fastest time made in Classes 1, 2, 3, 4 and 5, was taken by S. E. Wishart in a Mercedes, who won the preceding race in 1.05 flat.

The "Git a Horse" cup, presented by J. G. Wilson for the slowest time made by any car in the racing, was won by Mr. Wilson himself, in his Lancia car in 1.44 1-5 in the free-for-all.

The officials of the meeting were as follows:

Referee, W. A. Whiting; Judges, William Bruce Brown, Robert L. Chamberlain, Claude D. Sterling, Charles D. Lanier, Bradford Ellsworth, Edwin N. Chapman, Robert McC. Butt, William W. Heaton, Louis P. Fish; Starter, John D. Chapman; Clerk of the Course, Edwin Moore; Scorers, Reginald M. Johnson and Chauncey B. Griffen; Timers, The New York Timers' Club; Technical Committee, A. L. McMurtry, Chairman.

The officers of the association are as follows: President, Northrup Fowler; Vice-presidents, Richard M. Jesup, Henry H. Law and John M. Rutherford; Secretary and Treasurer, J. Gilbert Wilson; Board of Directors, C. M. Chauncey, C. A. Fowler, Jr., Northrup Fowler, R. M. Jesup, H. H. Law, J. M. Rutherford, J. Thompson, J. D. Tooker and J. G. Wilson.

The event was one of the most interesting of the season thus far, and that it will be repeated is to be hoped at least. The participants all agree that the good of the industry was well cared for.

(Continued on page 1026.)

Central New York Run Was a Pleasant Jaunt

A—Cars Checking in at Binghamton. B—Whiling Away Time at the Ithaca Game. C—Messrs. Ritchie and DeWitt in car; Commissioner Lyon standing. D—Official Thomas Car; Commissioner Lyon in front and William Pierrepont White at the rear.

UTICA, N. Y., June 1—The third day of the Central New York Relay Run was made in a hard rain, which lasted most of the day. It had been intended to stop over night at Richland Springs, but on reaching Five-Mile Point Inn the officials decided to change the itinerary and the night was spent at the Inn, after a banquet and dance. At Oneonta a luncheon was provided by the local club.

The third day brought out the first accident of the run. In coming around the turn in Oneonta from the country road onto the paved main street, an Oakland 24, driven by T. F. Willis, skidded forward into the curb on the opposite side of the street. The right front wheel was bent clear around and under the car till its diameter was parallel with the street. In this position the car swung clear around and across to the opposite curbing. Apart from the bent axle there was no damage done, Willis and his companion holding their seats and alighting unhurt. The axle was taken off, bent straight and the car continued the run in good shape.

The run here this morning found the roads in splendid shape. Even the hard rains have not spoiled the pleasure of the tour. This afternoon Rome and Oneida will be visited, and the run will finish in Syracuse this evening, where a Dutch lunch will be served. Fourteen cars started from Syracuse Saturday morning over roads which, as a result of almost continuous rains the preceding week, were in anything but first-class shape. Additions made to the list of entrants at Auburn and Cortland brought the number up to an even score. Unfortunately an escort of twenty cars sent out to meet the travelers and show the way through Cortland failed to make connections through some misunderstanding of road orders. At Ithaca the local motorists turned out in force and escorted the travelers to the Dutch Inn, where a tasty luncheon was set out, following which the entire party took in the Cornell-Michigan baseball game, the cars being parked along the left field foul line. After the game, still under the escort of the Ithacans, the journey was continued to Watkins Glen, where the night was spent at Glen Springs Hotel.

Sunday morning, following a thoroughly enjoyable trip through Watkins Glen, the journey was resumed to Elmira, an escort of seven cars meeting the tourists about ten miles out, and leading the way to the Hotel Langwell, where dinner was served. In the afternoon the route was taken for Binghamton. At Owego fully a hundred cars were found drawn up along the road waiting to escort the tourists to the night stop. Binghamton fairly outdid itself in welcoming and entertaining the visitors. At dinner J. E. P. Clark acted as toastmaster, and among those who responded to toasts were William Pierrepont White, the "Father of Good Roads" in New York State; Frank T. Lyon, of the State Highway Commission, and J. Arthur Ritchie. Letters were read from S. Percy Hooker, Commissioner of Highways of New York State; Lewis E. Speare, president of the A. A. A., and Frank G. Webb, president of the State Association.

As a demonstration of the perfection already attained in good roads works in Central New York the run is an undoubted success. Barring the first day, when the roads were heavy in many places as a result of the continuous rains, the route selected has been over a literal boulevard—beautiful macadam and hard-rolled earth roads throughout. The promoters considered also the scenery in laying out their itinerary, and the route taken has included many of the beauty spots in the central section of the Empire State. Add to this the stimulating effect upon automobilists generally in the cause of good roads and fair laws, and it may be gathered that this unique outing has exceeded the most sanguine expectations of its promoters.

Fully 200 cars participated in the run during the first three days, dropping in and out at will, and this fact alone seems to demonstrate that cross-country tours, properly managed and conducted under rules, eliminate uncertainties.

Twenty Cars in Washington Post Run

Staunton, Va., May 27—At the conclusion of the first day's run of the Washington *Post's* touring test run from Washington to Richmond and return, it was found that 10 of the 20 cars participating had perfect road and mechanical scores. Although the first 55 miles of the route furnished about as rough and rocky going as could be found anywhere, there is no finer route in this country than that found in the Shenandoah Valley, excellent roads and beautiful scenery combining to make it a favorite touring ground.

The contest is being run under Grade 3, rules of the American Automobile Association, which provide for road and mechanical penalties, but eliminate the outdoor tests at the conclusion of the run. The following are the cars that started, with the names of the drivers:

Fig. 1—Contestants having their photograph taken in front of the Washington Post building

Division 1A—Hupmobile, I. C. Hamilton, driver; Maxwell, A. D. Reh; Paige-Detroit, E. Selby.
Division 2A—Ford, C. E. Miller; Buick, Stanley Mortimer; Ford, E. J. Drake.
Division 3A—Regal, Frank Hosmer; Overland, Clayton Graff; Moline, E. H. Wine; Maxwell, Harry Walls.
Division 4A—Washington, Frank Carter; Washington, W. D. Arrison; Marion, Herbert M. Hall; Buick, "Ted" Johnson.
Division 5A—Oldsmobile, Taylor Pollock; Mora, John J. Fister; Columbia, Bert Robertson; Elmore, Frank Hardart, Jr.
Division 6A—Amplex, Robert Reed.
Division H—Buick truck, Ward Angle.

Most of the small towns situated on the valley pike have strict laws limiting the speed of motor cars passing through them to 6 miles an hour. In every instance but one this law was suspended for the day. The one exception was Mount Crawford. Word had been sent ahead that this hamlet had a speed trap in operation and that preparations had been made for a great haul when the tourists passed through. The timely warning was heeded, and when the village was reached each car passed through at a snail's pace.

Fig. 2—Harry Duckstein, Automobile Editor of the "Post" and Maxwell car

The Regal was the first car to sustain an accident. About 30 miles out of Washington a nut was sheared off the differential, necessitating the boring out of a bolt. This was an all-day job, and when it was finally completed it was nearly dark. The driver made up his mind to reach Staunton and drove all night to do it. The car sustained a penalty of 760 points for being late into Staunton, but its mechanical score has not been determined.

The Elmore entered by Frank Hardart, winner of the Munsey sweepstakes trophy last fall, and driven by his son, had ignition troubles and withdrew from the contest. The car will continue in the tour, however, as a non-contestant.

The Hupmobile has a perfect road score, but lost a point for stalling the motor, 3 points for replenishing the water supply and 6 points for work on the gasoline pipe. For stalling the motor 1 point was marked against the Marion. The Mora lost 3 points for an adjustment of the motor. One of the Ford entries lost a point for tightening one of the lamps and 2 points for stalling the motor. Five points for an adjustment to the carbureter and 6 points for motor stops was the penalty laid against the Paige-Detroit. One of the Buick entries lost a point for work on the hood, while a Buick truck lost 38 points, 31 of which were for being late in the noon control, 3 points for replenishing the fuel and 4 points for work on the car. The Amplex has a perfect mechanical score, but lost a point for being late leaving the noon control.

Richmond, Va., May 29—One-half of the touring test run was completed when the contestants checked in here last evening after a strenuous trip from Staunton. The route was through Rock Fish Gap, one of the hardest roads to negotiate to be found in seven States. A new road is being cut through the gap and is only half completed, but this was the route selected and the tourists had to take it. When completed this will be an excellent road and the private citizens who have contributed money to build it are to be congratulated on their public-spiritedness.

Fig. 3—Just started, the run is taking departure from in front of the Washington "Post"

Washington, D. C., May 31—The finish of the *Post* touring test run found the Overland eliminated from the perfect score class by reason of loose spring clips, a penalty of 25 points being inflicted. The Marion lost a point for a motor stop. The Buick truck lost more points yesterday, a total of 111 being marked against it. For stalling the motor another point was placed against Paige-Detroit. The technical committee last night gave the Regal a total of 1,145 points for its first day's troubles, and also placed Maxwell runabout back in clean score class by lopping off the 2 points penalty imposed on the second day for work on the oil regulator. The 1 point marked against the Buick the first day for work on top of the hood was also lifted. The run was a great success.

Automatic Stability in Aeroplanes

ADAPTED FROM THE GERMAN OF R. CONRAD BY MARIUS G. KRARUP.

MEANS for imparting automatic stability to aeroplane machines are considered in a series of articles in *Der Motorwagen* by the editor of this publication, the civil engineer Robert Conrad. He shows by a large number of photographic reproductions the many different ways in which aeroplane machines have lost their balance in the air and have been precipitated to earth, now in one position and now in another. An extract of the reasoning which he offers on the subject of the available mechanical expedients for avoiding similar downfalls in the future is presented in the following:

By automatic stability is sometimes understood the stability resulting from the relative positions given to the various immobile surfaces and weights. The automatic stabilizers here to be considered are something different, viz., apparatus which, by operating control surfaces, automatically rights the aeroplane when it threatens to upset, either laterally or longitudinally. The following stabilizers may be mentioned: pendulums, klinographs, feeler-areas and gyroscopes, the latter acting either on control surfaces or direct on the main planes.

The pendulum principle is most logical when the weight of passengers and motor is used as the pendulum weight. A heavy weight is necessary in order to have it operate front or rear tilters, ailerons or a main-plane warping-device. Light pendulums could be used only as a means for releasing a more powerful apparatus and making its forces operate in the right direction. A diagram indicating how the pendulum might be used for adjusting ailerons is shown in Fig. 1A.

At a turning movement of the machine the pendulum acts, of course, unfavorably, and it has been tried to lock the pendulum during a turn by pedals arranged for this purpose. A drawback to the pendulum plan is that sudden gusts which affect the whole machine and merely push it sideways in the atmosphere, parallel with itself, also make the pendulum swing. This would be a source of danger. To use the pendulum for correcting the longitudinal balance seems very difficult, as any ordinary pendulum reacts for accelerations and retardations the same as for changes of poise. Every retarding wind would cause the pendulum to swing forward, producing the same control action as if the front of the machine had dipped, consequently retarding the machine still more and producing an exaggerated rising effect, since the contrary wind in itself has a tendency to make the machine rise. On the other hand, under the influence of a gust of wind from behind, the pendulum would have the effect of helping to produce a headlong fall. Fig. 1B illustrates these shortcomings of pendulum control, the upper diagram showing the action in case of a sudden increase of headwind resistance, and the lower one the same pendulum action, but due to a forward dip of the machine. In both cases the pendulum is assumed to operate the tilt rudder.

In other words, the free pendulum acting on control apparatus, is not in itself a good automatic balancer. A mechanism is conceivable, however, by which the pendulum would no longer act the same way for changes of inclination as for changes in speed. The pendulum could be suspended free to swing in a circle and connected with a horizontal pendulum. In that case, the angle of the pendulum with the vertical would not be changed, or very little changed, by accelerations of the machine.

But from all points of view the pendulum leads to complications, unless it is merely employed to indicate in what manner the control apparatus shall be operated.

To indicate the many possibilities which exist theoretically for automatic balancing apparatus, the klinograph or angle indicator may be mentioned. It would be possible to arrange a disk on a horizontal axle and protected against the wind with so little frictional resistance that it would remain stationary, whatever the change in the position in the air of the whole machine, and it would therefore show directly any deviation in angle from the previous direction of the latter. The problem of translating into control movements the relative changes between the axle of the disk and its frame by means of electrical, frictionless contacts, may be a difficult, but future solution.

Still farther in the future lies the employment of what might be called sense organs for the flying machine, meaning thereby light and mobile surfaces, so arranged that if one of a pair is affected by the wind its movement—or the differential movement of the two feeler-planes—is communicated to a control apparatus, not so as to operate this control apparatus, but so as to indicate at a very early moment of the disturbance in what manner the control apparatus should be operated. By means of a compressed-air device, steam or other intermediating element of releasable power, a very slight difference in the pressures communicated from two feeler-areas could readily be made to actuate a counter movement of the real control areas almost before the machine as a whole had felt the effect of the gust of wind or other disturbing factor against which the feeler-organs reacted. The flexible uprights in the Wright tilt-rudder may indicate a conception of this nature on the part of the Wrights, though probably only in a subconscious state.

The gyroscope is probably the best but also the most expensive stabilizing device for the present stage of the development. As heavy and complicated as in the Scherl-Brennan monorail car it would not be applicable to flying machines, but such a heavy

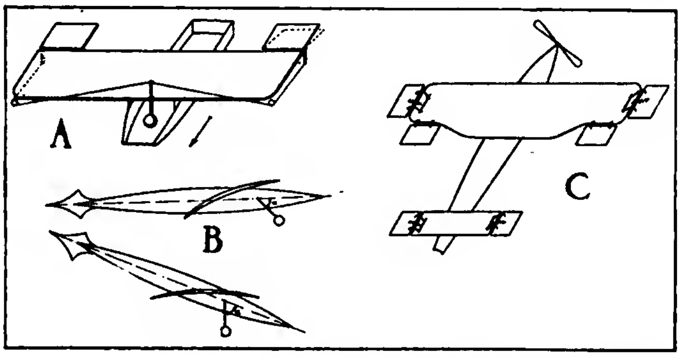

Fig. 1—A, automatic control of ailerons by pendulum. B, pendulum reacts for retardation, upper diagram the same as for pitching, lower diagram. C, feeler-areas, spring-attached, easily deflected, a possibility of the future.

and complicated apparatus is also not required for the work to be done.

The rotating Gnome motor is considered such a gyroscope, and Farman claims that he can detect the righting effect of this motor very plainly, but the true merit of this type of motor is probably much more the flywheel action of the cylinders, by which stalling of the motor from poor carburetion or faulty ignition is obviated, the momentum giving the motor a chance to recover. In the Gnome motor the weights are also not peripherally located, nor is the speed very high. It would be possible to obtain a 16 times higher gyroscopic effect with a much smaller weight rotated at a four times higher speed, if it were desirable to employ gyroscopic action of such force. But it is preferable to get along with much smaller weights and forces. It might be considered to place the axle of the gyroscope vertically, so as to avoid resistance against side-steering, but the vertical position of the shaft would oppose the natural canting of the machine in the curve, and an oblique ascent or descent would also be hindered.

(To be continued.)

How About Starting on the Spark?

AUTOISTS, when they are wont to represent, in the most convincing way, the excellence of their respective makes of automobiles, use as one argument the fact, as they say, "it will start on the spark every time." The real question is, will it? If not, what is the percentage of the total number of times that the average automobile will start on the spark? If it will start in this way, with great reliability, then, let us take up the question of the desirability of doing so. Salesmen, considering the class who rely upon "selling points" for their results, will be glad to have every prospective purchaser believe that starting on the spark is only possible every time with the particular automobile they are interested in, but will it?

Just how much of a twist the crankshaft will receive when the start is made by the spark from a dead standstill, is a matter that can not be disposed of in the abstract. It depends upon the weight of the flywheel, radius of the rim of the same, and such considerations. Fortunately, single cylinder motors, with their large flywheels, cannot be made to start from the spark. It is highly improbable that the crankshaft of the average single cylinder motor would survive the shock for long.

Some Expressions of Opinions From Autoists

The following are expressions of opinion from autoists, who, in protest of an answer which was made to a letter of inquiry in relation to this question of starting on the spark, offer the evidence of experience to show that starting on the spark is not only perfectly feasible, but a very regular proceeding:

(A) "In regard to your letter number 2201 entitled 'Starting on the Spark,' your reply says that you doubt if the experiment spoken of, in which the spark plugs and other parts were removed from the cylinder, leaving them open to the atmosphere, and that then after replacement the engine was started on the remaining mixture, on the spark ever happened, or could be made to happen.

"For your information I would say that, after running my engine one day last summer and having a skip, I removed my four magneto plugs. I cleaned these plugs, adjusted the points, put the plugs back, threw on the spark and my engine started. My brother went me one better. He has the same kind of a car and removed both his battery and magneto plugs, cleaned them, put them back, threw on his spark and his engine started.

"Both of us will be willing to swear to the above statements before a Notary Public.

"Your answer to letter No. 2201 would lead people to believe that it was necessary to have gasoline under compression to get an explosion, but the general public know from items in the daily papers that gasoline often explodes when it is not under compression. I wish you would state these facts in your 'Letters Answered and Discussed' and would appreciate having a personal reply with your views on this subject."—Harold W. Pierce.

(B) "Referring to letter No. 2201 appearing in your issue of March 24, and your answer thereto, I think you are astray when you make the statement you do as to the doubtfulness of the experiment spoken of being successful, as I have proved many times that this can be done, and that compression has very little if anything to do with the possibility of starting on the spark. In a number of instances I have removed completely the spark plugs from my car and after replacing them, started the engine on the spark. My theory is that if the cylinder is filled with an explosive mixture of gas, and the engine runs freely, there will be sufficient force to start same."—M. J. O.

(C) "In your issue of March 24, on page 599, we notice that in your answer to the question asked by the subscriber signing himself 'Amateur,' in the last paragraph thereof, you say it is doubtful if an automobile was ever made to start on the spark when the spark plugs had been removed, since the engine was run. This seems to be a common-sense view of the matter theoretically, but practically, it is dead wrong. The writer has done this many times, not only accidentally, but has done it intentionally with five or six people watching. In fact, if the engine and the mixture are carefully adjusted, the car will start on the spark at least nine out of ten times immediately after stopping. It will start about one-half the time if all four plugs are removed and then put back."—Waterman Brothers Company, Incorporated.

(D) "Regarding your answer and information to letter number 2201 in your issue March 24 (starting on the spark) you are entirely incorrect in your answer.

"I know that motors that have a very low compression start best from the switch, in fact, it is not unusual for an old motor to start from the switch the next morning after having been used the evening before say up to six or seven o'clock. The writer also remembers that in 1906 a car was put in a freight car, shipped and when this car was unloaded the motor started from the switch after being in transit for 5 days. Where was compression after such a length of time and after such a jar and jolt that a motor gets in transit?

"I also well remember that in 1906 I overhauled and thoroughly cleaned a 1905 motor, having the cylinders, pistons, and piston rings removed, reground the valves, and really had the crankshaft out of its bearings. Now, after reassembling this motor, setting valves and time of ignition, I injected a little gasoline through the pet cocks into each cylinder, and on throwing on the switch the motor started away beautifully, to my utter astonishment, without ever touching the crank. Where was compression in this instance?

"When I know facts like the above, I cannot let it pass by unnoticed, especially while you are telling your correspondent publicly that his informer was not quoting the truth, or rather, put it in such a way as to make readers believe that advice received had been a story. Trusting you will pardon me for butting in, I remain," Jas. D. Reber.

(E) "Have been a subscriber of THE AUTOMOBILE for some time and take a great deal of interest in 'Questions Answered and Discussed.' In the issue of March 24, 1910, I notice an article on starting on the spark in which 'Amateur' states that a manufacturer told him that he (the manufacturer) had removed his spark plugs from his engine, replaced them, and then started on spark. You express doubt as to the occurrence of this, or even its possibility. I noticed that my engine was missing, this morning, and placed the cause of it to dirty spark plugs, which I knew had not been cleaned for some time. About half an hour ago I took out the plugs and cleaned them one at a time, and replaced them in the engine; turned on the switch, and to my utter surprise, the engine started off on spark as nicely as it always does within two or three hours standing. The car has the same engine and ignition as when bought.

"I would like to hear further from you, through the columns of THE AUTOMOBILE in regard to this. I can prove the above assertion to any one so desiring."—Herbert L. Noll.

Some Facts in Relation to Gasoline Performance

The letters as here reproduced are representative of quite a number which were received in relation to this matter, and, without any exception, they all held to the same conclusion. It is proper that they should be published, and the facts should be brought out. The only remaining question is, are the facts brought out?

It is believed that the answer (number 2201 in "Letters Interesting and Discussed") handled the matter rather too briefly, considering the responses it since brought out, and, while it is the necessity in these columns to be brief, there is nothing to prevent enlarging upon the subject elsewhere in The Automobile whenever the occasion demands, as it seems to in this case.

Gasoline Will Not Burn Except Under Compression

Just to show that there is a considerable chance for mistake and that an autoist can be laboring under a misapprehension, attention is called to the letter marked (A) in this series. This letter, among other entertaining statements, is made to state: "I removed my magneto plugs; I cleaned these plugs, adjusted the points, put the plugs back, threw on the spark, and the engine started." This statement would not be very unusual, were it not for the fact that magnetos are so made that, to realize a spark, it is necessary to rotate the armature to get the spark. In this, is an example, according to the language of the letter, of gasoline which "went off" without a spark. Of course, nothing of the kind happened. Either the car was provided with an auxiliary sparking mechanism, or the signer of the letter owes further explanation to the readers of The Automobile.

Disregarding the imperfections of language; coming down to the strictest interpretation, and to the facts, gasoline will not burn unless it is under compression. If this is so, then it is true that a motor cannot be started on the spark, if there is no compression. This compression does not have to be generated by cranking the motor; it will be induced when gasoline boils. Gasoline will boil at its boiling temperature to which it will be heated up; in the cylinders of a motor, if they are warm enough.

Starting on the spark, so-called, is easy enough, perhaps, after a motor has been run, due to the fact that the gasoline is then subjected to a temperature sufficient to cause the liquid to boil, and, as before stated, as the liquid boils, it generates pressure. It is not even the pressure alone that is at the bottom of the ignition of the mixture; it is the gasoline, in gas form, in the presence of sufficient oxygen that makes it inflammable.

If, when a motor is shut down, there is some gasoline present, the heat of the cylinder walls will transfer to the gasoline, and it will be changed in its state of aggregation from liquid to gas. To bring about this result there must be present the set of conditions as follows:

(A) The temperature of the walls and surroundings must be above the boiling point of the gasoline.

(B) The latent heat of evaporation of the gasoline must be equalled by the heat stored in the walls of the cylinders, counting only the heat that may be taken from the walls, before the temperature (sensible) of the walls falls to the boiling temperature of the gasoline which is to be vaporized.

The very fact that the heat stored in the walls of the cylinders is transferred to the liquid gasoline, and it, in turn, is vaporized, is a guarantee that a pressure will be generated. It is this pressure that is in some measure the equivalent of the compression which is induced by cranking the motor, and it is this compression which makes it possible to start, sometimes, on the spark, without previous cranking.

Pumping Losses Interfere With the Process

What are pumping losses? They are all the losses which have to be coped with when a motor is put into motion. They detract from the force of the power stroke. Were there no pumping losses, the motor, were it to be put into motion, would keep on running forever, or, until it assumes the form of a mechanical wreck. The losses, taking them as they come in general practice, are best indicated in the diagram as shown in Fig. 1, which chart was built for the purpose of determining the magnitude of the respective divisions of losses in a motor.

If the pumping losses are very great in proportion, it is then that the motor would start on the spark, so called, with great difficulty, or to put it in language more in keeping, with far less certainty. The pumping losses increase with the speed, but they are sufficient in poorly made motors to defeat starting on the spark, so called, owing to the feebleness of the force which it is possible to realize when the compression is limited to that which comes from boiling gasoline in the presence of enough air to provide the oxygen to produce a burning mixture, excepting in a motor's cylinder. Likewise, in a motor which is well made, even assuming that all the parts are so nicely fitted that friction is reduced to a very low point, if the cold compression is high, as it will be, that is to say, the compression which will come as soon as the motor begins to rotate, due to the fact that one piston will make its compression stroke, while another is on the power stroke, the power required to equal the force of the generating compression will be greater than the power which can be wrung out of a feeble explosion such as that which comes from igniting the mixture, residuum in character, as it will be found in the cylinders after the motor is shut down and allowed to stand until the temperature falls to the level of the surrounding, especially if the weather is below, in point of temperature, that which checks with the boiling point of gasoline.

Residual Compression Not Very Dependable

The briefly put discussion (number 2201) which precipitated a flood of replies, may be regarded as in accord with the facts, or not, just as point of view is taken. Confining the further discussion, for the moment, to the performance of a motor, allowing that it will, or will not start on the spark, assuming that residual compression is the source of the force available, then, it is believed, certainty of action is cast to the four winds, and speculation reigns. But it will fail to reach even the level of speculation, just so soon as the temperature falls below the boiling point of gasoline, for, even if the gasoline is in the vapor state, and present in sufficient quantity to permit of starting when the motor is shut down, the gasoline will condense in the course of a little time, when it will remain in the liquid state just so long as the temperature keeps below the temperature of boiling of the gasoline.

As a rather far-fetched illustration of the true situation then, let it be taken for granted that "earthquakes" are of the phenomena which human beings accept as possible, and even regular occurrences. Let it even be assumed that they do, at times, manifest the force sufficient to raise the habitations of man. Despite this threatening situation, even in view of the formidableness of the force, man goes right on putting up "skyscrapers." Transferring this simile to motor work, is it not reasonable to

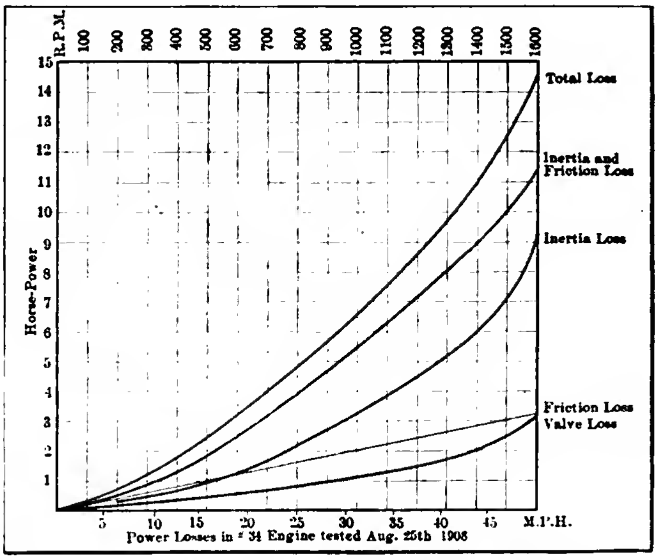

Fig. 1—Curve plotted to represent pumping losses in gasoline motors and subdivisions of such losses

inquire as to the reason why automobile builders provide cranks without fail; is it not a fact that starting on the spark, so called, like earthquakes, is just a little uncertain?

Since it is true, undeniably so, that starting on the spark is dependent upon the temperature, and temperature is a variable depending upon the seasons of the year, altitude, and local weather manifestations, then, in the light of cold hard facts (let us admit) unalterable facts, why say that a motor has the facility of starting on the spark?

Is it not better to stick to the main truth and merely remember that, if the weather is warm, or if the motor is in a heated condition, starting on the spark, so called, will be possible if the "pumping losses" of the motor are not excessive? Were it possible to so design motors that they would be independent of the condtions which respond to natural phenomena, then, and then only, would motor builders be justified in claiming that their motors would start on the spark, but does anyone think these motor builders would go to the expense of furnishing a starting crank, if they could control the acts of God, subdue the elements, and reverse the law of the conservation of energy?

For the time, space will not admit of going into the question of the characteristics of gasoline further than to conclude by reiterating the mere declaration, as has been made, that gasoline will not burn until it is vaporized, and that it will not vaporize (boil) unless it is heated to its boiling point, and supplied with enough heat to balance its latent heat of evaporation. The further elucidation of these characteristics of the fuel used in automobile motors, in view of the apparent lack of understanding of the same, will be as an agreeable task, to be undertaken at an early moment, as a supplemental statement to what has been said here in support of the fact that "an occasional occurrence is not entitled to the distinction of being termed a rule," nor can the user of an automobile rightly make the broad claim that his automobile will start on the spark, unless he can overcome Natural phenomena and the Laws, which, more than 95 per cent. of the whole time, prevent him from making good his claims.

No Spark Start for These 65 Cars

The futility of depending upon "starting on the spark" was conclusively demonstrated on broad, practical lines at the St. Nicholas Garage, New York City, on May 26.

In the garage there are 65 automobiles of all kinds and descriptions in daily use. Before they were taken out, the chauffeurs, were requested to start their motors on the spark. They all failed to get any result. The cars used for the experimental test comprised the following:

Car	Ignition System	Car	Ignition System
Lozier	Dual	Jackson	Double
Rambler	Double	Pope-Toledo	Coil
Franklin	Coil	Stevens-Duryea	Double
Autocar	Coil	Thomas	Coil
Pierce-Arrow	Double	American Mors	Double
Garford	Double	Pope-Hartford	Coil
Corbin	Coil	Grout	Coil
Selden	Dual	Reo	Coil
Buick 40	Dual	American Roadster	Double
Chalmers 30	Dual	Lozier	Double
Olds 40	Double	Pierce-Arrow 48	Double
Fiat 25	Magneto	Pope-Hartford	Dual
Packard 18	Double	Studebaker	Double
Maxwell	Coil	Aster	Double
Chalmers 30	Dual	Thomas 60	Double
Haynes	Dual	Simplex	Magneto
Garford	Magneto	Ford 6	Coil
Stearns 30-60	Dual	Maxwell	Double
Mercedes 50	Magneto	Elmore	Double
Olds	Coil	Locomobile	Dual
Chalmers	Dual	Studebaker	Magneto
Olds	Dual	Chalmers	Dual
Autocar	Double	Pope-Toledo	Double
Pullman	Dual	Pierce-Arrow	Double
Rainier	Double	Pierce-Arrow	Double
Thomas	Double	Reo	Coil
Stearns	Dual	Studebaker	Coil
Mercer	Coil	Buick	Dual
Stevens-Duryea	Dual	Buick	Dual
Peerless	Double	Marion	Dual
Thomas 50	Double	Cadillac	Double
Winton	Dual	Olds	Dual
Cadillac	Double		

In conclusion, let it be understood that there is no question of the practicability of starting on the spark, no matter which make of automobile is considered, provided the conditions are ripe, but it is not a dependable way of starting, nor is this method to be relied upon at all unless the temperature obtained is that which will boil gasoline.

New Type of Racing Magneto Is Being Used

IF for any reason, such as poor gas, improper spark plug location or a half-dozen possible causes, the flame propagation in a high-speed motor becomes sluggish its efficiency decreases surprisingly as is well understood.

In tests made abroad the arrangement of two spark plugs, operated simultaneously, is found to have a marked effect on the output of the motor, and with this idea in view, a number of foreign racing machines were fitted with two magnetos, each operating a set of spark plugs. But it was found that the very slightest variation in the time of operation of the two magnetos rendered the system useless, because the spark which occurred first ignited the charge and the spark which came at an infinitely small space of time later, still came too late to be of any assistance in starting the flame propagation from two separate points of the combustion chamber. And it was found practically impossible to time two magnetos so that they would operate both plugs at the same instant. Even assuming that the original setting of the magnetos produced the desired result, it was impossible to keep the setting correct, owing to the wear of the mechanism driving the magnetos and also the wear on the interrupter points.

To avoid these difficulties, the well-known German ignition specialists, Unterberg & Helmle, who make the U. & H. type of magnetos, developed a new model of magneto which meets the requirements of racing motor service. In this new U. & H. racing magneto two armatures are employed mounted tandem, and running in the same armature spindle on one shaft. These armatures are fitted with two complete sets of windings, each set consisting of a primary and secondary winding. The most unusual feature of the magneto lies in the employment of but one interrupter to break the primary circuit of both armature windings, this arrangement producing the high-tension current in both armature windings at precisely the same instant. The magneto is equipped with a compound distributor, to which each armature winding is connected by conventional means. One set of plugs is connected with one distributor and the other set of plugs, of course, is connected with the other. Two safety spark-gaps, one for each circuit, eliminate danger of damaging the windings should the cables leading to the plugs be accidentally broken, which is not impossible.

This arrangement overcomes the objections heretofore found abroad and with this new type as shown the principle of operation proves worthy. In this double magneto is also employed the U. & H. non-adjustable interrupter, which eliminates ignition difficulties otherwise due to breaking or sticking of pivots, springs and insulation of the replating parts.

U. & H. magneto with double armature and single interrupter

Elastic Limit of Manganese and Other Bronzes

(Continued from last week.)

pounds per square inch. Had ordinary dividers been used, the values for the cast metals would have been placed between 30,000 pounds and 40,000 pounds per square inch. The strain diagrams from the extensometer tests show the general shape of the elastic curve of the metal, and permit the accurate fixing of the point of inflexion of the curve; the autographic diagrams, however, show not only the actual shape of the curve, but also why there is the uncertainty in the locating of the yield point or point of rapid increase in rate of stretching.

For comparison, the autographic diagram of a piece of commercial "structural medium" steel is shown as No. 1 in Fig. 3. At the scale of the diagram, no inflexion of the curve is seen until it suddenly breaks sharply, actually drops and remains practically horizontal until it finally picks up again. This jog is entirely characteristic of mild steel, and is found to a more or less marked extent in all steels, save perhaps the very hard varieties. There is, however, no break of any sort in the curves obtained from bronze; they are entirely smooth. Somewhere along the knee of the curve, the tester notes that the material is stretching faster; just where he notices it will depend upon the sensitiveness of the means employed to indicate stretch, and upon his skill and sharpness in observation. The jog in the steel curve is indicated simultaneously by the slipping of the dividers and by the dropping of the scale beam of the testing machine driven at constant speed. The scale beam does not drop when testing bronze; the operator finds the poise gradually traveling more slowly to maintain balance, but who can say when the change in rate began?

TABLE 6—HALCOMB STEEL COMPANY TESTS

Autographic Tests All Specimens 1 In. (Approximate) Dia. by 8 In. Long

Mark		9902A	9908A	Q2992A	Q6434A
Number on Curve Sheet......	1	2	3	4	5
Sample	Steel	Cast	Cast	Hot-Rolled	Cold-Drawn
Reduction of area, per cent....	58.6	8.3	14.1	53.2	38.6
Elongation, per cent..........	36.3	27.2	6.6	34.4	25.2
Elastic limit, lbs. per sq. in....	38,000	21,400	22,900	22,800	25,200
Tensile strength, lbs. per sq. in.	60,140	69,700	63,940	71,820	68,500

Commercial Tests (Made at Schenectady) All Specimens 0.5 In. Dia. by 2 In. Long

Sample	Cast	Cast	Hot-Rolled	Cold-Drawn
Reduction of area, per cent............	54.8	22.4	44.9	39.9
Elongation, per cent..................	42.0	14.5	37.5	34.0
Yield point, lbs., per sq. in............	25,000	26,000	30,000	44,000
Tensile strength, lbs. per sq. in........	67,940	70,900	74,780	74,260

It is customary to find the yield point in mild steels, and in fact, in annealed steels generally, at about 50 per cent. of the maximum strength. The yield point in mild steels corresponds, for all practical purposes, with the elastic limit. As the steel becomes harder, due to increase in carbon or the addition of alloying metals, or to heat treatment, the yield point rises rather more rapidly than the elastic limit, although the difference between the two is not so great but that the former may be used in calculations, and the yield point itself is less sharply marked, though still observable if sufficient care is taken. The yield point in steel is accepted as a safe guide to the engineer, in deciding upon the maximum stresses that may safely be permitted in parts designed to carry load.

That no such dependence can be placed upon the so-called yield point, as it is determined upon bronzes, is evident; rather, recourse must be had to the slower but more accurate determination of the true elastic limit if safe data are desired. It is especially noteworthy that the sets found at the minimum values of yield point as usually reported are a very considerable proportion of the total stretch that has taken place in the metal at those stresses, and that sets are found at stresses which are but 40 to 50 per cent. of these reported yield points. Under certain conditions of dead load, a stress of 75 per cent. of the elastic limit is sometimes considered at least not unsafe; if such a load were calculated for bronze, upon the basis of the usual commercial test for yield point, instability of the part so designed would be inevitable.

Hot working of the metal has not materially improved its elastic properties, but has greatly increased its toughness, and probably in an extended series of tests, would have been found to impart uniformity. It is well known that this particular alloy is relatively difficult to handle in the foundry because of its sensitiveness to temperature of pouring and to changes in composition, at least in the sense of impurities in the constituent metals, and because of its great shrinkage, requiring large feeders and sink heads. As in other copper alloys, many of the ill effects of this sensitiveness may be largely overcome by hot working. The data here presented are too meager to warrant lengthy discussion of the effects of cold working of the metal; it is shown that in the case of bars of 1 1-2-ins. diameter, the effects of the cold drawing may have largely disappeared when 1-4 in. of metal is removed, except as shown in a lessened elongation. Neither hot nor cold working cause any change in the elastic curve of the metal; it remains a characteristically smooth curve. In other cold-drawn copper alloys, when tested without removal of surface, the elastic curve usually presents a much sharper bend at the knee than is found in the cast metal, or in the same metal when annealed; the same would probably be found with manganese bronze if tested as drawn, without turning. Cold-drawn metal, except wire, is seldom used without removal of the surface to provide means of fastening, and it surely is safer to test it as it is used rather than in the perhaps fictitious condition of strength due to skin hardness.

These results do not constitute a new discovery. In the literature of testing engineering, references may be found with direct bearing on the subject; but in these days of rapid progress and short-cut methods. much that is old, or that may be found only by search, is apt to be forgotten or overlooked. Comparatively few laboratories have autographic machines, and the use of the extensometer with a specimen only 2 in. long is not very satisfactory because of the small extension of so short a length of material under stress. Many otherwise well equipped laboratories have no extensometer. So much of experience in testing materials is based upon work done upon iron and steel that it was perhaps a natural assumption that the characteristics of these metals would also be found in bronzes and similar alloys and hence that methods of testing used successfully with one would yield equally safe results when applied to the other. Test results which are misleading are exceedingly dangerous; they induce a false sense of security which may result in the failure of structures and lead to the condemnation of a material which would be perfectly satisfactory if properly applied and not unwittingly abused.

Engineering Digest

A carefully abstracted digest of accounts of engineering activities as they are reported in society transactions and technical papers throughout the world.

An Imaginary Automobile for 1915.—So as to convey gently a hint to manufacturers with regard to the improvements which might be incorporated in the productions of the industry at any intervening time, the author presents his idea of the supposedly standard automobile chassis of five years hence. All side levers have disappeared, so as to leave the entrance to the driver's seat at both sides of the vehicle entirely cleared of obstructions. The steering column carries the speed lever and a finger piece, which serves only to block the rear wheel brake pedal. There is also a front wheel brake pedal, but no brake on the transmission, such being required only by "scorchers," says the author. The dashboard is converted into a gasoline tank, giving sure-enough gravity feed to the carbureter, which is placed in a warm spot between the two batteries of the eight-cylinder motor, so as to require no water heating. The wheels are wire spoked, with large pneumatic tires, which the prophetic designer contemplates to operate with pressures of 9 pounds per square centimeter, viz., 58 pounds per square inch. The drive is by a rigid shaft from the speed change box, through torsion tube, to a single flexible joint connecting with a worm meshing with a helical gear, the rear end of this drive being suspended from two cross members of the chassis in a casing also inclosing the differential gear, which drives the rear wheels through a suspension consisting of universal joints *V* on the inner ends of the wheel drive shafts, and the braces *X* which are hinged to the differential casing, and with their outer ends form collars supporting the drive shafts close to the wheels. The suspension, which takes the place of the "rear X," is the real novelty in the author's conception. It is readily understood with reference to the side and plan views shown in the illustration. *O* is the fixed axis of this suspension. *P* are bell-lever struts, the horizontal arms being radius struts for the wheel shafts, while the vertical arms transmit road shocks and motions to the extension-springs *R*, whose tension is adjustable by a screw at *T*, where the springs have their front support through the member *S* mounted on the torsion tube enclosing the drive shaft *N*. (The author's conception seems a little hazy at this point.) The brake rods or wires *j* are balanced in action by the sleeve on the suspension axle *O*. The rear portion of the frame is arched over the rear driving system to give room for the spring action, but it seems that the author is willing to accept a somewhat peculiar participation of the rear wheels in all spring movements, or else he has overlooked this consequence of his design.

The motor is conceived as an 8-cylinder, 45 degree V-mounted, valveless creation supporting the radiator above it, on the thermo-syphon plan; and a centrifugal blower is on or in the radiator. The illustration shows other points. *Ja* stands for an oil gauge which is the only external evidence of the oiling system, excepting *Pa*, which is the cover of the internal oil pump. *Vi* is the drain. *E* is the tubular radiator, *Co* the tubes holding ignition wires. *Mg* is the high-tension magneto, *Ca* the carbureter with two independent jet chambers. *Se* are the supports and water connections for the radiator. Instead of the customary curved under-pan, the sheets *To* connect the false chassis *Fc*, on which the motor is mounted, with the frame reaches *Lo*.—L. Baudry de Saunier in *Omnia*, May 7.

The Ageron Self-Starter Mechanism, also adapted for inflating tires and blowing alarms, contains features worth noting. Apart from the main purpose of the device, the shape of the extension spring *c*, Fig. 2, attracts attention by the rounded ends, produced by diminishing the diameters of the terminal convolutions. This shape is seldom seen in American automobiles, though neat in appearance and rather well calculated to convey to the beholder an impression of finished and deliberate design, partly because it cannot be connected up so readily as the customary extension spring with the single-wire hooked ends, and therefore presupposes that the connections are shaped and placed in their position at the same place where the spring is made. The twice-wound pulley *a* in Fig. 2 would not be practicable, if it were intended to be rotated for more then about two-thirds of one revolution, as the cable would be practically certain to climb the pulley flanges, unless some remarkable material were found permitting the cable to slide readily transversely of the pulley-face while yet pulling without slip tangentially. But comparison of the length of the compressed-air piston stroke with the diameter of the pulley shows that the cable is not expected to turn the pulley much more than two-thirds of one revolution.

Fig. 2 shows the principle of operation for the self-starter mechanism, while Fig. 3 shows a complete installation, including an air-compressor to be connected with the motor, the air-conduits of seamless copper tubing, which is of 9 millimeters interior and 12 millimeters exterior diameter, and the "distributor" *I*, affixed to the dashboard, which is essentially a multiple air-switch, containing the check valve for the compressor, the pressure gauge, the safety valve with whistle alarm, the self-starter cock, the general release cock, a turn cock for tire inflation and another to the alarm siren or horn *K*, in Fig. 3.

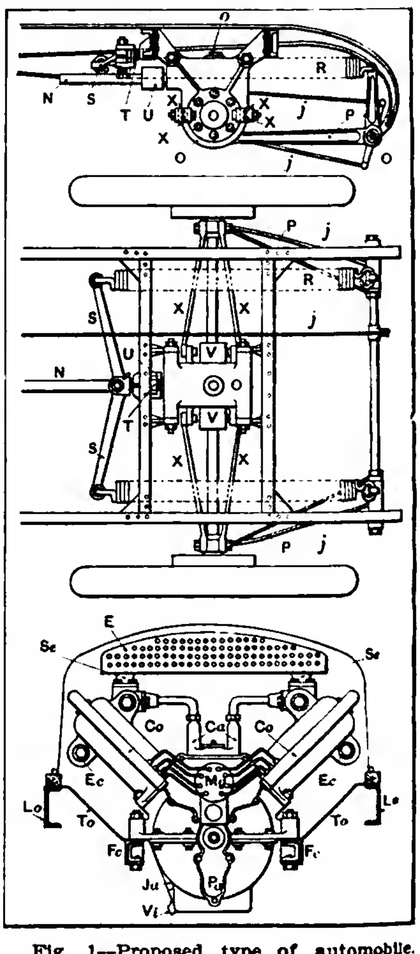

Fig. 1—Proposed type of automobile which the designer thinks will hold sway in about the year 1915

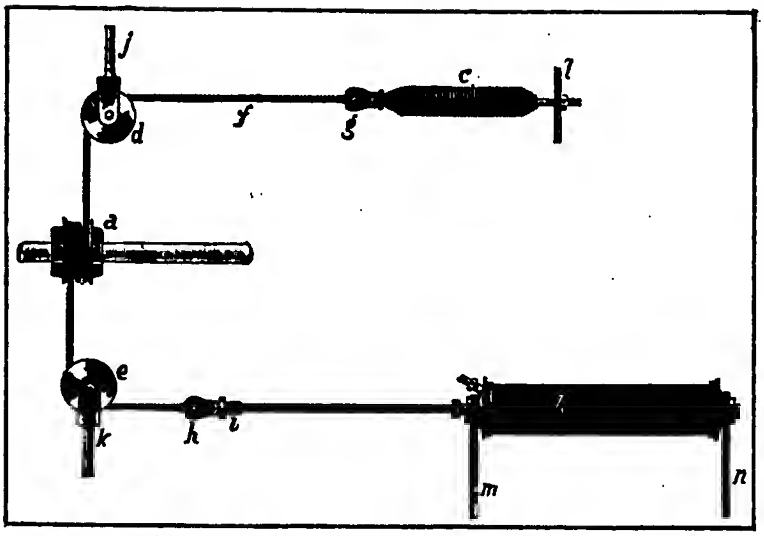

Fig. 2—Diagram of self-starter mechanism acting upon clutch shaft by means of compressed air

The pulley *a* in Fig. 2 is secured to the intermediate shaft between the clutcb and the speed change and is provided with an interior free wheel. The cable *f* is secured at one end by the clip *g* to the retractor spring *c*, at the other end by clip *h* to the piston rod of the cylinder *b* and is guided by idlers *d* and *e*. The letters *j*, *k*, *l* and *mn* represent the means for securing the various parts to the chassis. For starting the motor, air is admitted to cylinder *b*, which pushes the piston toward the bottom of the cylinder; the cable pulls the pulley and the intermediate shaft around, and the motor is started, if the clutch has been previously engaged. The spring *c*, which has been extended by this action, thereafter pulls the piston back to its starting position and the mecbanism is ready for operation again. In order to economize on compressed air, a special device, unexplained by tbe author, and designated as a regulator-economizer, forms part of the air tube leading to the cylinder *b*, as shown at *J*, Fig. 3. It regulates the admission of air from the tank *B* to the cylinder *C*, apparently by check valves.

In Fig. 3, *A* is the compressor, *B* the air tank, *C* the self-starter cylinder, *D* the free-wheel pulley, *E* the steel cable, *F* the retractor spring, *G* the clips for attaching tbe cable, *HH* the idler pulleys, *I* the "distributor," *J* the "regulator-economizer," *K* the siren and *L* tbe lever for operating the compressor. The compressed air may also be used for operating a jack of special design in case of necessity. It is unfortunate that it is not explained how the compressor is disconnected. As shown in Fig. 3 it is operated by sprocket and chain from the intermediate shaft, the same on which the free-wheel pulley is mounted. No mean are indicated in the article for applying the device to a shaft-drive automobile.—*La Vie Automobile*, April 9.

Superficial optical tests of metals, especially steels, forms one of the subjects in a series of articles by Jules Vinsonneau concluded in the April number of *La Technique Automobile et Aérienne*. As a critical and analytical review of the methods employed in France in the steel mills and in the laboratories, and a summary of the defects which may occur in materials, the article repays perusal in its entirety, the author advocating a much higher degree of uniformity in the dimensions of test pieces than is usually insisted upon. With regard to superficial optical tests which are frequently recommendable, especially when the more thorough methods are unavailable for one reason or another, the author dwells on tbe value of tbe darkened chamber in which the fragment of metal is subjected to scrutiny under strong ligbt, and also on the need of examining tubes interiorly as well as on tbe outside. Only a few quotations can be offered. "They speak of silicon bronzes, of manganese bronzes; tbey praise special aluminum bronzes, etc., which give results in tensile and bending tests, comparable to those obtained with irons and steels!!!"

"Wbat kind of tests were they? Were they made with thin and long test pieces or with thick and short ones? With what irons and what steels have these various bronzes been compared. Were the comparative tests made with test pieces of the same dimensions? Were the same prisms used for the bending and for the shock tests? Were the tests of fragility conducted with the same lapses in accuracy? A day will come, no doubt, wben these uncertainties will be removed," nor will it be surprising if the progress desired is rapid.

"Cornut says: 'If we suppose that a piece of steel or iron is subjected to a continuous stress, slow and progressive, it is well understood that this stress is transmitted successively from molecule to molecule, in such manner that all the molecules are practically subjected to the same stress. On the other hand, if the stress is sudden, instantaneous, it is understood that all tbe molecules of the body cannot get time to communicate and distribute this stress, and that the first molecules affected may be loosened right in the beginning, while other molecules have borne no stress at all. The metals consequently may present very different qualities accordingly as they are subjected to slow or sudden stresses in the tests.'"

"In his note to the *Académie des Sciences*, Frémont expresses the following thesis on fragility: 'A steel is fragile, brittle, or not brittle, accordingly as the ratio between the tensile elastic limit and the elastic limit for compression is smaller or larger than 1.'

"At the congress of mechanics in connection with the Exposition of 1900, when it was demanded that the optical test of metals should be made obligatory, the matter was put to the test of a vote, after the theoretical and practical reasons for the proposition had been thoroughly discussed. Both the novelty of the method proposed and the fear of encouraging rejections of metals from the mills militated against it, and nevertheless it obtained a vote of 15 for and 19 against it. Under the circumstances this vote may be considered proof positive of the genuine interest attached to optical test methods."

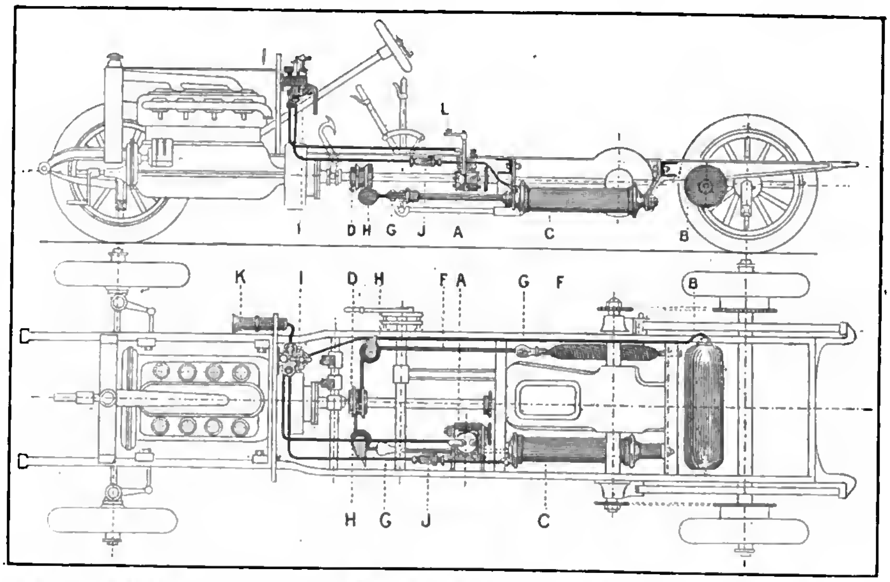

Fig. 3—Installation of air compressors and air tank in connection with self-starter mechanism acting upon clutch shaft and devices for inflating tires and operating alarms

Questions That Arise

A series of practical questions relating to the automobile, its parts, and their functions, which arise upon various occasions, together with easily understood answers to the same.

[42]—Why introduce such a complicated device as a differential gear system if the difference as above found is so slight; surely it would not damage the tires so very much to allow of this amount of slipping when a turn is being made?

True, the amount of slipping is not nearly so great as that which is likely to follow reckless driving with its skidding and the slipping which comes in every time the brakes are locked, or when the power is applied suddenly. But this continual skidding does damage the tires, and in the same way they would be rapidly depreciated were there no differential gear. On the other hand there is a more important reason for having a means which will prevent skidding when a car is going around a curve. The condition designated as "inertia" can not be ignored; according to the first law of Newton, when a car is at rest, it will remain at rest; or if in motion, it will move uniformly in a straight line until acted upon by some force.

When an automobile is in motion, if it is diverted from its straight path, it tends to travel in the straight line with the same force as that which its inertia represents, and if one of the wheels must skid, which will be true if there is no differential, it follows that the force of inertia will be more likely to overcome the tractive ability of the remaining wheel (at the rear end of the automobile), which, if it does, will cause the automobile to behave badly; an accident may follow.

[43]—How may this force of inertia be estimated?

If it is assumed that the tractiveability of the wheels with the ground is destroyed, it follows that the centrifugal force of the mass will be a proper estimate of the inertia component.

Centrifugal force is determined as follows:

Let

R = radius in feet of the curved path:

F = centrifugal force in pounds;

W = weight of the body in pounds;

N = number of complete revolutions the body must make in its circular path in one minute of time;

v = linear velocity of the center of gravity of the body in feet per second;

g represents the force of gravity = 32.16 as taken.

Then,

$$v = \frac{2\pi RN}{60}$$

$$F = \frac{Wv^2}{gR} = \frac{Wv^2}{36.16R} = \frac{W4\pi^2RN^2}{32.16 \times 3600} = \frac{WRN^2}{2933} =$$

$$= 0.0003410\ WRN^2.$$

[44]—What is the numerical value of the force of gravitation? Is it the same everywhere over the surface of the Earth?

The force of gravity, designated in text books as g, increases with the latitude, and decreases with the altitude. At Paris, France, the latitude is 48° 50′ N., and the value of g is 32.181; the altitude taken being that of the sea level, which is 0.

According to Everett, the constant g may be determined as follows:

$g = 32.173 - 0.082 \cos 2$ lat.—0.000003 height in feet.

In the United States it is common custom to take 32.16 as the value of g.

[45]—What is the reason for considering the force of gravity in connection with automobile work?

Everything that moves is retarded or accelerated by the gravitational force; going up hill it is retarded; going down hill it is assisted; on the level it is still under the influence of gravity and the force exerted must be reckoned with.

[46]—In what way does the force of gravity interfere with the travel of an automobile when the road is level?

Since, through the action of the force of gravity, a body will fall to the ground if it is free, the same force will act when the body is resting upon the ground, and with the same force; the body tends to fall all the time, and if the surface of the earth interferes with its further migration, a pressure will be exerted between the surfaces; if there is a pressure there will be friction; if there is friction it will take an effort to move the body against the resistance offered.

[47]—But an automobile is equipped with wheels; it rolls along the roadway; why should gravity have anything to do with it?

For the very simple reason that the rolling of the automobile along the roadway does not destroy the force of gravity. Were there no force of gravity, on the other hand, the automobile would not go either up hill or on a level. The reason for this is that there would be no traction; the wheels would slip and spin around, but the automobile would not go ahead. Traction, at it is termed, is but a manifestation of the force of gravity; when it is said that there is a certain number of pounds pressing on each traction wheel, which, considering the coefficient of friction, or adhesion, enables the motor to spin the wheels and cause the automobile to roll along the roadway, it is all due to gravity and involves the value of g at the time and place.

[48]—To what extent does gravity aid in the process of running an automobile?

As a practical example of the value of the force of gravity in the propulsion of an automobile, it is first necessary to determine the weight resting upon the traction wheels and then learn the value of the adhesion of the tires to the roadbed. Adhesion is variable, depending upon the nature and condition of the tires, also the nature and condition of the top dressing of the roadway.

It is common practice to assume that 60 per cent. of the weight of an automobile rests on the two rear wheels; weighing the automobile. then, is the first requisite, when the following will hold:

$T = W \times 0.60^2$

Which, for a 2,000-pound automobile, represents:

$T = 2000 \times 0.60 \times 0.60. = 720$ pounds on two wheels, 1-2 of which, 360 pounds, will represent the traction of one-half of the total weight.

Knowing the value of T (the traction), the power which may be utilized at the point of contact of each road wheel may then be determined at any speed of rotation which does not alter the tractive ability. Unity may be taken for the speed, in revolutions per minute, and the following will hold:

$$\text{H.P.} = \frac{2\pi RST}{33{,}000} = \frac{6.28 \times 1.5 \times 1 \times 360}{33{,}000} = 0.1028 \quad \text{horsepower}$$

per revolution of the traction wheel, up to the point where traction is diminished by the conditions which increasing speed interposes.

In the above:

$\pi = 3.1416$;

R = radius of the road wheel in feet = 1.5 foot in this example;

S = speed of rotation of the road wheel in revolutions per minute = 1 revolution as taken;

T = traction in pounds, taken as 360 in this example;

33,000 = foot-pounds per horsepower.

[49]—This seems like a small amount of power; is it enough for the purpose?

It must be; automobiles do run; it is all the power that can be utilized in view of the force of gravity and the coefficient of friction of the materials used, considering the tires and the roadbed. Assuming that the road wheels travel at the rate of, say, 300 revolutions per minute, the power which can be utilized under these conditions will be as follows:

$$\text{H.P.} = \frac{6.28 \times 1.5 \times 300 \times (360 \times 2)}{33{,}000} = 61.66$$

[50]—How fast will the automobile go under these conditions?

It is extremely difficult to predict. The 1.5 foot radius taken in the formula demands the use of 36-inch tires in the wheels, and $36/12 = 3$ feet diameter, which, multiplied by $3.1416 = 9.42$ feet travel of the automobile over the roadbed for each revolution of the wheels. $9.42 \times 300 = 2{,}826$ feet per minute, and,

$$\text{miles per hour} = \frac{2{,}826 \times 60}{5{,}280} = 32.11.$$

[51]—Would it take so much power to drive a 2,000-pound automobile at the rate of 32.11 miles per hour on a hard level roadway?

No. There is no statement made in relation to the amount of power it will take to drive the automobile; what was ascertained is the amount of power which could be utilized in view of the traction available, and at the speed named.

[52]—How much power would it take?

Primarily, were it to take more than the amount above named, the automobile would not run; this is the point which is brought out by the above discussion, not forgetting that it explains something of the relation of gravitation. Just how much power it would take to drive a 2,000-pound automobile at the rate of 32.11 miles per hour on a hard, level road is difficult to state. If the internal loss, due to friction in the transmitting mechanism, etc., is 33 per cent, then, $61.66 \times (1 - 0.33) = 41.21$ horsepower is left to drive the automobile.

Having deducted the friction and other internal losses in the transmitting mechanism, it remains to account for "wind resistance," and such other factors as will add to the power requirement, after which it will be possible to fix upon the power the automobile will use, in which it will be necessary to include:

DISTRIBUTION OF POWER REQUIRED TO DRIVE

(a) Wasted at the point of contact of the tires.

(b) Used in deflecting the chassis springs in the process of affording good riding qualities.

(c) Dissipated in vibrations, deflection of all the members in the composition of the automobile.

(d) Dissipated in the deformation of the tires; molecular work in the compressed air in the tires, and in deflecting the roadbed.

(e) At every bearing in shearing the lubricant which is placed there to lower the power requirement, and prevent seizing of the metals which compose the bearing surfaces.

(f) In overcoming the force of gravity.

(g) Wind resistance is separate; increases with the extent of surface; is more or less dependent upon the form of surface, and is markedly affected by speed.

In view of all of the above factors, it is quite possible to state the power required for all automobiles; they do not all perform exactly alike; there is a marked difference between them, but it may be a fair estimate, considering average conditions, to put the rate of power required as approximately 150 watts per ton-mile (1 watt is equal to 1-746 of a horsepower). This would be the draw-bar pull, to which must be added the losses which come as the increasing speed brings on its quota of losses from all the sources as above set down.

There must still be a reserve of power in order to compensate for the effect of gravity on a hill; if a weight will fall to the ground, as it will under the action of gravity, it follows that to elevate the weight demands the expenditure. It is all the same whether the weight is in the form of a ton of coal or an automobile; it makes no difference whether the weight is lifted in an elevator or rolled up a hill in the form of an automobile or other vehicle.

METHOD OF LUBRICATION

[53]—What is friction?

According to Rankine, it is that force which acts between two bodies at their surface of contact so as to resist their sliding on each other.

[54]—How is friction characterized; is it designated in more than one way?

Yes. There is friction of rest and of motion, and further subdivisions as follows: (a) rolling friction, and (b) friction of solids.

[55]—What is friction of rest?

The force required to start a body sliding is called the friction of rest.

[56]—What is friction of motion?

The force required to continue a body in motion at a constant rate after it is started is called the friction of motion.

[57]—What is rolling friction?

The force required to roll a cylinder or sphere on a plane surface is called rolling friction.

[58]—What is friction of solids?

It was Rennie, in 1829, who experimented on the friction of solids, mostly under conditions of unlubricated (dry) conditions, from which the conditions as follows were reached:

(a) The law of solid friction differs with the character of the bodies rubbed together.

(b) The friction of fibrous material is increased by increasing the extent of surface and by time of contact, and is diminished by pressure and speed.

(c) With wood, metal, and stone, within limits of abrasion, friction varies only with pressure, and is independent of extent of surface, time of contact, and velocity.

(d) The limit of abrasion is determined by hardness of the softer of the two rubbing surfaces.

(e) Friction is greatest with soft, and least with hard materials.

(f) The friction of lubricated surfaces is determined by the nature of the lubricant rather than by the solids themselves.

[59]—What is the law of unlubricated friction?

According to A. M. Wellington (*Eng. News*, April 7, 1888), a fair expression of unlubricated friction is as follows:

(a) The coefficient of unlubricated friction decreases with velocity.

(b) Is maximum under conditions of minute velocities.

(c) Falls very rapidly with minute increases of minute velocities.

(d) Continues to fall, but at a very much decreased rate, as velocity departs from minute velocities.

(e) At higher velocities the coefficient is more nearly in accord with the conditions which obtain with lubricated friction.

Why Do Not All Use Friction Drive?

Editor THE AUTOMOBILE:

[2,275]—Under this caption THE AUTOMOBILE of April 14 printed four questions as follows:

1. "Why do not all automobile manufacturers use the friction transmission instead of selective or planetary, and do away wtih the disc or cone clutch, etc?"
2. "Is not the friction transmission more desirable on account of obtaining any speed from zero to limit on high gear?"
3. "Does not a car with friction transmission get more power delivered to the wheels than a car with any other kind of transmission of equal horsepower?"
4. "Is it not cheaper as to wear and cost of replacing to have a friction than a gear transmission? R. F. HENRY, Jr.

Palm, Fla.

The reply to this states that you "doubt if the average user of this gear used more than three or four of the speeds available." The very fact that the operator has at all times the exact "gear" or "speed" to give the best results explains why a good friction-drive car can run away from most gear-driven automobiles on steep hills and on bad roads, even though the gear-driven car has the more power. The operator of a friction-drive car can stop on a steep hill and upon starting can gain speed much more rapidly than most gear-driven cars with double the power, for the reason that he can increase his "gear" by such easy stages and with so much facility and promptness that he beats the "other fellow" to it.

You further state that "friction transmission of the simple disc type is never on high gear; that is, in the sense that a car with direct drive on the high can be." We are somewhat at a loss to understand how you arrive at this erroneous conclusion. Further on you state that "the friction disc must be replaced every few thousand miles." Our files contain hundreds of letters which prove conclusively that this is not the experience of the average user. Quoting from a few of these:

"I have run my car 11,000 miles and am unable to see that the disc is worn to the slightest extent. The filler, I believe, will be good for at least 3,000 miles before having it renewed"——

"The disc on my car is in first-class condition and the same filler is still on the car which I purchased from your agent a year and a half ago. The car has run a little over 6,000 miles, and I expect to have to apply a new filler in the near future."

It takes a handy man from thirty minutes to an hour to apply a new filler. The cost of this filler is about $3, so that you were right in your statement that the expense is small.

We feel in justice to the users and manufacturers of the friction-drive cars, that this reply should be put before them with the same prominence you gave the article referred to above.

Is It Right to Run On a Retarded Spark?

Editor THE AUTOMOBILE:

[2,276]—I find that I can slow my motor down by retarding the spark, but the radiator then steams. Should it? SUBSCRIBER.

Erie, Pa.

No. Running on a retarded spark is the best way to induce steaming of the radiator, and it has the further great disadvantage of causing the exhaust valves to warp so that they will have to be ground in. Adjust the spark to the speed of the motor, always in the advanced position if good result is wanted. Retard the spark a little when cranking to prevent a "kick back."

Is Doped Fuel as Good as It Is Said To Be?

Editor THE AUTOMOBILE:

[2,277]—1. Is there any fuel which can be used in automobile motors that will give more power and speed than automobile gasoline?

2. What is an "air lock" in the gasoline piping system?

Great Bend, Kan. SUBSCRIBER.

Composite fuel has been used to some extent; it may give a little more power under well defined conditions; it is dangerous to handle, and it is almost sure to damage the motor. THE AUTOMOBILE does not recommend its use.

An air lock in the piping system of the fuel system is precisely the same as the same trouble in a water system. To avoid it, so pipe the gasoline that there will be a "hydraulic grade." This condition will be present if water, after it is poured into the system (gasoline will do) will all flow out at the other end; there should be no low point where some of the liquid will settle and form a trap.

Method for Amateur to Vulcanize Patches

Editor THE AUTOMOBILE:

[2,278]—Will you please say through the columns of your paper which is the best method for the amateur to vulcanize patches on inner tubes, use raw rubber patches and vulcanizing cement, or use regular vulcanizing patches the same as used in cold patching and vulcanize with vulcanizing cement? W. J. MOORE.

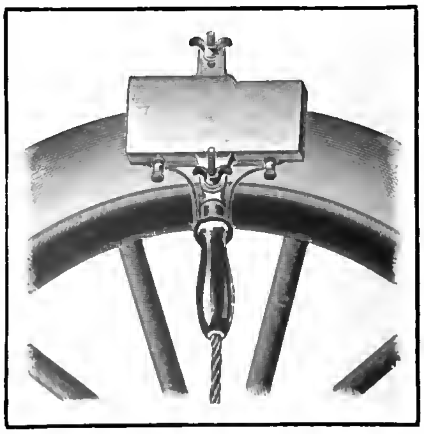
Caro, Mich.

There are two methods available to the amateur:

(a) The acid cure. When the patch is applied in the regular way, it will not stay on, because the cement is "green." Supply men have for sale acid which has the virtue of doing the work of vulcanizing the cement which is used for sticking patches in place, and, from service, it would seem to be efficacious.

(b) The illustrations here afforded depict a type of vulcanizer which works on the principle of heating at the desired temperature (250 to 275 degrees Fahrenheit) for a sufficient length of time to accomplish the purpose. This particular type of vulcanizer is made on the principle of the electrical rheostat, and when the electric current is applied, heat, at the required temperature, is generated, so that the amateur will be in a position to accomplish the vulcanization, if he will but use the vulcanizer, applying it in the manner as herein depicted.

It is not necessary to use electricity as a source of heat; steam, at a sufficiently high pressure to afford the right temperature, is used in the manufacturing process, so that there can be no question as to its capability, but it is something of a problem to use steam under the conditions which obtain when a repair is to be made, and for this reason the electrical equipment is preferred. As to the relative value of the two processes herein described, there is nothing to be said, excepting to point out that the heat method, using electricity, or any other suitable means, is the more natural way, and its best recommendation lies in the fact that it is used in the manufacture of tires, but it is first necessary to prepare the tire for vulcanization.



Vulcanizer in place ready to turn on heat

The remaining important matter is to see that the cement is of the right grade, and that the tire surfaces are scrupulously clean before any attempt is made to apply the patch. In conclusion, it is urged that repair work be started directly a tire shows that it is in need of attention. If the fabric is left uncovered dampness will creep in and "mildew" will follow.

Exact Definition of a High Tension Magneto

Editor THE AUTOMOBILE:

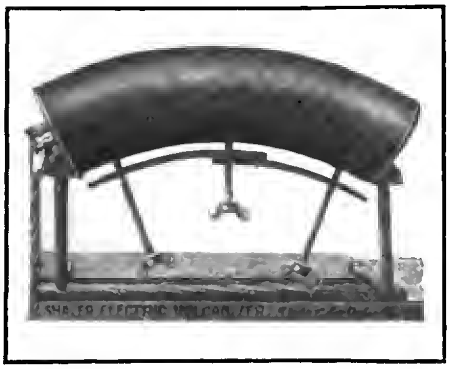
[2,279]—1. Please state the difference between a high and low-tension magneto.

2. What is the relation of a magnetic plug to either of these magnetos? A. P. L. DOHME.

Baltimore, Md.

1. The high-tension magneto is so designed that an auxiliary coil is not necessary; the high-tension current is impressed on a secondary winding which is placed on the armature of the magneto, over the primary winding. In the case of the low-tension magneto, it has but one winding on the armature and a wide-spark mechanism, placed in a cavity connected to the combustion chamber of each cylinder; the hammer and anvil of the mechanism "draws" an arc at the right time by opening the circuit.

2. In the magnetic plug mechanism, magnetism is used to cause the hammer to reciprocate, and the arc is drawn similarly. The advantage derived from using a high-tension magneto, in addition to the energy afforded, lies in the fact that the spark does not have to be advanced so much as when a coil is used; the "lag" is less in the case of the magneto with all windings on the armature of the magneto. It is "lag" which interferes with efficacious work, and in the manufacture of magnetos, the makers employ ways to eliminate time factors.



Healing a wound on the tread of a tire

A Number of Questions Including Block Motor

Editor THE AUTOMOBILE:

[2,280]—Here are a number of questions I would like you to answer. I take this opportunity to let you know how much I appreciate your paper. I think it is the best paper in the field.

1. Is the block construction desirable in a 5 1-4 x 6 motor; if not, why not?

2. What is the matter with a spherical combustion chamber and an overhead camshaft?

3. Are the advantages great?

4. I have a friend who claims that he has a carbureter with an adjustable nozzle, and that he realizes more power by increasing the quantity of gasoline the situation demands. What is the reason for this? I have always thought that it was most difficult to adjust the flow of gasoline.

5. Can splash be relied upon to lubricate a motor?

6. In a book I came across the statement that a radiator can cool too much. Most people believe that a cool radiator is a good thing to have. What is the real situation?

7. I would like your criticism of the motor as follows:

Bore and stroke, 5 1-4 x 6 inches, respectively.
Compression 70 pounds per square inch, absolute.
Horsepower rating (at 1,000 revolutions per minute) 44.
Compression volume 54 cubic inches.
Mean effective pressure 80 pounds per square inch.
Valves 2 1-4 inches in diameter and 9-16 inch lift.
Crankshaft diameter (three bearings) 2 1-4 inches.
Flywheel 16 inches in diameter.
Flywheel weight 66 pounds.

8. What would be the lift of the valves were they 3 inches in diameter?

9. What would be the length of the connecting rod? Would 12 1-2 inches between centers be enough?

10. Would a fan in the flywheel be sufficient, considering thermo-syphon cooling? R. C. GRAHAM.

W. La Fayette, Ind.

1. The block construction would add to the weight, for the reason that the distance between main bearings would have to be allowed for; twin cylinders are used when three main bearings are employed.

2. Nothing the matter with a spheroid combustion chamber; it offers the least flame-swept surface, hence requires the least cooling surface in the radiator for efficient work. The overhead cams will be noisy if the work is not well done. Good work can be done, and some of the makes of motors on the market are satisfactory in this respect.

3. The advantages are great enough to attract a school of designers who are looked upon as alive to the best situation—it is one good choice in motor designing.

4. Your friend may have what he claims; why not examine the carbureter and see if it is any good?

5. The splash system of lubrication is much used, and it works well.

6. It is possible to have a radiator that will do too much cooling; it is rarely ever approximated in actual service. No designer considers the chance of a too efficient radiator as more than a very remote contingency.

7. Bore and stroke are all right. Compression is a little low; add five pounds. Rating is too low. Fix the compression volume to afford a compression (cold) of at least 75 pounds per square inch (absolute).

8. The valves would barely break off of the seats.

9. The length, 12½ inches, would be a little long for the connecting rods, but it would not be objectionable in the presence of good designing; 11½ inches would be a low limit, perhaps.

10. The fan in the flywheel could be made of sufficient capacity to do the work; it would be necessary to have a tight hood, and the under-pan would have to fit also. This is a detail of more than a little importance; if the air leaks through the pan it will do no cooling.

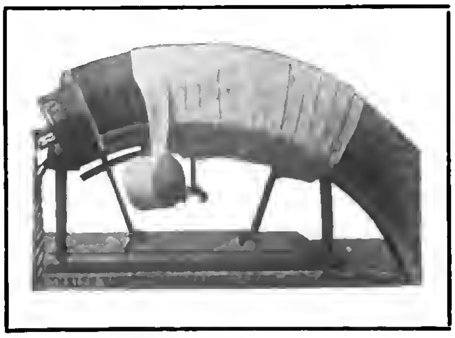
What Is the Best Lubricant for Transmissions?

Editor THE AUTOMOBILE:

[2,281]—Will you state the reason for the use of heavy lubricant in transmission gear systems, rather than cylinder oil?

Rutherford, N. J. F. E. ROGERS, JR.

Cylinder oil is high priced; heavy grease will do the work, and if it costs less it is advantageous to use it. Then, grease or heavy lubricant is more likely to stay in. Cylinder oil will do the work, besides using a sufficient quantity of lubricant, either hard or liquid, according to preference, maintain the parts so scrupulously clean that the lubricant will do the good that it is supposed to accomplish; it may do harm if the parts are not clean. It is well to remember that lubricant oozing out prevents dirt from migrating in, hence it is a good and efficient seal.



Wrapped tread, using tape to hold repair part in shape during vulcanizing

Discussing Features of Various Makes of Magnetos

By HERBERT L. TOWLE

OWING to an oversight, the article of May 19 on "Some Leading Magneto Details" did not contain an explanation of the wiring diagram of the self-contained high-tension type of magneto which appeared in the May 12 issue as Fig. 17. (See Fig. 5-a.) This diagram is accordingly reproduced herewith. The magneto is distinguished by two particulars: First, the high-tension winding, instead of being applied to a separate coil, is wound over the primary coil on the armature itself. It is carefully insulated from the primary except at one end, where both it and the primary coil are grounded on the armature core. The other end is led carefully insulated to a collector ring mounted on the armature shaft, and a carbon pencil rubbing on this collector ring takes off the secondary current and leads it to the distributor. The other respect in which this type differs from that shown in Fig. 16 is that a condenser is employed in connection with the interrupter to suppress the extra current.

Owing to the fact that the secondary coil of the high-tension magneto is located on the armature itself, it follows that it not only receives an induced current, due to the breakage of the primary current, but itself induces a current like that of the primary coil, but smaller in volume.

Let us now examine some of the commercial constructions used in geared magnetos. First, we will take up what may be called the conventional or standard types of (a) low tension, (b) low tension plus separate coil, (c) true high-tension magnetos. Later we shall note a considerable class of magnetos embodying departures more or less striking from the conventional type, and lastly, a group of unclassified magnetos.

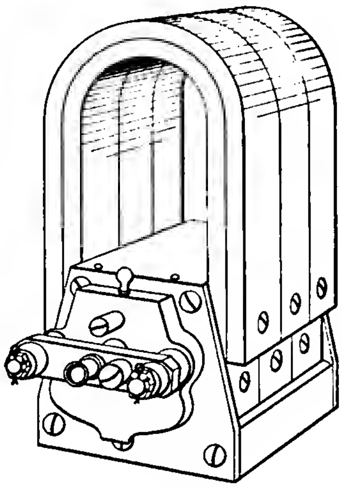
The subject of dual ignition also will be taken up later on. Of low-tension geared magnetos there are at present three given makes, the Bosch, Simms, and Locomobile. Of these the last named is constructed only for use on Locomobile cars.

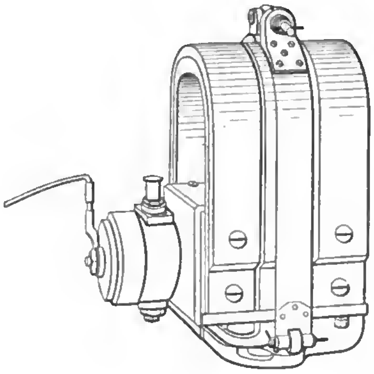
Fig. 1 shows the low-tension Simms magneto in outside view. The horizontal cross-bar at the end is carried by two studs on which it is insulated. This cross-bar carries a central plunger, making contact with the insulated bottom at the end of the armature shaft, as described before. An adjacent screw in the cross-bar serves as a binding post to lead the current to the bus bar and switch.

Fig. 2 shows the Locomobile magneto with the armature removed, thus showing clearly the form of the latter.

Fig. 3 shows the Bosch low-tension magneto in section. This form has plain bearings, but the same magneto is also made with ball bearings. The field magnets 1, armature coil 2, insulated stem 3 passing through the shaft, and insulated terminal 4 containing the spring-pressed contact button 5 are easily recognized. In this magneto the contact portion of the button is carbon instead of steel. The end plates 6, 7 contain little felt oil wicks 8, pressed upward by spiral springs and supplied with oil from the little oil wells surrounding them. These oil wells are filled by removing the covers marked "oil." Leather washers 9 prevent leakage. The ground current is returned from the frame to the armature core through the carbon brush 11, thus rendering it unnecessary for the current to pass through the oil film of the bearings; 16 is the dust cover, and 20 is an insulating washer of steatite or soapstone.

With magnetos of the types shown the spark is advanced or retarded by suitable mechanism acting on the igniters, and there is no advancing device in the magneto itself. The Bosch magneto designed for use with magnetic plugs, however, contains its own spark-advancing mechanism. Fig. 4 shows the end view of this magneto with the cover over the interrupter removed. Lever 10 is pressed by spring 8 into contact with the platinum screw 7, except when the other end of the lever strikes against cams 11. When contact is made the armature is short-circuited. When broken, a momentary extra current goes through the insulating block carrying contact screw 7 and through the spring 14 (turned aside in the drawing to permit removal of the cover plate), and from there through a distributing device, not shown, to one or another of the four terminals 18 18 at the top of the





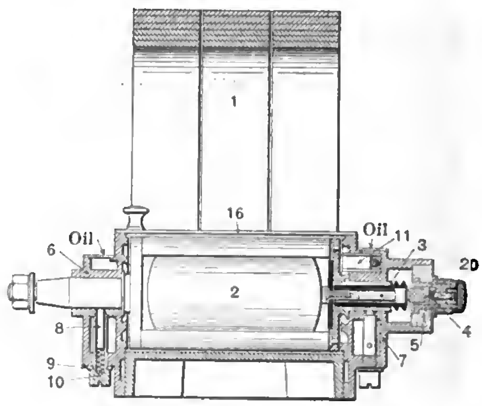


Fig. 1—Outside view of the Simms low-tension magneto. Fig. 2—Locomobile magneto with armature taken off, showing details of construction. Fig. 3—Section of the Bosch low-tension magneto and parts of same

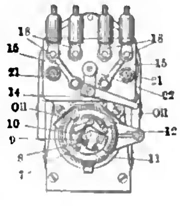

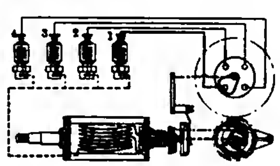

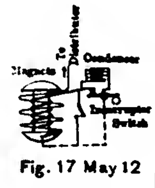

Fig. 4—End view of Bosch magneto containing spark-advancing mechanism. Fig. 5—Showing arrangement of details of same magneto. Fig. 5a—Wiring diagram of self-contained high-tension magneto

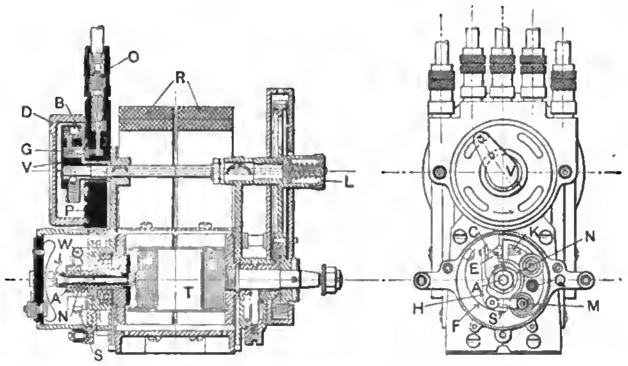

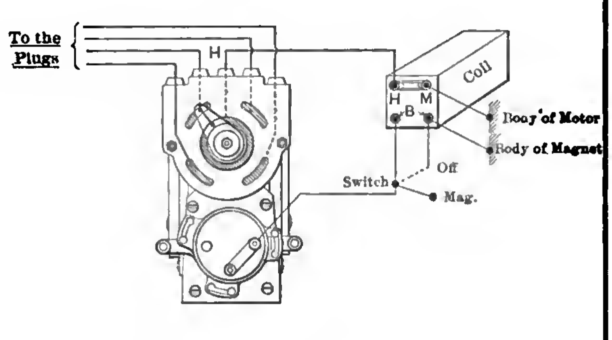

Fig. 6—Eisemann magneto with separate coil for low-tension current and "breaker box" for regulating spark time. **Fig. 7**—Wiring diagram of connections showing also manner of interrupting current

magneto. From the terminal the extra current goes to the magnetic plug screwed into the cylinder. This plug has an electromagnet with fine winding and a delicately balanced contact finger. The electromagnet, energized by the momentary extra current, attracts the contact finger and thereby breaks the magnetic plug circuit, producing a spark at the point of the contact finger. The diagram, Fig. 5, shows the general arrangement. Plug No. 1 is receiving current, and its contact points have just separated. The provision for spark advance alluded to just above is that the barrel-shaped casing from which the lever 12 projects may be rocked through a certain arc in either direction. The cams 11 11 are attached to this casing, and the lever 10 and contact screws turn with the armature.

A modified type of low-tension magneto, known as the rotating screen type, will be mentioned in a later article.

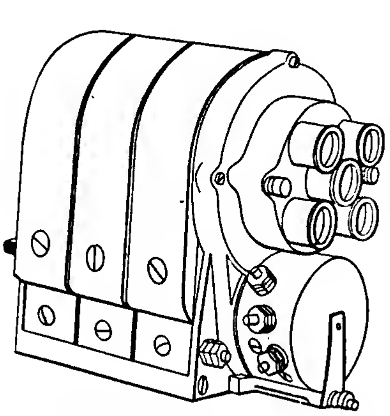
A less simple drawing, but still understandable if closely studied, is that of the Eisemann magneto, Fig. 6, which belongs to the second class in which low-tension current is generated and delivered to a separate coil. The field magnets R and armature core T appear as usual. One end of the armature shaft runs in a ball bearing, the other in a plain bearing similar to those in Fig. 3. The armature current is carried through the shaft by the insulated bolt W to the interrupter whose lever H works against the insulated contact screw E in the usual manner. When the armature short-circuit is broken by separation of the contacts, the momentary extra current passes through the bolt W, through a binding post on the cover plate, to the terminal winding of the outside coil, and thence back to the engine frame and magneto. This extra current induces a high-tension current in the secondary winding of the coil.

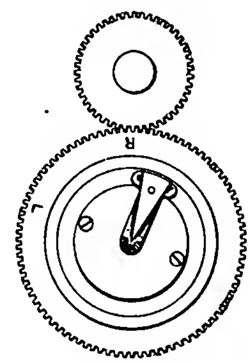
The interrupter is exposed for cleaning by removing the insulated cover plate, and the spark is advanced or retarded by rocking the "breaker box" or casing in which the interrupter mechanism is mounted. This varies the spark time as above explained in connection with the Bosch magneto for magnetic plug ignition.

The high-tension current generated in the coil is distributed to the plugs in order by the distributor running with two-to-one gearing reduction above the armature. The current enters by the terminal O, and is led from there to the revolving carbon brushes G and B, of which the former runs against the inner contact ring in the hard rubber of the distributor, and the second runs against the inlaid brass distributor segments in order. From these segments the current goes to the spark plug terminals. To inspect the distributor the cover D is removed. The hard rubber distributor arm V, carrying brushes G B, is also readily removable, being held on the shaft by a sort of snap clutch, a steel ball engaging a groove in the shaft, as the drawing shows. Fig. 7 is the wiring diagram showing the connections and also showing how the switch interrupts the current by short-circuiting the coil. A condenser built into the coil absorbs the first portion of the extra current and gives it up again in a sudden rush to the coil as soon as the condenser is fully charged.

Fig. 8 shows the Splitdorf magneto in external view. Its principle is that of the Eisemann, but the details are somewhat altered. The high-tension current from the coil enters the central one of the five hard-rubber bushings shown in the distributor cover. These bushings contain carbon brushes, of which the four outer ones receive high-tension current in sequence from a radial arm inlaid into a hard-rubber disc attached to the face of the distributor gear. Fig. 9 shows these distributor details. Fig. 10 shows the wiring diagram, of which the most important feature is that a battery is used for starting, the same coil and distributor serving both magneto and battery. Unlike most battery ignition systems, the battery is not grounded, but both terminals are connected by wiring to the coil.

(To be continued.)





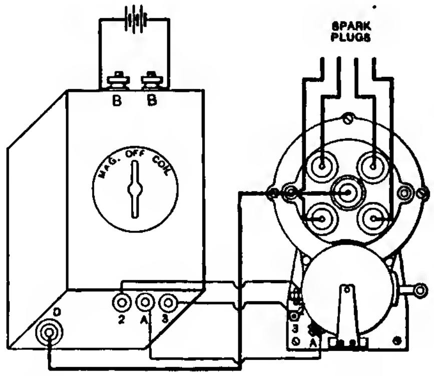


Fig. 8—External view of Splitdorf magneto and distributor. **Fig. 9**—Details of the same. **Fig. 10**—Wiring diagram showing battery used for starting, and terminals connected to coil

When a Body Must Be Purchased—By G. J. M.

This is the second installment of an article dealing with the process of putting a new body on an old automobile for the purpose of bringing the appearence of the automobile up to the most advanced standard, enabling the owner to utilize the chassis until it is worn out in service.

PROGRESS in the solution of this problem will require casual reference to the figures which were utilized in the introductory installment of this article, the idea being to afford the requisite building information.

Style *A* represented a type of runabout body with a clear platform at the rear to accommodate baggage.

Style *B* presented a torpedo stern attachment supplanting the clear platform as shown in Style *A*.

Style *C* depicted a so-called racy type of runabout body with a gasoline tank occupying a position to the rear of the seat, with means for slinging the extra tires in a diagonal position over the rear portion of the platform, clear of the gasoline tank.

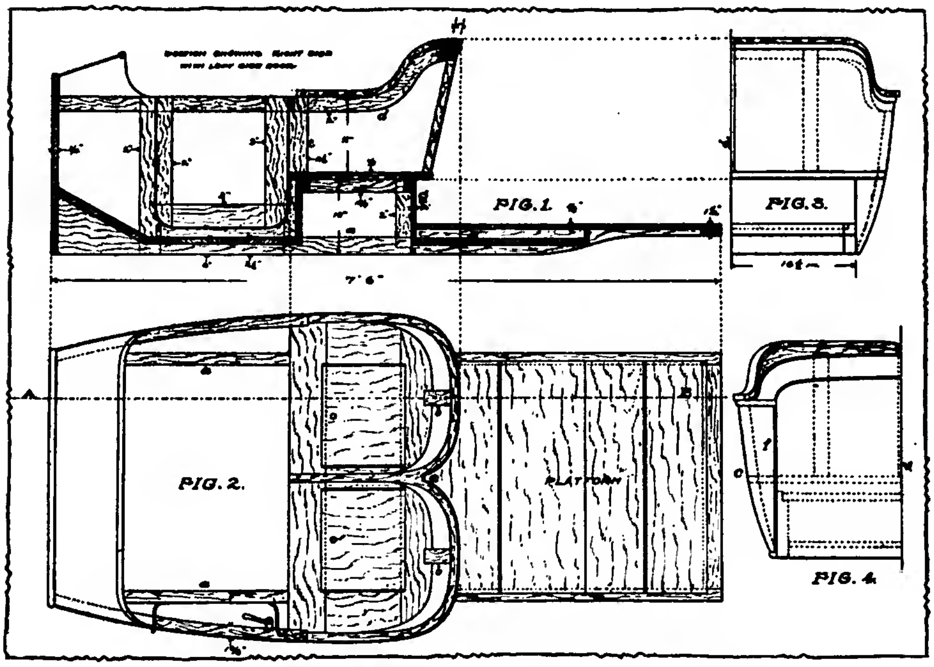
Style *D* showed a toy tonneau with a gunboat characteristic brought about by utilizing doors for all side entrances.

The whole effort has for its scope the idea of following along construction lines which are professional in character, capable of being executed with precision and despatch, enabling the autoist to choose at will, any one of the four styles as above indicated, or to change over from one to the other of the styles when the spirit moves.

In the construction of the Style *A* body, which constitutes the foundation for the whole work, reference may be had to the Figs. 1, 2, 3, and 4, as here given, and it will be understood that Styles *B, C* and *D,* may then be attached at will. Referring to Style *A*, and the figures, with a view to learning how the work is to be done in the construction of the body proper, Figs. 1 and 2 are made of ash in one piece 1 1-2 inches wide by 2 1-4 inches deep at the front, 4 inches deep at the rear of the seat, 8 3-4 inches deep at the toe, and 1 1-2 inches deep at the back end. The next step will be to provide a crossbar, which may be 2 1-2 inches wide, and, as the illustrations depict, it is framed in at a point of vantage.

Both the toe and backboards are made of 3-4-inch ash, but the platform boards, having less responsibility, are thinned down to 5-8-inch ash. Should it be desired to substitute white, or bass wood, for ash, account must be taken of the lack of rigidity of these products to the extent of adding 1-8 of an inch to the thickness. The ironing for the toe and backboards must be done with some care, and it will be a fallacy to undertake to save weight by utilizing flimsy irons which are made by bending strap iron up to the required shape; this product is inferior in its structure, nor will it afford the requisite measure of stiffness, since there will be no body of metal at the junction of the legs of the irons. If the irons are forged up, it will be an easy matter to leave a body of metal at junction points and to taper them away to the ends, so that the distribution of metal will be in accord with the needs, and weight will be saved on a deserving basis. The toe and back boards in this design rest on angle iron supports in stationary relation, using screws for holding. The boards shown directly above are removable, the reason being to afford ample leg room for the tonneau design. All bottom boards, excepting those which are rabbeted into the sills, are removable. The seat framing is of ash 7-8 of an inch thick, the side and cross members are lapped together, and the seat boards are 3-8 of an inch in thickness, made of white wood with cleats on the bottom and finger holes placed near the front edges; the boards rest in rabbets in the frame.

The upper frame *d* is of ash 2 inches deep by 1 inch thick, and is made of several pieces lapped together; it is framed to the posts *c* Fig. 1, and is supported by the posts *bb* Fig. 2, while the center post *e* (of which there are two) is of 7-8-inch white wood and is framed to the post *e*. The curve of the plan, and the shape, considering the side view, are determined on the rail *d*; then, the metal panel, which is of No. 16-gauge aluminum, is rolled to this shape. The top and bottom mouldings or beads are formed in the sheet with a beading former, and stock is left beyond the bead for a distance of 3-4 of an inch in length, which stock is turned at an angle to the sheet, and is used to fasten the panel to the wood frame, a clear idea of which will be gleaned by examining the section at the rear, Fig. 1.



Foundation body work for the four styles of bodies shown

One piece of paneling is used for each seat shape, the fastening at the front being under a half oval solid moulding, or pillow marked *c*. At the pillow *e* the sheets are turned over and nailed, and in this way the joint is covered. In well-equipped body-making establishments, the panels for both of the seats are fashioned in one piece, and at the point *e* the paneling is depressed, but is not cut; this is a cheaper way, and it has the further advantage of affording rigidity, offering the additional inducement of reducing the amount of framing within. Still another method for the sake of economy is employed in large establishments in dealing with the top part. In place of turning the panel above the head of an angle to the sheet, it may be preserved in its original shape in line with the flat of the sheet, and a 3-4 by 3-4 inch bent wood strip is placed on the inside and outside of the metal. These strips are bolted or screwed together, sandwiching the metal between. The advantage to be realized in thus proceeding lies in the fact that the rail *d* is eliminated, and the trimming rail is formed in its absence. Should there be an appearance of flimsiness, which the workman will note, it will be necessary to do a little ironing at this point.

The side framing in front of the seat is symmetrical on both sides with the exception that on the left side, where the rail at the top is cut between the posts to make the door opening, *e*, Fig. 1, which is a section in the vertical plane, to the right side on the line *AB*.

The space between the pillar representing the door opening is shown, and its construction will be readily appreciated. Fig. 2 shows the door correctly placed, and on the right side, the rail at the top is shown. The framing of the door and relating parts are made of 1 3-8-inch wood by the width as given in the drawing; this thickness is used with the idea of affording a certain stability to the door, and the fact must not be overlooked that the thickness changes somewhat, it being 1 1-8 inches at the bottom of the door. The side panels are made of No. 16-gauge aluminum, and are shaped by beating them out on a wooden form under a hammer, so that they fit the winding surface from the pillar *c* to the perpendicular line of the dash *f* (see Fig. 3). The panels so made are fastened under the half oval solid aluminum mouldings at the dash marked pillar *c*, and at the top as well as at the bottom. The moulding should be made to match the rolled moulding of the seat. In the doorway the panel is either bent at an

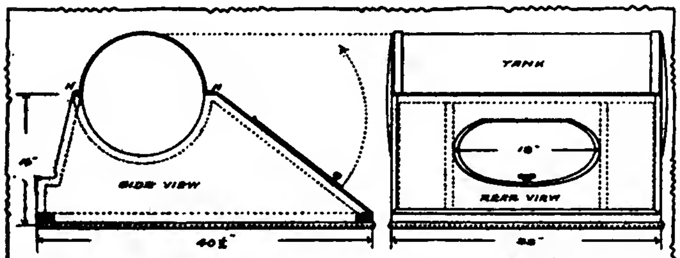


FIG. 8. FIG. 9.

Showing method of proceeding for style C work

angle and secured to the face of the framing, or cut to the edge and fastened on the outside with small wood screws.

The hood is one piece aluminum, using 16-gauge sheets, shaped under the hammer, and, when it is put into place, it is fastened to the dash and to the side frames under the solid moulding. At the rear raised edge, a similar moulding is riveted to the top and to the underside; this forms an oval edge, and it offers the further advantage of rigidity. Body builders take advantage of the presence on the market of the various materials to be had, among which it is believed there is an oval form of moulding, so slotted as to receive the panel.

How the Torpedo Stern Attachment is Made

The torpedo attachment, which is used in the production of the Style *B* body, is illustrated in Figs. 5, 6 and 7, and as Fig. 2 shows, the attachment covers the entire platform back of the seat. This attachment is 12 inches high in the center at the front end; the framing is of wood, the thickness of which is 1-8 of an inch less than the thickness of the wood in the framing of the platform, as shown in Fig. 2 The side and end members are 1 1-2 inches deep by 2 inches wide and frame together. The top metal sheet is a one-piece, No. 16-gauge aluminum product, shaped to the curve, which is substantially a quarter of an ellipse. This shape does not cover the square end of the platfrom at the rear, but the metal is worked out from its normal curvature so that it flattens to the horizontal at a distance 1 1-2 inches up from the base line. This carries the metal over the top of the wooden frame at the corners. The metal is turned over the sides of the framing, and fastened near the lower edge. The effect will be appreciated by an inspection of Figs. 5 and 6 showing the end view, and

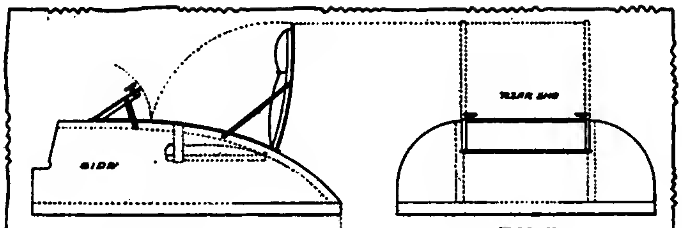

FIG. 5. FIG. 7.

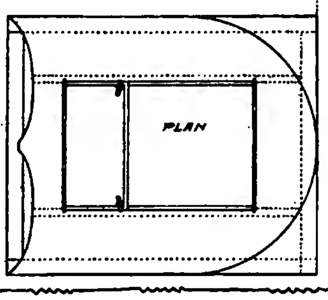

FIG. 6

Plan of the torpedo stern attachment for style B body. It is the idea to either have the body work done so that the attachment can be added at the time or later on. It will also be possible to so design the attachment that it may be detached at will with means for quick removal, when the body becomes a runabout type.

Fig. 7 which presents the 3-4 inch half oval. The next operation is to fasten a T-moulding to the underside of the frame, all around. This moulding will bind the sheet to the frame.

Construction of the Racy Type Attachment

The attachment which is used in the Style *C* body is illustrated in Figs. 8 and 9, and, as shown, this attachment covers the platform completely, and attention is called to the T-moulding which is placed to cover the drawing at the base line, and the metal panel at the front. The height at the front is 16 inches, and the gasoline tank is 15 inches in diameter, with a calculated capacity for 25 gallons of gasoline. In this construction the aluminum panels are No. 16 gauge, the side panels are turned to form an angle which flanges over for 3-4 of an inch. At the front, top, and rear, under the panel flange, an aluminum angle piece, 7-8 by 7-8 by 1-8 inches, is employed, and it is so shaped as to follow the top line of the side panel from back to front, being fastened to the wood frame at either end. Cross members of this same angle iron are shown as *hh* in Fig. 8, and they are riveted to the side angles, using gussets of 1-16 inch thick plate on the underside of the angle pieces, which gussets are all set in the upward direction for 1-16 of an inch, thus bringing the lateral angle pieces flush with the underside of the lateral panels.

Construction of the Toy Tonneau Attachment

The toy tonneau, which is designated as Style *D*, is quite completely illustrated in Figs. 10, 11, 12 and 13. This attachment covers the platform, and the framing of the seat door, and underbody remains as in the preceding example, excepting a difference in length which the drawings give. The seat is made to hold two adults, and the cushion and tonneau dimensions are also given. To this work the body framing and the door posts are framed. The front door post, or lock pillar, is fitted to the curvature of the front seat.

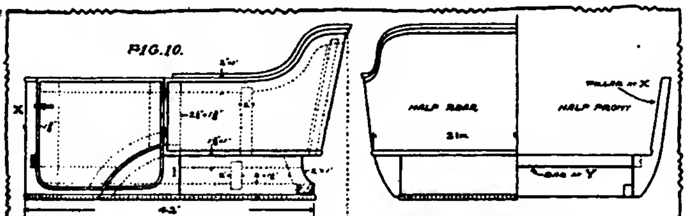

FIG. 12. FIG. 13.

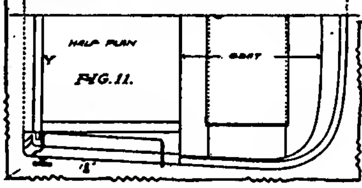

Sections for use in making the Style D toy tonneau. This section is to be used in conjunction with the plan of the foundation body, Figs. 1 and 2, which affords the necessary platform space at the rear.

The Problem of Refinishing Automobile Bodies

By M. C. HILLICK

EACH class of body offers a separate problem. The purchaser when he selects a metal body, for illustration, is inclined to reach the conclusion that he will be entirely free from troubles of every sort. It will be easy to tell him, with the expectation that he will believe it, that a metal body will not check, nor will it, like wood, be more or less destroyed by the force of a blow which would merely put a dent in a metal body. It also looks as if a metal body might be hammered out were it to become damaged. Then, it is a simple thing to point out that wood bodies are much affected by heat, moisture and the other ills of inclement weather.

From the point of view of the repair-man, particularly after the body reaches the paint shop, these nice theories are given but small consideration. It will be found that in hammering out a dent in a steel body it will be almost impossible to bring the sheet of metal back to its original smooth exterior, and it will remain for the finisher to cover up the imperfection by building up with roughstuff and rubbing down with water and artificial rubbing stone. Even this process should include, after the first application of roughstuff, suitable treatment with a hard variety of drying putty. Roughstuff alone will not prove adequate in the process of concealing the dents, and if a bulk of material is required, as it will be if the dents are conspicuous, the drying putty should be used instead.

Before undertaking to refinish a steel body, after it arrives at the repair shop, it is proper practice to carefully inspect every portion of the body, noting the condition of the paint and varnish, observing if there are any fractures, scale, or bruised patches, and having a care to touch up all such imperfections and blemishes, using metal primer and surfacer in equal proportions.

In case a complete refinishing job is to be undertaken, resurfacing with roughstuff comes first, to be followed by touching up with a coat of filler, which should be made of two parts, by weight, of white keg lead to one part, by weight, of roughstuff filler; mix these components to a stiff consistency in equal parts of coach japan and rubbing varnish.

After the application as above, and a lapse of 36 hours, it will then be proper to putty and draw putty all the prominent defects of the surface, stopping off only when there is no longer a foothold for the putty. The completion of this operation should be followed by a period of inactivity for 24 hours, when it will be proper to apply a coat of straight roughstuff which may be either shop mixed or procured ready to use from the manufacturer. From this point on the building up operation may be continued, applying a coat of straight roughstuff daily until the surface is balanced up. This will be the more complete if the process of rubbing, which is alternate with the application of roughstuff, is conscientiously performed. The end will be a uniform level foundation.

After rubbing out, the further processes are quite the same as those which obtain in painting and finishing wood work. In the steel structure the non-porous feature will always have to be coped with, and scale formation is likely to occur. Unless the finishing is very carefully done, the rust and scale problem will be a serious one. In preparing the new steel surface for painting, all rust and scale must be removed. This is best done by means of a sandblast in properly equipped establishments. In refinishing work, the sandblast is also the most effective, but the old burning process is sometimes resorted to, although it is next to impossible to do good work in this way. From the point of view of the owner of an automobile, who, naturally, desires first-rate work at a fair cost, the old burning process is to be shunned, not only on the count that the result will not be very good, but for the excellent additional reason that the cost will be relatively high.

In some establishments not fitted out with sandblast equipment there are solutions to be had which are more or less efficacious in connection with the removal of the old coat, or, if the plates can be removed, the practice which sometimes obtains in car building may be resorted to, in which the plates are immersed in a "pickle" consisting of 20 per cent. solution of oil of vitriol for a time sufficient to accomplish the purpose. After this, the plates are dipped in boiling hot running water, for the purpose of washing away the acid and scale; the plates are then dried, and coated with crude oil, excepting on the inner surfaces, which do not receive final finish, being given a coat of good mineral oil paint.

The plates may then be put back into place, cleaned with benzine, and scrubbed with a wire brush, to be followed with a trustworthy coat of primer. After 48 hours, under proper drying conditions, the surfaces may be re-coated with a mixture of metal primer and surfacer to be followed by a drying period of 48 hours. Puttying and putty glazing is then done, to be followed by two coats of surfacer on two consecutive days. After this, if the surfaces are not in good fettle, additional coats of surfacer must be applied until the desired ground is established. Three days drying will bring the finishing process up to the point where rubbing with artificial pumice stone and water will be in order, and when the groundwork will be sufficiently good to permit of the completion of the undertaking in the customary way.

Aluminum Bodies Are Troublesome

One complaint which is frequently heard in connection with aluminum body finishing takes for its basis the fact that around the edges of the aluminum panels the paint, when made of white lead base, wears off rather too soon. There is no very good explanation for this, but the fact remains that the paint is unseated for some distance back of the edges, although it is well to remember that aluminum oxidizes most readily. In order to get away from trouble of this sort, in so far as it is possible to do so, a reliable mineral primer and surfacer is used in the finishing process, which usually results in a substantial body sufficiently trustworthy to answer the requirement.

Considering wooden bodies, which are usually of white wood or poplar, excepting for the framing, which is of ash, the conditions are much more favorable from the point of view of the finisher. The white wood, or poplar, in the better class of work, is either blocked or canvassed on the inside surfaces, and, next to mahogany, it is the most desirable material for holding the paint and varnish. It is true that white wood and poplar shrink and expand to a considerable extent. This trouble, however, is minimized by chopping down the trees at the proper time of the year and treating the timber in accordance with its characteristics with a view to the elimination of troubles of this sort.

If the best grades of wood are selected for the purpose, thus reducing shrinkage and other troubles to a minimum, an old-fashioned primer may be used with the best result, and the subsequent surfacing materials will lay hold on the wood tenaciously. With the work thus undertaken, the ills of vibration, expansion, and force strains will have but small effect, nor will dampness accumulate sufficiently to change the character of the surface, whereas the work of the painter will be comparatively simple. In the long run, no matter which character of body is sent back to the paint shop to be finished, it will require the exercise of a fair degree of trade skill, the use of excellent materials and rather more time than the average autoist cares to contemplate. The durability of the finish will depend largely upon the skill and the time the artisan takes, but the artistic effect will also involve the use of a wise selection of the color to be applied to the body.

Other varieties of wood are unsuited for good reasons.

American Hubs with Single Ball Bearings

FRENCH technical papers keep a close tab on the doings of American designers, and it is interesting to note that American engineers are in the lead in divers ways, even to the extent, sometimes, of using ideas which are only known to the French school of design through the medium of the technical press. The following translation, which is literal from the well known French technical paper *Omnia*, is made the basis for these remarks:

American Hub with Single Row of Bearing Balls

Thomas J. Fay describes, in the American journal, THE AUTOMOBILE, a hub of which we give herewith a reproduction. We are much inclined to believe that this apparatus has been able to function, but in default of knowing on what vehicles, we are obliged to leave to this author the whole responsibility for its description.

"A very large ball bearing is secured with its inner race member C on the enlarged end portion B of a stationary axle. The spokes E of the wood wheel abut directly with their broadened, wedge-shaped inner ends V against the exterior race member of the ball bearing. Two disks of steel compress the spoke ends by means of bolts U seen in the cut. One of these disks F closes the front of the hub and is provided with a grease cap G. The other forms the brake drum H and the sprocket wheel crown K.

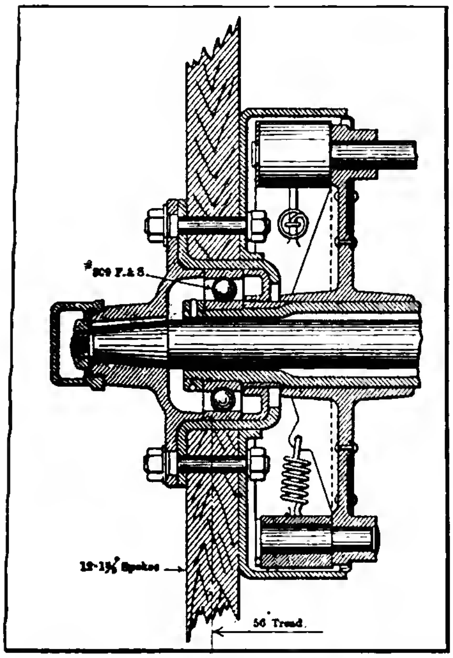

Fig. 2—Abbott-Detroit rear axle construction showing a No. 300 F. & S. annular type ball bearing in the plane of the rear wheel.

"It is undeniable that a single row of balls can easily carry the burden which rests on one wheel of an automobile. But this direc thrust is not the only one to which the hub of a wheel is exposed. The transverse stresses and especially the lateral shocks subject it to ruder tests. It may be a question whether a single row is as well adapted to withstand these forces as a hub formed of two rows placed at a distance apart.

"We do not believe it is impossible; and for this reason we present this original hub to our readers."

In order to show that the single ball-bearing design referred to in the translation from the French, and given here as Fig. 1, is now accepted and in particularly successful practice, it will only be necessary to present one or two samples, and for this occasion reference may be had to Fig. 2 of the Abbott-Detroit rear axle construction, and to Fig. 3 of the Marmon type of rear axle. Referring back to Fig. 2 for the moment, the illustration shows a No. 300, F. & S. type of annular ball bearing, placed in the wheel plane at right angles to the axis of rotation.

Referring to Fig. 3 the Marmon construction, the jack shaft S1 is flanged at its end F1, and a supplementary flange, F2, bolted to the flange of the jack shaft, is faced off and fits against a face on the hub member, H1, of the rear wheel on each side of the car. The hub H1 is bored out to take a single annular ball bearing, B1, and this bearing, while it does all the work, is dead on the center line of the wheel, so that it is in a position to assume all the responsibility. The ball bearing is a sucking fit on the reduced diameter of the bronze sleeve S2, and this sleeve fits over the drawn steel tube T1, which is concentric with the jack shaft.

The ball bearing is held securely in place in the most approved manner by means of a locked threaded shell, S3, and the jack shaft, which is of the semi-floating type, is prevented from floating off by the interference of the petticoat P1 of the hub member H1, acting in conjunction with the flanges F1 and F2, they, in turn, being secured in place by means of the hub flange bolts as shown, and the rivets R1, R2, etc. The hub cap C1 fits over the flange F2, and is held in place by cap nuts N1, N2, N3, etc., and the appearance of the wheel is somewhat unusual, due to the elimination of the conventional hub. The brake drum D1 is fastened to the spokes S3, S4, etc., and the drum, while it is of unusually large diameter, is also very wide, there being room for the two sets of brake shoes S5 and S6, with heat proof facings of a high coefficient of friction.

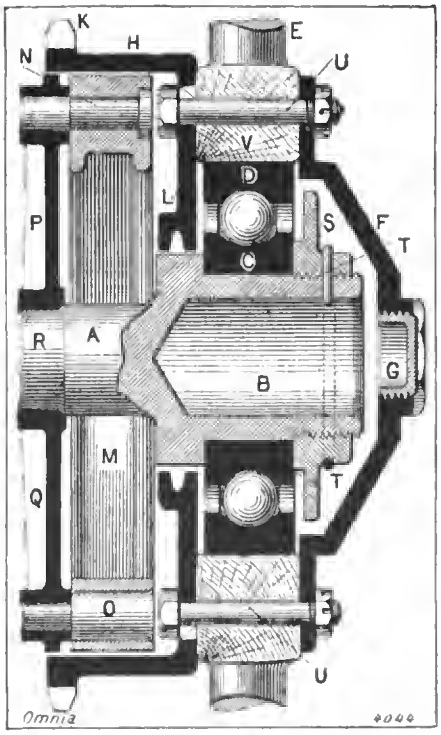

Fig. 1—American hub with a single row of balls. A, stationary axle; B, cavity full of grease; C, inner race; D, outer race; E, wood spokes; F, steel disk; G, hub cap; H, brake drum; K, sprocket chain crown; L, grease retainer; M, brake shoe; N, shaft for the two brake shoes; O, cam for operating brake; PQ, arms secured to the portion R of the axle; S, ball-bearing nut; TT, lock nut for nut S; UU, spoke-fastening bolts; V, inner spoke ends abutting directly against the ball-bearing race D.

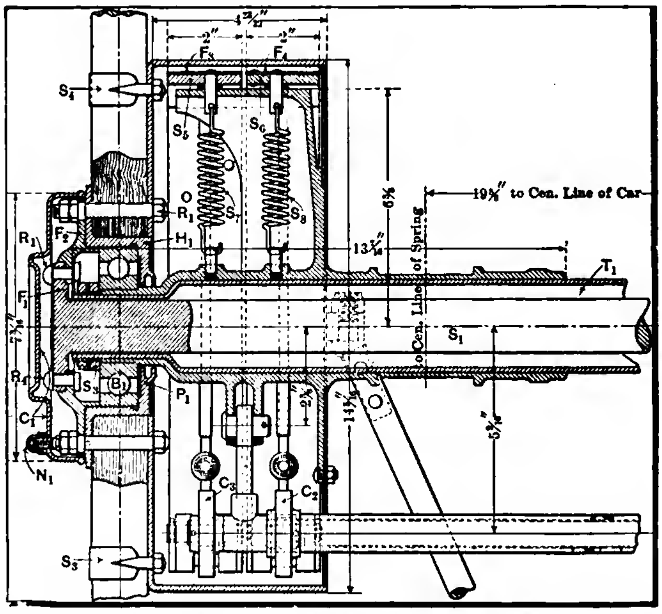

Fig. 3—Marmon type of live rear axle employing a single annular ball bearing in the plane of the wheel

Photographic Insight Into the Mea Magneto

COMPACTNESS in a magneto is second only to an energy spark at the propitious time, not forgetting, however, that the magneto occupies an auxiliary position on one side of the motor, exposed to the silt of the road as it blows in through the interstices of the radiator, part of which passes by and out through slits in the pan, but a goodly portion finds lodgment on the various surfaces under the bonnet, and it has great persistence in that it will creep in through small crevices and mingle with the working parts of the magneto or what not, to the detriment of the fine mechanism concealed within the housing.

In the magneto of the subject, compactness is one of the virtues which will be rendered apparent by glancing at Fig. 1. Moreover, it is shown that the vitals of the apparatus are protected most carefully, and, more, means are afforded for quickly dissembling the magneto, either for the purpose of removing same from its position in the car, or for the lesser intent, should it be desired, to detach a part from the whole. The saddle S1 into which the magneto M1 is placed is bolted down by two holding bolts, one on either side, through lugs L1, and the bottom side of the saddle is planed to a true face, in order that the magneto will securely rest upon a ledge, which may extend out from either half of the crankcase, or upon a shelf, which may be bracketed to the crankcase. The driving gear, if it has a suitable tapered hole in its hub, may be pressed upon the tapered projection of the armature spindle S2, and a nut N1, with a washer W1 behind it, is responsible for the pressure demanded in fetching the gear up against the taper, and holding it in place.

To fully appreciate the niceties of the situation, it will be necessary to turn to Fig. 2, which shows the motor M1 taken out of the saddle S1, and the quick release clamps C1 and C2, which are hinged at H1 and H2, have projections P1 and P2, which engage locking straps S2 and S3, taking advantage of locking cams C3 and C4, which hook over and throw past the center when pressure is applied to the spherical ends of the handles H3 and H4. An adjustment is provided so that if the faces of the cams do not come in the right relation, or if they show wear in time, the distances may be altered to accord with the necessities.

The next step in the procedure is shown in Fig. 3, in which the magneto M1 is partially dissembled, and the cover C1 is taken off, thus exposing the rotor R1, and the distributor shaft S1, also the carbon brushes C2, C3, etc., and the gear G1, which imparts motion to the shaft S1, taking motion from the armature shaft upon which a pinion is placed for the purpose.

Components of the Magneto Shown in Dissemble

The vital parts of the magneto are presented separately in Fig. 4. The armature (rotor) R1, having been removed from the fields F1 and F2 in the housing H1, presents evidences of mechanical refinement, the diameter being made exact by precise machining methods, so that when the armature rotates on its bearings in the end members M1, the air gap distance between the periphery of the rotor and the juxtaposition polar faces is reduced to mere clearance, so that the reluctance of the air gap is minimized, and the flux density of the magnetic field, as measured in lines per unit of area, is the highest obtainable value. The shape of the permanent magnets is shown in Fig. 5. The field piece is formed in dies (hot) from suitable grades of steel, having in view the fact that retentivity is a factor of the first importance. The potential ability of this form of magnet, expressing it in magnetomotive force, is primarily high, due to the careful selection of material and the method of treatment, but the effectiveness of the field is increased materially by virtue of a favorable leakage factor, all of which, in addition to the large polar area in conjunction with

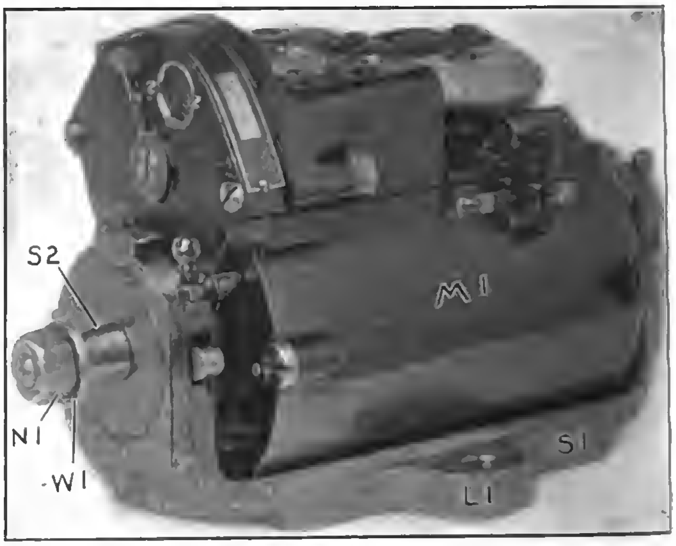

Fig. 1—Mea magneto as it appears ready to go into place on a motor, with means for bolting the same down

a diminished air gap, leads up to the desired result, namely, a high-tension spark possessing a large energy component.

The front plate M1 is held in place by six screws; when they are removed the plate may be taken away also. The armature spindle S1 rotates in ball bearings B1 and B2, at either end, and an examination of the plate M1 will disclose the location L1 for one of the ball bearings, which is duplicated at the other end. The mica-built condenser C1 is concentric with the armature shaft S1, fetches up against the liminæ of the armature R1, sandwiching between it and the insulating spool S2 of the slip-ring S3, thus affording to the condenser a position of advantage, protecting it perfectly from rough usage, and helping materially to maintain compactness of the apparatus as a whole. The breaker B3 on the secondary shaft S4 comprises a suitable spider, and a flat spring carrying the contact point, including a suitable adjustment requiring the use of a screwdriver in the process. The breaker removes together with the armature, and its action in service is promoted by two cams, which are held by screws to the housing of the wheel. Contact is interrupted through the office of a roller

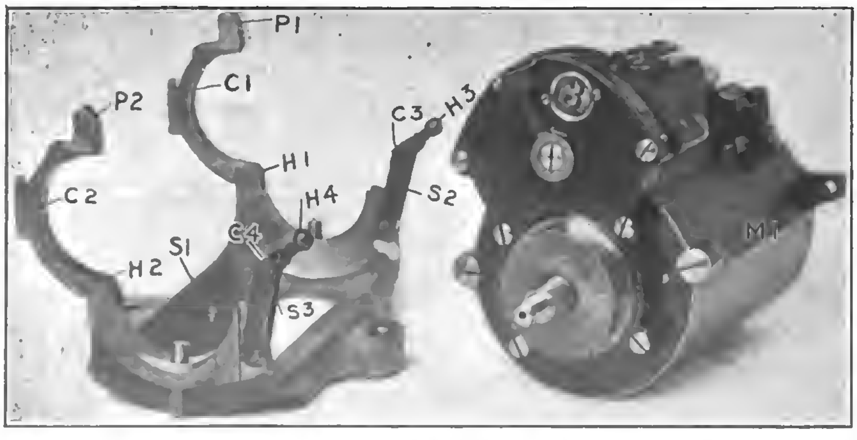

Fig. 2—The magneto after it is separated away from its saddle, showing the details of the saddle

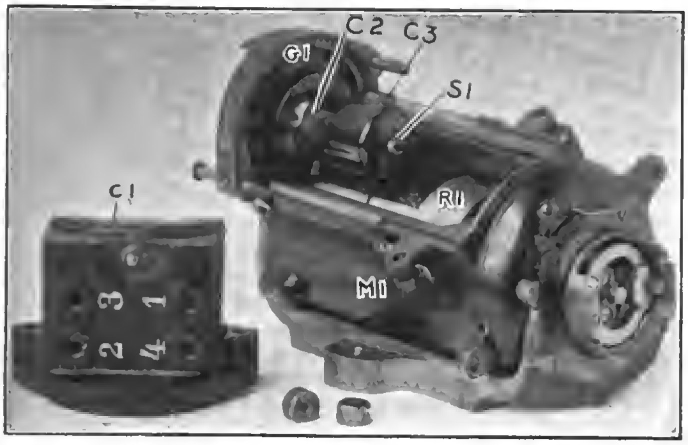

Fig. 3—When the cover is taken off, showing the interior, with a good view of the rotor and other parts

which is timed in view of the requirement. The roller glides on steel discs; they are hard and the motion is easy, so that appreciable wear is deferred.

In the application of the magneto to motors, those with 4 cylinders require that the crankshaft speed of the motor be that of the magneto. For motors with other numbers of cylinders, considering the use of this particular magneto, speed adjustments would have to be made accordingly. The timing levers are attached to suitable lugs, one on either side of the magneto. When the field magnet is run by means of this timing gear a steel disc with two cams, which are held tight by screws to the housing of the field magnet, imparts motion in the required direction to the contact breaker, which is rocked with the field magnets. The breaker will open in all positions between the maximum advance and the maximum retard at the same relative position between armature and field, so that the arc maintains the same intensity. The range of timing is from 60 to 70 degrees, which is quite in excess of the ordinary requirement, but which affords relief from troubles of this character, under the most unusual conditions. There are divers mechanical refinements which take into account the principles which underlie perfected mechanisms, and with a view to merely indicating something of the scientific way in which this magneto was contrived, it is pointed out that the contact breaker opens in the direction of the axis of the armature, hence centrifugal force, which cannot be eliminated, does not act against the good-working qualities of the breaker. The result is that contact is firm, chattering is entirely absent, and the spark produced is entirely free from interfering ways, such as would surely be set up in the electromagnetic couple, should contact be intermittent.

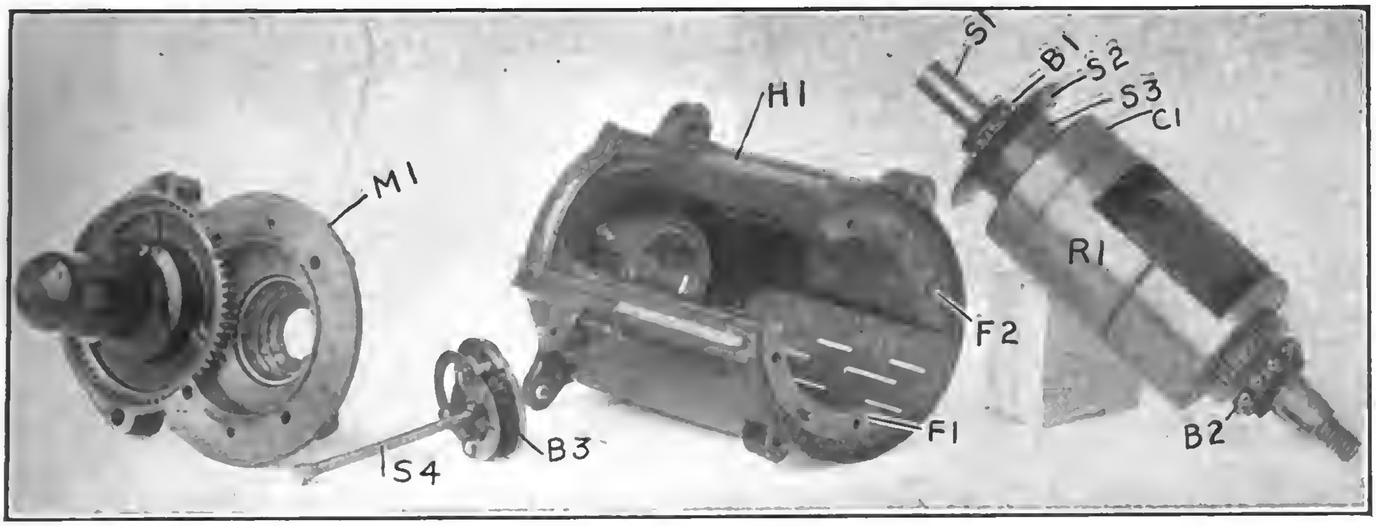

Fig. 4—Components of the magneto after the same is taken apart, presenting the permanent magnets within the housing

Alloys Used As Bearing Metals*

A rather interesting thing about alloys containing sodium is based upon the fact that sodium by oxidation produces a material which will saponify with oil used in bearings.

Investigations have resulted in little progress involving all possible alloys of different materials in different proportions. The recent introduction and placing on the market of a large number of metals, such as calcium, etc., very common in nature, will depress cost, and many of them possess suitable properties for bearing alloys.

Exterior View Automobile Club of Maryland

H M Luzius Sec — T G Hutchison Asst. Sec

BALTIMORE, MD., May 30.—During the nine years that the Automobile Club of Maryland has been in existence it has steadily grown in importance, not alone to the owners of cars in this city and State, but to the public in general. It has ever stood by those who obeyed the laws and has seen that they have not been unjustly treated by the authorities of certain sections, and it has been severe in its stand against reckless drivers. In carrying out this phase of its work, the club has cheerfully co-operated with the authorities in prosecuting speedists.

In recent years the club has taken a more active part in the business and sporting sides of the automobile. It has been active in advocating laws that are fair; it has promoted two of the most successful shows ever held in the South and it has backed a number of contests, such as endurance runs, sealed bonnet contests, hill climbs and the like. At present it is preparing for a hill climb to be held on the Belvedere Hill in June.

In regard to the Swann Motor Vehicle Law, recently passed by the Maryland Legislature, "the club," to use of the words of its counsel, Osborne I. Yellott, "is strictly on the fence." There are certain sections of the law, however, which, it is known, are not at all to the liking of the club members and the organization is having 5,000 copies of the act printed for distribution among the members. The features of the law which the club does not consider to be for the best interests of the motorists will either be underlined or displayed in the margin. The club has a membership of something like 250 which is increasing.

The Automobile Club of Maryland was organized in the days of the infancy of the motor car, at a time when there were hardly more than a dozen autos in the State. The first meeting was held at the residence of the late James E. Hooper, Jan. 28, 1901. Ten were present and became charter members. James E. Hooper was elected president; C. Warner Sttork, secretary; John W. Garrett, vice-president, and Ernest J. Knabe, Jr., treasurer.

On March 14, 1906, the club held its first meeting in the present quarters, 12 West Mount Royal avenue. On Feb. 26, 1906, it was formally incorporated under the laws of Maryland.

By its by-laws, the objects of the club are declared to be "the promotion of a social organization, composed in whole or in part of persons owning automobiles for personal, business or private use: to afford a means of recording the experiences of members and others using motor vehicles; to arrange for pleasure runs and to encourage the development of the auto as a means of pleasure driving and commercial transportation; to co-operate in securing rational legislation and the formation of proper rules and regulations governing the use of motor cars in city and country, and to protect the interests of owners and users against unjust or unreasonable legislation, and maintain the lawful rights and privileges of owners of all forms of automobiles, whenever and wherever such rights and privileges are menaced; and, on the other hand, to bring about, on the part of club members and auto users generally a proper sense of regard for and obedience to all laws and ordinances on the statute books, so long as they are law; to discourage fast and reckless driving and disregard by motorists of the right of others properly using the highways of the State; to promote and encourage in all ways the construction and maintenance of good roads and the improvement of existing highways, and generally to maintain a social club devoted to automobiling and the interests of motorists."

The club's home is one of the handsomest and best equipped buildings of the kind in the country. The stair landing opens into the two main rooms and into a ladies' room. On the Mount Royal avenue front there is a large reception room tastefully furnished, the color scheme being a light green. Glass doors, which form the front of this room, open upon a balcony, from which one has an extensive view. Immediately to the rear of this room, and communicating with it by a large archway, is the meeting room of the club. The color scheme of this room is red and black. In this room all the latest magazines devoted to motoring are to be found. To the rear of this room are the locker room and bathroom.

One regular meeting for the transaction of business is held on the second Tuesday of the month and a regular social meeting on the fourth Tuesday. On other Tuesday evenings there are informal social meetings.

On the fourth Tuesday evening of each month the entertainment takes the form of talks on the construction or operation of automobiles, illustrated reminiscences of tours by members, or, occasionally, musical or literary programs. Now and then a smoker or card party is held, and almost always the house committee provides refreshments more or less Bohemian in character. These social evenings have proved a great feature in the life of the club.

The club stands for good roads, and is ever ready to do anything that, in its opinion, will advance the cause.

The Automobile Club of Maryland has always stood for the abolishing of toll roads throughout the State.

The club during the past year took up actively the matter of erecting road signs leading to Washington and Belair.

Membership in the club is divided into five classes, honorary members, life members, active members, associate members and associate lady members. The honorary membership is limited to 25 and includes, ex officio, the President of the United States, the Governor of Maryland and the Mayor of the City of Baltimore. The members may elect as honorary members any persons distinguished for their political, scientific, industrial or administrative capacities. Life membership is secured by an active member commuting all his subsequent annual dues by the payment at one time of $250. Active membership is limited to 500 members. The entrance fee is $20 and the annual dues $20. By a recent action of the club the entrance fee has been waived for all persons becoming members prior to July 1, 1910. Persons residing more than ten miles from the City Hall, Baltimore, are eligible as associate members. They are entitled to all the privileges of membership except the right to hold office or vote.

Something over a year ago the club found it would be necessary to have a paid official in charge of the clubrooms. Thomas B. Hutchison was named as assistant secretary to perform such duties. He always has on hand in the clubrooms a full set of maps and route books covering Maryland and other sections. He also has printed copies of the laws of other States and blank applications for licenses or registration. In this and divers other ways the club is keeping up the interest all the time.

Officers: C. Howard Millikin, president; Osborne I. Yellott, vice-president and counsel; H. M. Luzius, secretary; Thomas G. Young, treasurer; Thomas B. Hutchison, assistant secretary.

Board of governors: James Stone Reese, Dr. H. M. Rowe, Joseph M. Zamoiski, Joel G. Nassauer, Edward S. Dickey, H. M. Luzius.

Chairmen of committees: James Stone Reese, house committee; Edward S. Dickey, membership; Thomas G. Young, exhibitions and contests; Joseph M. Zamoiski, runs and tours; Osborne I. Yellott, laws and ordinances; Dr. H. M. Rowe, printing and publication.

Coming Events in the Automobiling World

June 20-July 6....Detroit, Mich., Industrial Exposition. Detroit Board of Commerce.

Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.

Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.

Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.

Feb. 13-25, 1911..Chicago Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

June 2...........New York City, N. Y., Trade Association, Orphans' Day Excursion to Coney Island and Return.

June 4...........Philadelphia, Pa., Track Meet of Quaker City Motor Club.

June 4...........Worcester, Mass., Fourth Annual Hill-Climb, Dead Horse Hill.

June 6-14........Atlanta, Ga., Reliability Run to New York City, New York Herald and Atlanta Journal.

June 7...........New Haven, Conn., Hill-Climb up Shingle Hill, Yale University Automobile Club.

June 10-11........Fort Erie, Ont., Track, Race Meet under management of Buffalo interests.

June 11..........Portland, Ore., Road Races of Portland A. C.

June 11..........Wilkes-Barre, Pa., Annual Hill-Climb up Giants' Despair, Wilkes-Barre Automobile Club.

June 14-15.......New York, Reliability Run of Motor Contest Association.

June 14-30........Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, Through the Southwest.

June 16-22.......Albany Automobile Club, Albany, N. Y., Sixth Annual Tour to Atlantic City and Return.

June 18..........Ossining, N. Y., Hill Climb of Upper Westchester Automobile Club.

June 18..........Baltimore Hill-Climb of Automobile Club of Maryland.

June 25..........Port Jefferson, Long Island, N. Y., Hill-Climbing Contest, Automobile Club of Port Jefferson.

July 1-10........ Los Angeles, Cal., Road Carnival of Licensed Dealers.

July 2-4..........Los Angeles, Cal., Speedway Meet.

July 4............Auburn, N. Y., Hill Climb of Automobile Club of Auburn.

July 4............Cheyenne, Wyo., Track Meet of Cheyenne Motor Club.

July 4............Dallas, Tex., Track Meet of Dallas A. C.

July 4............Indianapolis, Ind., Cobe Trophy Race. Held on Speedway Track, Chicago Automobile Club.

July 4............St. Paul, Track Meet of Minnesota State Automobile Association.

July 4............Wildwood, N. J., Track Meet of Motor Club of Wildwood.

July 4............Wildwood, N. J., North Wildwood Automobile Club, Race Meet and Club Run to Track.

July 11..........Plainfield, N. J., Hill Climb of Plainfield Automobile Club.

July, Middle of...Richfield Springs, N. Y., Hill Climb.

July, Middle of...Grand Rapids, Mich., Road Race of Grand Rapids Automobile Club.

July 18-22.......Milwaukee, Reliability Run, Wisconsin State Automobile Association.

July 18-23.......Milwaukee, Wis., Tour of Wisconsin State Automobile Association for Milwaukee Sentinel Trophy.

July 30..........Wildwood, Pa., North Wildwood Automobile Club, Race Meet and Club Run to Track.

Aug. 1...........Minneapolis, Minn., Reliability Run of Minneapolis Automobile Club.

Aug. 3-5.........Galveston, Tex., Beach Races, Galveston Automobile Club.

Aug. 15..........Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.

Aug. 15..........Start of Munsey Tour.

Aug. 17..........Cheyenne, Wyo., Track Meet.

Sept. 2-5........Indianapolis, Ind., Speedway Meet.

Sept. 3...........Wildwood, N. J., Reliability Run of North Wildwood Automobile Club.

Sept. 5...........Wildwood, N. J., Track Meet.

Sept. 5...........Cheyenne, Wyo., Track Meet.

Sept. 5...........Wildwood, N. J., Speedway, Labor Day Race Meet of North Wildwood Automobile Club.

Sept. 17..........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.

Sept.............Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.

Oct. 1...........Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.

Oct. 8............Philadelphia, Fairmount Park Race, Quaker City Motor Club.

Oct. 15...........Long Island Motor Parkway, Grand Prize, Automobile Club of America.

Foreign Shows and Races

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.

May 28-June 9...St. Petersburg, Russia, Automobile Exhibition.

June 2-8........Prince Henry (German) Touring Competition.

June 13-18........Scotland, Scottish Reliability Trials.

June 20..........French Voiturette Race.

June 21..........French Stock-Car Race.

June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.

June 27..........Speed Trials at Kiev, Russia.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

REPETITION of a statement, presenting it as the outline of fact, even though it may not be, gives to it the tone of truth without the substance. How it is possible to be hypnotized into believing that a thing is so, despite the fallacy it conceals, is no more fittingly illustrated than when the question of starting on the spark is given the investigation it deserves, in view of a wide belief in the efficacy of the plan. Scores of correspondents, generously differing with a statement which was made in "Letters Interesting, Answered and Discussed," were all in complete accord, each offering apparently conclusive evidence of the alleged fact that starting on the spark should be regarded as a normal expectation, even though the combustion chamber in each cylinder of a motor is relieved of compression before the effort is made.

There are times when certain types of motors, notably those with four or more cylinders, working four-cycle, will permit of starting on the spark, as it is called, but the best way to ascertain the proper range of this idea lies in giving it a trial under practical conditions, involving enough of the various makes of automobiles to permit of striking an average. In view of the wide interest which seems to be taken in this phase of the autoing situation, the Editor decided to put the idea to test, and a garage was selected which permitted of handling upwards of 100 automobiles, most of which represented the higher-priced products, but, taking it on the whole, they represented a sufficient range of thoroughly good automobiles to make the demonstration thoroughgoing. The result of the test may be stated briefly: Sixty-five automobiles were tried by the chauffeurs who run them, and strange to relate, in view of a persistent tradition, not one of them offered to support the contention that "starting on the spark" is a normal expectation.

It will be fair to state that the attempt was made in the morning as each chauffeur came into the garage for the purpose of taking his car out. Each was accosted and requested to start his car on the spark, rather than to use the starting crank. It may be interesting to observe that not one of them seemed to be oversanguine, but they nevertheless agreed to make the attempt, which proved to be futile in each case. The conditions were normal, nor was the weather cold. A variety of cars were represented.

✦ ✦ ✦

IGNITION methods are being refined up to the level of the most fitting requirement, and in step with the progress which is being made in the other departments of the industry, just now the double spark idea is being tried out in racing automobiles abroad, for the most part, but in America to some extent. The method of procedure involves the use of a magneto unit which is provided with a double armature, and a distributor which is so contrived that the two sparks are delivered simultaneously. Two spark plugs are used in each cylinder, they being placed at diametrically opposite points, so that the mixture is ignited from two points of vantage, thus hastening the flaming of the mixture so that there will be less, if any, combustion going on during the period of the power stroke. This plan seems to be good, in that it increases the weight and thermal efficiency of the motor; it also affords a good measure of safety, and it reduces the number of accessory units. Since the double magneto will still furnish one spark, if the part of it which furnishes the other is out of order, it offers a means of dispensing with the customary auxiliary ignition system.

✦ ✦ ✦

MOST conspicuous among the motors which have won renown in aviation work are those in which the cylinders revolve in a vertical plane, the motion dispensing with the flywheel and its weight, with water-cooling and with the fan. Air-cooling generally has, of course, received the benefit of renewed investigation in France, where it had been once somewhat lightly discarded. The same is true of the two-cycle principle, and of the double-opposed horizontal motor, and, having let themselves loose, the French designers have taken the step in full and have lately produced a two-cycle, double-opposed horizontal, air-cooled motor which appears to do excellent work. At the same time, the five, seven and nine-cylinder motor with the cylinders placed radially, but not revolving, is becoming popular, and others have turned their attention to the further refinement of the copper-jacketed racing motor and, by thinning its walls and lengthening its stroke, have produced an engine which seems to be less thirsty for an excess of lubricating oil than its progenitor in the automobile racing field. It is hardly conceivable that out of so much activity, most of it directed by the most skilful motor designers in the old world, there should not accrue distinct gains for all motor-employing industries and all motor users, particularly automobilists.

Curtiss Flies From Albany to New York

GLENN HAMMOND CURTISS flew from Albany, N. Y., to New York City Sunday morning, making the trip of 137 miles in 2 hours and 32 minutes' flying time, or at a rate of 1 mile in 1 1-8 minutes, on an average for the flight. Mr. Curtiss in his biplane then continued the trip from the city limits to Governor's Island, completing the exhibition exactly at noon.

En route from Albany he made two stops, the first at Poughkeepsie, where he stayed for an hour, and the other at Inwood Park, which is within the limits of the metropolis, where he remained for 1 hour and 7 minutes.

The start was made at 7:03 Sunday morning under most favorable conditions, and the biplane almost at once rose to an elevation of 1,000 feet over the Hudson River and shot southward at a high rate of speed. At Poughkeepsie a perfect landing was made, 75 miles from the start. Here the supply of gasoline and oil was replenished and 1 hour later the southward course was resumed. The prize trial was concluded at Inwood Park, where further supplies of gasoline and oil were taken on board and then Curtiss gave a complimentary flight for the benefit of New York's millions by traversing the North River clear to the Battery and Governor's Island. The exact elapsed time from Albany to New York was 5 hours, lacking 3 minutes.

On the entire trip, Curtiss used seven gallons of gasoline and about two of lubricating oil.

The trip was undertaken in a successful effort to win a prize of $10,000 offered by the New York *World*. This was paid to the aviator within 3 hours after he landed. Incidentally he wins the Scientific American cup, an emblem offered to the American aviator who made the longest flights. Curtiss had already achieved two flights that exceeded those of his rivals, and the Albany-New York event clinched his ownership of the trophy.

The aviator carried a letter from the mayor of Albany to Mayor William J. Gaynor, bearing good wishes and felicitations. A special train left Albany at the same time as the aeroplane and had much difficulty in remaining in sight of the airship, so swift was the pace set.

Curtiss was elaborately received, and ever since his flight has been the center of attention. He was the guest of honor Tuesday night at a banquet given by the *World* and has been visited by many of the business, social and political leaders of this section.

In forecasting the future of the airship Curtiss told Mayor Gaynor that he believed it would be developed into fishlike form and would attain a speed of 100 miles an hour without noise, supplanting all military and naval force.

The announcement of a $30,000 prize for a flight from New York to St. Louis has been made on behalf of the New York *World* and the St. Louis *Post-Dispatch*. During the banquet tendered the aviator, Mayor Gaynor arose and said that he had been commissioned by the two newspapers to make the offer. The terms under which the award will be given have not yet been framed, but will be in the immediate future.

Oswald Motor Company Expands

SOUTH BEND, IND., May 30—The Oswald Motor Company of Goshen, Ind., has taken steps to increase the capacity of its plant. Two additions will be erected at once, one being 165 by 65 feet, two stories high; the other will be two stories high, 132 by 45 feet. Both additions will be constructed from cement blocks and from $10,000 to $15,000 will be spent for equipment and the present number of employees will be doubled. The company announces that its entire output for 1910 and 1911 has been sold.

The Greater Laporte Good Roads Association has been launched at Laporte, Ind., for the purpose of building good roads out from that city. Officers were elected and committees were appointed to look after the different phases of the work.

No 24-Hour Race for Atlanta

ATLANTA, GA., May 30.—The Atlanta Speedway Association has announced with great positiveness that it will not attempt a 24-hour race this year. Assistant Secretary "Bill" Nye went to the Brighton Beach track to see if there appeared a good chance of making a go of all-day racing at the Georgia capital. His verdict was "no." So work is going on for a local meet to be held about Midsummer. This event will be made up chiefly of amateur races, with a few contests for the local professionals. If properly worked up this event should be one of much local importance.

The local Speedway Association is working hard to get its Fall dates changed to October 27, 28 and 29 and has petitioned the A. A. A. for those dates.

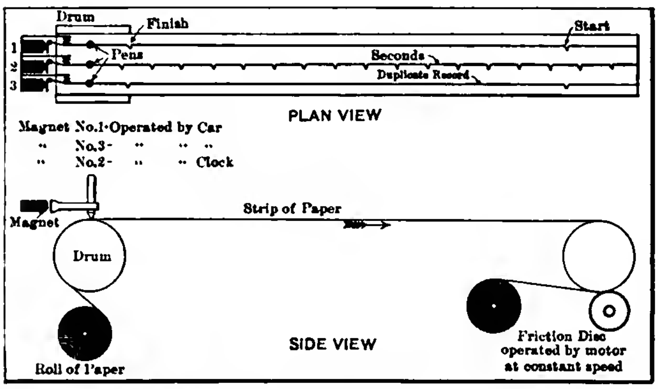
Dead Horse Hill Will Have New Timing Equipment

WORCESTER, MASS., May 30—For the first time in the history of the Dead Horse Hill climb and possibly for the first time in any similar contest, electrical timing of the cars will be made, and the new apparatus will be remarkable for its reliability and accuracy. The apparatus to be adapted for the June 4 contest is from instruments belonging to the department of mechanical engineering of the Worcester Polytechnic Institute, and will be in full charge of Prof. David I. Gallup, who will be assisted by John C. Harvey and C. D. Knights, students of "Tech."

Prof. Gallup's apparatus consists of a roll of paper on a drum driven at constant speed by a small motor and on which are indicated seconds intervals through an electrically connected clock and pendulum, and the speed of the paper is such that a second interval may be made equal in length to 4 in., which will be sufficient to determine time to one-hundredth of a second.

The instant a car passes over the line (either at the start or finish) an electric circuit will be opened by a specially devised snap switch, and this will be indicated on the moving tapes, each of which will be marked with the make of the car and its number, event number and driver, in order that the record may be kept on file.

In order to reduce to a minimum any chances of error, the system will be installed in duplicate, and connections will also be made so that the instant a car crosses the starting line and that of the finish, a series of single-blow gongs, placed at intervals up the steep course, will be rung, so that all the spectators along the course will be enabled to note the time of the car's starting and also of its crossing the finish line, at the top of the hill. The system, so far as it has been tested, indicates a mastery of a difficult situation.



Recording mechanism used in timing cars at Worcester hill climb.

Montreal to Have Aviation Week

MONTREAL, May 30—Official announcement has been made that a world's flying meet will be held at Montreal June 28 to July 4. This will be known as "Aviation Week". The meet is to be held under the auspices of the Automobile and Aero Club of Canada, and will bring together aviators from all parts of the globe, including England, France, Germany and United States.

In addition to aeroplanes, there will be balloon races of the spherical and dirigible type, parachute drops and bomb acts. Many American pilots will take part in the lighter-than-air types of aerial craft exhibitions.

120 Taxis for Orphans' Day Run

Taxicabs to the number of 105 for Orphans' Automobile Day were donated by the New York Motor Cab Owners' Association. If twenty-five more private cars are offered, no child will be left behind this year.

The constituent firms of the association who will donate the taxicabs are the New York Cab and Auto Company, New York Taxicab Company, Universal Taximeter Cab Company, Mason Seamon Transportation Company, Taxi Service Company, Renault Taxicab Company, Kayton Taxicab Company, New York Transportation Company, Haverty Taxicab Company and the Toggart Taxicab Company.

The Connecticut Cab Company already donated fifteen yellow taxicabs and these added to the 105 will make 120 taxicabs in line. This worthy effort on the part of the good citizens is gaining ground from year to year.

Walter J. Gould Meets Death on the Road

The many friends of Walter J. Gould, late assistant superintendent of the Grout Auto Manufacturing Company, of Orange, Mass., will learn with regret that he met his death May 24. The machine was being driven on the State Highway in the town of Merrimack, which is about two miles north of the village of Reed's Ferry. The chauffeur failed to observe a sharp curve ahead and the automobile was going too fast to make it; the car turned over, landing the five occupants on the hard ground with fatal results to Mr. Gould.

The other passengers were more or less severely injured, notably Charles M. Hecker and William Castner. Medical Examiner George M. Davis, of Manchester, was summoned to the scene, and worked over the injured men, but could do nothing for Mr. Gould. Mr. Gould was married and leaves a widow and son.

Busy Week in the Michigan Automobile Center

DETROIT, May 30—Following the epochal news of last week, when the United States Motor Company announced the establishing here of a division headquarters, there has been something going on all of the time.

Five new factories were announced during the week, two for Detroit, one for Wyandotte near by, one for Pontiac and the last for Mt. Clemens, about 30 miles northwest. Of the two Detroit plants, one, the Dayton Airless Tire Company, is moving here with 300 to 500 employees from Dayton, O. Col. J. C. Hooven, of Hamilton, O., is largely interested, while the following Detroiters are officers or directors: Frank C. Van Dyke, president of the Van Dyke Motor Car Company; George C. Clark, its treasurer; S. Olin Johnson, of the Penberthy Injector Company; Wilbur Brotherton, manager of the Jerome B. Rice Seed Company.

The purchase of a fifteen-acre tract of land at River Rouge, within the city limits, is said to mean that that part of the city will soon have a large plant. The automobile concern in question has a car in the city demonstrating its worth, and promises to employ some 100 men at the start, bringing most of them from their present location in Ohio.

The purchase of a seven-acre tract of land at the corner of South Saginaw street and the town line road, Pontiac, by R. F. Monroe, of the Monroe Body Company, is said to mean one more big factory for that town, although Mr. Monroe, when seen, refused to either deny or affirm the report.

At the same pushing town, the General Motors band has been organized, and Mayor Monroe was elected president. Twenty-four men came out to the first rehearsal. The object of the band is to boost Pontiac and incidentally have a good time.

Detroit is vitally interested in the question of exports to Canada, for many of the automobile plants here have Canadian branches, and if the trade would warrant it, many more would establish factories there. That this would be a wise move is shown by the Government's report for the first ten months of the fiscal year, in which the increase over the corresponding period of the previous year was shown to be from $1,123,723 to $3,055,456, a neat little raise of $1,931,733, or 172 per cent.

Many factories are already taking an active part in the plans for the Industrial Exposition, which begins June 20 and lasts until July 6. The Regal Company has invited every Regal agent in the United States to attend the exposition as its guest. The following dealers visited the Chalmers factory recently and made arrangements for their 1911 allotments: Charles S. Snyder, Snyder Automobile Company, York, Pa.; J. W. Gillis, Rochester, N. Y.; L. W. Hodgins, Columbia Garage, Spokane, Wash., and S. S. Primm, Park Automobile Company, St. Louis. On the same day, William T. Taylor, of the Taylor Motor Distributing Company, Philadelphia, visited the Warren plant, and signed up for 1,000 Warren-Detroit "30's" for 1911 delivery.

President John Anhut, of the Anhut Motor Car Company, returned from Toledo last Friday with contracts for 410 Anhut sixes, and options for 440 more. This contract was made with the Ohio Motor Sales Company, of Toledo, distributors for this make of car in Southern Ohio.

The supply of good help is much below the demand, as evidenced in the advertising columns. Just at present there seems to be an unusual demand for draftsmen to work on 1911 models. The Hupp concern is seeking assemblers and engine men; the Packard company body builders and painters; the Metzger Motor Car Company lathe hands, tool designers, other machinists and carpenters; the J. C. Wilson Body Company watchmen, body builders, sheet metal workers and painters; at the Brush Runabout plant, carpenters are in demand; as are machinists and assemblers at the E-M-F plant No. 3; also body builders at the Yeomans Body Company. More than this, several Cleveland firms are endeavoring to reduce the available supply of men by seeking help here to go to Cleveland.

All work and no play make Jack a dull boy, so the workmen are stimulated in their desires to have a good time. In the baseball line, much has been done to further a healthy rivalry between the various automobile factories, this resulting in the formation of two leagues, one being known as the Automobile League, and comprising as members the following: E-M-F, Chalmers, Anhut and Grabowsky Power Wagon Companies. In this league, L. Robert Lilly is president, Frank J. Donahue, secretary, and Thomas F. Manning treasurer. A. G. Spaulding & Bros. have denoted a handsome trophy to the winners of the pennant. The other is a six club league, the members being: Brush Runabout, K-R-I-T, Detroit Lubricator, Dodge Bros., Detroit Radiator and Jos. N. Smith Companies. The league is called the Auto Parts League, and has as its initial officers: S. E. Allo, Brush Company, president; W. R. Webb, K-R-I-T Company, vice-president. Two parks have been secured and another will be before the opening of the season on June 4. On this and each succeeding Saturday, three games are scheduled right through to the first of October, when the League will, in all probability, transfer its energies to football.

Baltimore Club Plans Big Climb

BALTIMORE, MD., May 31—Secretary H. M. Luzius of the Automobile Club of Maryland stated that there would be at least 50 cars in the Baltimore hill-climb on the Belvidere Hill, June 18. A new ruling of the committee will compel each car to carry a full load of passengers, cemmensurate with its capacity.

The timing will be by means of an electric device which will split seconds. Joel G. Nassauer is chairman of the climb committee, the other members being H. M. Luzius and Frank H. Hack, Jr.

June 15 has been selected as the date for Orphans' Day in this city. This event will not be under the auspices of the Automobile Club of Maryland as heretofore, but will be given for the benefit of the little ones by the Baltimore *News*. This paper has taken up the cause of the orphans and already its appeal to motor car owners of the city has met success. Many of them have expressed their willingness and pleasure of loaning their cars for such a purpose. The boys and girls will be taken for a jaunt through the city and suburbs and back to their homes after having a big dinner.

Automobile Notes from Louisville

LOUISVILLE, May 30—More than 200 Kentucky motorists attended the races at the Indianapolis Motor Speedway. Half of this number left Louisville Sunday morning and arrived in Indianapolis the same afternoon. The trip was made in fifty cars under the auspices of the Louisville Automobile Dealers' Association. Carl Reimers was the pacemaker on the 126-mile trip.

Roy C. Packard, an enthusiastic motorist of Pensacola, Fla., arrived in Louisville May 27 after a 1,000-mile trip.

If the plans of members of the Louisville Automobile Club are carried out, Louisville will have a magnificent floral parade on July 4. In order to stimulate interest in the event the following prizes have been offered: First prize, $100; second prize, $60; third prize, $40. No car can enter the parade unless properly decorated.

The route committee of the Louisville Automobile Club have mapped out the second annual reliability and economy contest. The run this year will be through the western section of the State and there will be three days of travel. The exact date of the contest has not been fixed.

Giant's Despair Climb Attractive

Wilkes-Barre, Pa., May 30—Entry blanks for the fifth annual hill-climbing contest up the Giant's Despair course under the auspices of the Wilkes-Barre Automobile Club, which takes place on Saturday, June 11, were sent out to-day. There are to be eleven events and the prizes offered aggregate in value $2,520. The first five events are for gasoline cars varying in size and power and having a piston displacement of from 161 to 230 cubic inches to cars with a piston displacement of from 601 to 750 cubic inches.

The sixth event will be for the $1,000 Hollenback trophy, which has been won once by the Knox Automobile Company and once by the Corbin Motor Company. It has to be won three times by one entrant to become his permanent property. This event is for cars costing between $2,000 and $3,000.

The seventh event is a free-for-all gasoline cars, with a first prize of $250, a second of $100 and a third of $25.

The winner of this event will not be allowed to take part in the invitation or consolation race for all cars, with a first prize of $150 and a second of $50.

List closes at midnight, June 6. The course is now being prepared and is already in fine condition. It is to be patrolled on the day of the race by troopers of the State constabulary and special officers, and will be open for practice for the contestants on the Wednesday, Thursday and Friday before the race. The course is 6,000 feet long, and has a rise of 700 feet with one sharp elbow and the "S" turn and the grades are from 10 to 22 per cent.

The general contest committee includes J. H. Perkins, Guy W. Moore, P. S. Ridsdale, George W. Lewis and T. A. Wright.

Roads for Central New York Relay Run

Albany, N. Y., June 1—Chairman S. Percy Hooker, of the State Highway Commission, writes to the automobile clubs of Central New York, in substance:

"It is the purpose of the State Highway Commission not alone to construct State and county highways, but to see that the town highways are improved in accordance with the amount of traffic they are called upon to carry. Much was accomplished during the year 1909, and still better results are looked for during the present year. The improvement of all the roads in the State cannot fail to increase the values of farm lands to a marked degree.

"I have noticed in certain newspaper articles that special efforts were being made to improve the highways over which the projected relay run will be made, resulting in the neglect of other roads. This is an incorrect impression, and may have arisen from the fact that on the roads which are the cause of these comments, the improvement has been very marked as compared to any other era, and it might naturally be thought that efforts were being concentrated along certain main thoroughfares. Investigation will disclose that such is not the case. In the agreements for the expenditure of highway moneys in every town of the State, the rule was rigidly insisted upon by this department that each mile of road in each town of the State should receive the attention which its importance demands. The purpose of the Bureau of Town Highways is to see that all the town roads of the State receive due attention, and I believe that the roads in general have greatly improved.

"I should regret very much to have the impression go abroad that these roads were especially prepared for this relay run."

(Signed) S. Percy Hooker, Chairman.

Nashville to Have Auto Club

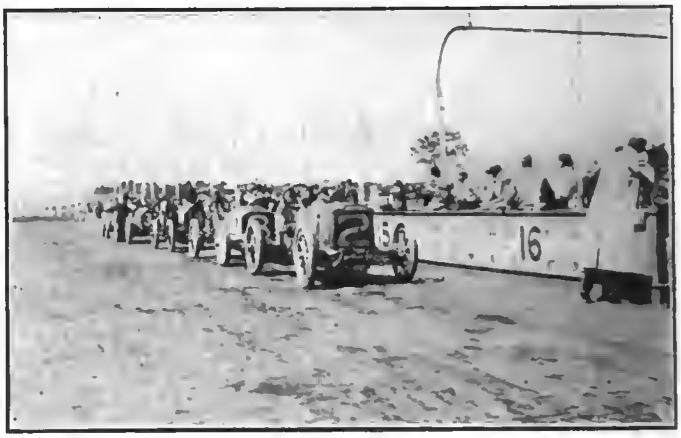
Nashville, Tenn., May 30—Nashville at last has a full-fledged automobile club after several ineffectual attempts. The fact that the Glidden Tour is to pass through here has awakened the auto spirit and brought about the formation of the club.

Records Fall at Indianapolis

(Continued from

Indianapolis, Ind., May 27—The Hoosiers showed they were eager for another taste of speedway racing after a winter spent in discussing the pros and cons of track surfacing, wondering whether or not the brick pavement would come up to expectations in a speed way and whether or not Indianapolis would regain the stock-car marks captured by Atlanta last fall. The results of the afternoon effectually answered these questions in the affirmative. No free-for-all marks were shattered, but in nearly every one of the class events run Indianapolis had the better of the argument with Atlanta.

The new brick surfacing proved fast, and demonstrated that it is not as rough on tires as expected, especially with the smaller cars. The shaving given the bricks by the Overland



Ready for Speed Trials at Indianapolis Speedway

testers proved most beneficial and not a single complaint was heard as to the track.

Wilcox, National, Winning 10-Mile Handicap

The 6,000 people who were in the stands came early and stayed late, and they enjoyed every bit of the racing. While the action of Referee Pardington in ruling out several cars on the ground that they did not come up to the stock car definition shot holes in the program, so to speak, the people did not complain even though these enforced scratches left but three Nationals as starters in one of the races.

Of course, the main event of the afternoon was the 100-mile race for the Prest-O-Lite trophy, won last year by the Buick, but which did not have a chance to defend its title because of Referee Pardington's ruling, which made Chevrolet and Burman sit on the side lines. The Westcott and two of the three Jacksons also came under the referee's ban. This left in the

—W. & S. Cup to Marmon

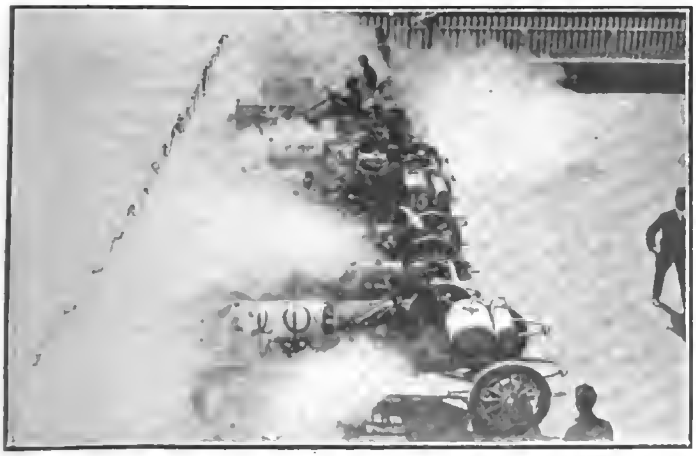
Page 991.)

field Fox in the Pope-Hartford, Aitken, Kincaid and Merz in Nationals, Lynch in a Jackson and Harroun and Dawson in Marmons. Aitken set the pace at the start, but he had plenty of competition, for the two Marmons dogged his heels continually while he was trying to shake the field. This trio formed the first group, while in grim pursuit and some little bit back were Kincaid and Merz.

The first trouble came in the sixth lap when Fox, in the Pope-Hartford, was put out of the running by a broken steering knuckle, which caused him to run off the track on the inside and break a wheel. Neither driver nor mechanic was hurt and the race proceeded. Shortly after this the Nationals began to have tire troubles, so that at the end of 20 miles Dawson's Marmon

Start of 200-Mile Event; Line Up in Front of the Judges

had assumed the lead. At this stage Kincaid, the ultimate winner, was next to last, the Jackson being the trailer. At 30 miles



Start of 10-Mile Stock Chassis Race

Harroun was the pacemaker, closely pursued by Dawson and Merz, while Kincaid was absolutely last. Harroun later lost three laps with valve-tappet trouble, and at 40 miles his team mate, Dawson, was making the running, the Nationals still fighting tire troubles. Dawson continued to pick up the odd seconds and at 60 miles he was 2 minutes 18 seconds to the good, with Merz the runner-up.

When Dawson was two laps ahead he had to stop at the pits for the first time. This was in the thirty-sixth round and an examination disclosed the same trouble experienced by Harroun—valve tappets. It sounded the death knell to the Marmons'

(Continued on page 1024.)

Motor News from Ohio Capital

Columbus, O., May 30—Development in the rubber and tire factories of the Rubber City are coming thick and fast, and during the past week a number of additions and extensions were planned in the tire factories. Hardly a day passes but what a building of some description is planned.

The Firestone Tire and Rubber Company is planning extensive additions to its plant. Last week a contract was let to George W. Carmichael & Company for a new $500,000 plant. The building is to be completed by the beginning of 1911.

The Star Rubber Company is completing a large addition which will double the capacity of the plant. Two buildings were recently added to the plant, each of which is 100 by 50 feet, and other additions have been authorized.

The O'Neil Tire & Protector Company expects to move from its present location in a few weeks to the upper floors of the Adamson Machine Company's plant on West Exchange street.

The B. F. Goodrich Company is making extensive alterations in its plant since completing a number of large additions, and the Diamond Tire and Rubber Company is also making extensive changes. The Goodyear Tire & Rubber Company is not only erecting additions in Akron, but has also built a factory in Canada, the first American firm to build on the other side of the border.

Arrangements are being made for the annual Orphans' Day under the auspices of the Columbus Automobile Club, early in June.

Miss Blanche Stewart Scott, Vassar graduate, of Rochester, N. Y., and Miss May Lyman Phillips, of Boston, who are making the trip from New York to San Francisco in an Overland car, passed through Columbus recently on their way to Indianapolis, where they witnessed the automobile races.

The Anderson Automobile Company, of London, Ohio, was incorporated with a capital of $1,500 to operate a garage by H. Anderson, C. L. Hutchinson, J. L. Graham, George M. Hickle, I. J. Collins and John H. Keller.

The Canton Motor Car Company, of Canton, Ohio, was incorporated with a capital of $50,000 to do a general garage and sales agency business, including dealing in motor trucks, by J. E. Milner, P. E. Mooch, A. E. Mitzel, H. V. Briggle and M. W. Richards, Jr.

Howard & Wilkinson, Central Ohio agents for the Buick and Welch, have taken the agency for the Rapid Commercial car, manufactured at Pontiac, Mich.

Many Enter Dead Horse Hill Climb

Worcester, Mass., May 30—Preparations are being made to accommodate from 25,000 to 50,000 spectators at the annual hill climb of the Worcester Automobile Club, Saturday, June 4, on Dead Horse Hill. The contest is the biggest event of its kind in New England and always attracts an unusual amount of interest throughout that section.

Twenty-one events are carded and the entries to date include the following: Houpt-Rockwell, events 1-A, 9, 16-B, 18 and 19; Buick, event 6-A, driver, Duncan Hooker, Jr.; Buick, 10-model, event 12-B; Alco, events 15-B, 18-B, 19-B, Harry F. Grant, driver; Maxwell in 12-B, Thomas Costello, driver; Maxwell in event 6-A, Martin Doeley, driver; Babcock Electric, event 21, F. A. Babcock, driver; Warren-Detroit, events 6-A and 12-B; Model 100 Marquette, events 9 and 15-B; Fiat-150, in several events with Caleb Bragg at the wheel; Cole 30, in several events and an entry from the Oakland Motor Car Company.

C. Howard Gillette, president of the Automobile Club of Hartford, has been selected as referee.

Toledo, O., May 30—Frederick E. Barker, sales manager of the Willys-Overland Company, will retire from this interest on June 1. His future plans are not announced.

Interesting Items from Buffalo

BUFFALO, May 31—The Dixon Motor Car Company has made extensive alterations and improvements in its store on Main street, Buffalo. The basement of the large store has been cemented and will be used as a showroom and repair department, and an elevator, which will carry the largest makes of motor cars, has been installed. The company is planning to erect a one-story garage in the rear of the store.

The United States Auto Station Company has filed incorporation papers with the County Clerk of Erie, the capital stock being $5,000, to engage in general garage business. The principal stockholder is Frank J. Rohr, of Rochester, N. Y. The other directors are John A. VanArsdale and Warren Willett, of Buffalo.

The Pierce-Arrow Motor Car Company, the E. R. Thomas Motor Company, and F. A. Babcock, are among the contributors to the $100,000 fund being raised by the Chamber of Commerce and Manufacturers' Club for the purpose of boosting Buffalo and attracting large plants and conventions to the city.

A big motor car meet will be held at the Fort Erie, Ont., race-track, just across the river from Buffalo, on Friday and Saturday, June 10th and 11th, under the joint auspices of the race-track management and Buffalo interests.

The work of preparing the track for the races has already been begun.

Chairman Orson E. Yaeger, of the Contest Committee of the Automobile Club of Buffalo, has announced that the club is preparing plans for a 4- or 5-day reliability contest.

Records Fall at Indianapolis

(Continued from

hopes, for neither Dawson nor Harroun figured in the fight from this point on. Harroun never got past 80 miles, and at 90 miles Kincaid had the lead with Merz almost 2 minutes behind, while Lynch had worked up past Dawson. This order prevailed at the end, Kincaid winning in 83:43.12; Merz second, 85:44.15; Lynch third, 88:41.07, and Dawson fourth, 93:53.27.

The 5-mile free-for-all for the Indianapolis motor speedway helmet, a new trophy which carries with it a cash prize of $100 and a salary of $50 a week to the holder, brought out a rare field, among which were the two big Buicks with the 6 by 5 1-4-inch cylinders, which had been ruled out of the stock-chassis class; Bragg in the Fiat, Kerscher in the Darracq, Harroun in the Marmon six, Aitken in the new National 70, Kincaid in the six-60, and Lytle in the American. Young Bragg jumped the field from the pistol and had a nice lead of 50 yards going into the backstretch, with Burman in one of the Buicks following. From this point on the race was between these two and it looked as if Bragg held the whip hand. Burman did not gain much on the amateur, who came into the stretch for the last time with three lengths advantage. Then he suddenly slowed and Burman passed him like a flash, landing the helmet comfortably, the Fiat finishing second. It was said spark plug trouble put an effective brake on the Fiat. Burman's time, 3:37.24.

INDIANAPOLIS, IND., May 28—Twice raced for, it was not until to-day that a winner was evolved for the magnificent Wheeler & Schebler cup, said to be worth $10,000 and undoubtedly the most costly cup ever put up for any kind of a sporting competition. Now the first leg on the towering trophy is held by the Marmon people through the plucky efforts of Ray Harroun, of Chicago, who guided the Marmon six-cylinder Wasp 200 miles in 2 hours 46 minutes 32 seconds at an average speed of 73.05 miles an hour, defeating a rare field, which included the best cars now racing on American tracks. Nineteen cars started.

The Jackson, driven by Lynch, went the entire 200 miles without a stop of any kind, while Harroun's Marmon drew up at the pit only once and that was to take on oil and gasoline.

At the gun Arthur Chevrolet jumped out, and for the first few rounds he had a comfortable lead over the field, but Harroun, running on a schedule and as calm as if he were taking a spin on the boulevards, commenced to creep up yard by yard until at the 10-mile post he only was 4 seconds behind the leader At 15 miles he decided it was time to play his hand and at the tape he shot by the 16 B Buick and took the lead. From that point on he never was headed and at no time was he in danger of letting go his hold on the pacemaking position.

At the half century the order was Harroun, A. Chevrolet and Fox in the Pope. From this time on there wasn't much to vary the monotony of the long grind, and when the finish came it showed Harroun two laps to the good, with the other finishers, Lynch, Aitken and Chevrolet, in the order named.

Summary of the 200-mile race for the Wheeler & Schebler Cup.

page 1023.)

INDIANAPOLIS, May 30.—To-day's events, which were witnessed by 60,000 spectators, were characterized by the breaking of one Speedway record in the mile and kilometer trials, Barney Oldfield, in his 200-horsepower Benz, covering the kilometer in 21.45 seconds, the previous mark being 25.13 made by Caleb Bragg in the 90 Fiat at Los Angeles. In the mile trials Oldfield established a new American speedway record of 35.63 which was under his mark of 36.22 made on the Los Angeles motordome.

In the 160-230 class at 10 miles, Chevrolet with his model 10 Buick set a new mark of 9:03.60, the old figures being 9:49.46. In the 301-450 class, 10 miles, John Aitken in a National 40 went the distance in 7:57.08; former best, 8:08.98. Oldfield broke another record with his Knox Six in the 5-mile event, 451-600 class, going the distance in 4:01.36; former mark of 4:03.24.

Automobile Activity Around Boston

BOSTON, May 30—Judging by the manner in which the owners of private cars are responding to the call sent out by Chester I. Campbell, of the Boston Automobile Dealers' Association, for machines to take the blind and crippled children on an outing June 8, the affair will be a big success. In addition to cars some people have sent checks to Mr. Campbell so that he may hire additional machines. The Boston Automobile Dealers' Association has given $150 and members of the Association will supply about 50 machines. It is expected that more than 200 cars will be used on the outing and sports have been arranged for the drivers of machines under the direction of Thomas J. Burke, a famous athlete, who represented America at the Olympic games.

Four garages in Cambridge, just across the river from Boston, were sold last week to motor dealers in Boston and a fifth is now under consideration. They were erected some time ago by a real estate dealer, and were speedily occupied. E. D. Dodge Motor Company, Boston representatives of the Pope-Hartford and Waverley electrics, bought two buildings with 20,000 square feet of land, all assessed for $43,000. A. P. Underhill Company, Knox agents, bought one with 10,000 feet of land for $18,000, and a fourth was sold to A. C. Plummer, who represented a motor company at present not ready to move there. The price was $16,500. The Whitten-Gilmore company are negotiating for another of the buildings which they occupy at present. They are all one-story buildings built purposely for garage and repair work and minus posts.

J. W. Maguire, Boston agent for the Pierce-Arrow, is looking about for a place on which to build a new garage and repair shop, having outgrown his old quarters on Harcourt street.

Plans are under way to have a number of the Bay State A. A. members resume their annual outings to Rye Beach, N. H., where they formerly went early in the summer each year. The date planned is June 17, a holiday in Massachusetts, which comes this year on Friday, allowing a run of at least three days.

The Haynes car is again represented in Boston after a lapse of nearly a year. George H. Hudson, of the Hudson-Colby Company, agents for the Herreshoff, has taken the agency, having Eastern Massachusetts for his territory. C. S. Henshaw, now manager of the Boston branch of the Thomas, formerly handled the Haynes in the Hub.

Suits Settled: Reorganization Coming

TOLEDO, OHIO, May 30—Suits filed against J. N. Willys and the Willys-Overland Company at Indianapolis last Monday have been amicably adjusted and will be withdrawn without further trouble. Two suits were filed, one by P. C. Forbes of Indianapolis, in the County Court, alleging that Willys is a resident of that city, and the other, by Henry F. Campbell, in the Federal Court, claiming that the defendant is a resident of Toledo. Injunctions and an accounting were demanded.

President Willys stated that the difficulty arose because of disgruntled stockholders who have not been in sympathy with the business policy of the concern, and who had offered to dispose of their stock to him for $2,000,000. "This proposition I flatly refused," he said.

"Their actual investment with me was $40,000 and I told them I would not stand to be held up. I offered them $450,000 for their stock in the sales company, but they declined to accept this. I finally compromised rather than engage in prolonged litigation. I now own all but 243 shares of the 20,200 shares of the different companies. These 243 shares are in the possession of the men who are working with me in the company in Toledo.

"I am going to reorganize all the companies into the Willys-Overland of Toledo. The capital of this company is now $2,000,000, of which $1,200,000 has been issued. The other $800,000 is to be issued to the Overland Automobile Co., of Indianapolis, and when that is done, the latter concern will be turned over to the Toledo company, making but one corporation with a capital of $2,000,000, with $100 as the par value of each share."

The Ohio Motor Sales Co., of Toledo, was this week incorporated with a capital of $10,000. The new concern will have the local sales agency for the complete line of Hupmobile cars. Rooms have been secured just off Madison avenue on Erie street, and the place is now being remodeled and put in shape for occupancy within ten days. C. J. Osborn will have charge of the business. William Pratt will be assistant manager.

Sheridan Hill Climb—Ingenious Handicapping Rules

(Continued from page 993.)

The conditions under which the hill climb was conducted were ideal. The weather was perfect and the hill itself could not have been further improved for the occasion. A large crowd of enthusiasts and interested persons from Fredonia, Brockton, Dunkirk, Forestville and other towns was on hand to witness the contest, while a large party of Buffalonians formed part of the line of spectators on either side of the road.

The system of scoring was so different from the method used ordinarily that it was the subject of general comment. The opinion among the officials who had charge of the event seemed to be that the alteration of some detail in the matter of crediting the contestants on the various sections of the hill might bring about still more equitable conditions as far as the larger cars were concerned. But on the whole, the working of the plan in an event where classification was not resorted to, is considered most auspicious for a beginning of such a revolutionary move.

The extreme steepness of the hill resulted in numerous spectacular features during the climb, and the whole affair may be put down as satisfactory from the viewpoint of the spectator; fairness to the entrants and as a thorough test of the climbing ability of the cars and their general utility in traversing heavy grades under normal and extraordinary conditions.

Points Made Against Cars Under New Plan

NAME OF CAR	H.P.	Cylinder Bore	Piston Stroke	Car Model	Entrant	Driver	Cylinder Volume	Time First Contest Seconds	Points First Contest	Points Second Contest	Final

U. S. Motor Company Absorbs Stoddard-Dayton

DETROIT, May 30—With the news given out here on Saturday last of the absorption of the Dayton Motor Car Company of Dayton, O., by the United States Motor Company, it was also stated that the plans of the latter were complete, and that from now on attention would be paid entirely to the work of getting out cars for next year, for which the plans are unusually ambitious.

The latest company to be absorbed, the Dayton Motor Car Company, is a very large and flourishing one as the estimate of its worth, $2,500,000, will go to show; as well, also, the output for the current year, namely 8,000 cars, ranging in price from $1,500 to $3,500; while this firm also controls the Courier Company (which is included in the sale to U. S. Motor Company), the latter turning out 1.500 Courier cars.

Now, that the organization is complete, the roster shows that it comprises a total of sixteen plants, now built or building. These are: Maxwell-Briscoe Company, five; two at Providence, two at Tarrytown, one at Newcastle; Dayton Motor Car Company, three; two Stoddard-Dayton, and one Courier at Dayton; Brush Runabout Company, two, both in Detroit; Briscoe Mfg. Co., two; one in Detroit, and one in Newark, N. J.; Alden-Sampson Mfg. Co., two; one in Pittsfield, Mass., and one just started in Detroit; Columbia Motor Car Company, one in Hartford, Conn.; Gray Motor Company, one in Detroit.

These sixteen plants now employ 12,500 men, which will be increased to nearly 17,000 for 1911. This large number of employees will be needed to care for the enormous production, relative to which Benjamin Briscoe, the head of the enterprise, is quoted as follows:

"We expect to produce between 50,000 and 60,000 cars for 1911, or a total business of approximately $55,000,000, the employees at the Columbia plant being doubled, those at the Dayton works being increased to such a number as will enable us to double the number of Courier cars now turned out, while all the other factories will be correspondingly increased."

The new Detroit plant for the Alden-Sampson Mfg. Co., which will be the real headquarters of the power wagon end of the United States Motor Company, will consist of one long narrow single story building of reinforced concrete construction, with a smaller separate office building. The main shop building will be 1,000 ft. long by 175 ft. wide. Commenting on the Detroit situation, Frank Briscoe said:

"In the various Detroit plants we will employ over 6,000 men by the first of the year, we are going to build a great big addition to the Brush plant on Oakland avenue that will be shaped like a letter U. Each leg of this will be 1,050 ft. long and the connecting link 450 ft. long, the whole structure being 152 ft. wide, one story in height and of the saw-tooth roof construction, which gives the maximum amount of interior light and convenience for all phases of manufacturing."

Sentinel Trophy Route Selected

MILWAUKEE, May 30—Contestants in the first annual Wisconsin tour for the Milwaukee *Sentinel* trophy, under auspices of the Wisconsin State Automobile Association, will travel one of the most difficult routes ever laid out for a motor tour, according to M. C. Moore, president of the W. S. A. A., who has just returned from the pathfinding tour in a Rambler.

It took Mr. Moore seven days to blaze the trail for the five-day tour. Difficulties encountered at this time, however, will not be faced by the contestants, because the pathfinding was done in May and the tour will be run July 18 to 23, inclusive. The roads which were in poor condition when the pathfinder passed will be entirely different for the tour.

The longest run will be on the fourth day, when 210 miles will be covered from Chippewa Falls to Appleton. The first night control will be Madison; the second, LaCrosse; the third, Eau Claire-Chippewa Falls; the fourth, Appleton, returning to Milwaukee on the fifth day. A schedule of twenty miles an hour will be maintained. Mr. Moore will act as pilot.

The Wisconsin Motor Manufacturing Co., of North Milwaukee, Wis., has increased its capital stock from $100,000 to $200,000.

The Franklin Automobile Co., of Milwaukee, Wis., has filed an amendment to its articles of incorporation changing the name to Franklin Auto & Supply Co. Henry Danischefsky is president of the company. The headquarters are at 321 Fourth Street, Milwaukee. This concern has just taken the agency for the Chase motor truck and has handled the Franklin, Regal, and Babcock electric.

Phillip Kellar, of Kaukauna, Wis., has been granted letters patent on a new type of safety brake for use on motor cars in place of the emergency brake. The appliance consists of two steel shoes which drop to the ground instantly when released, lifting the rear wheels from the ground and compelling the car to slide on the shoes.

The Abresch-Cramer Auto Truck Co., of Milwaukee, Wis., has moved into new and larger quarters in a five-story reinforced concrete structure.

Clubmen Finance Road Repair

RICHMOND, VA., May 30—The Richmond Automobile Club, through a committee composed of Dr. Angus Nichols, R. B. Alport and E. C. Pelouse, donated $600 to the road supervisors of Chesterfield County, Va., for use in completing the road improvements between Petersburg and this city.

The macadamizing of the thoroughfare has been completed all but about three miles, and the donation is to be used for this stretch.

Members of the club state that they would have given a larger amount, but they recently became discouraged by the frequency of arrests for alleged violations of the speed laws, made by county authorities. It is understood that the rulings of the authorities are to be modified.

Quite a number of motorists here met the advance cars in the Washington *Post* Test Run when they arrived to-day, and the Richmond Automobile Club turned out with a car bearing the club officials. The contestants were welcomed to the city. and entertained for some time before the return trip to Washington.

Clubmen Work Hard on Roads

SIOUX FALLS, S. D., May 30—Automobile owners of Pierpont, Day County, S. D., have demonstrated what can be accomplished by a practical good roads campaign. Every morning for the past two weeks a big delegation of autoists left Pierpont in autos for the country roads which lead to the town, equipped with picks, crowbars and shovels. As a result the little town of Pierpont is approached by one of the finest road systems in the country and one that is bringing this section much notice throughout motordom of the adjoining States.

The Beloit (Wis.) Automobile Club plans to hold its first annual sociability tour of two days in June. It is planned to run to Janesville, Jefferson, Watertown, Waupun, Waukesha and Milwaukee on the first day, returning via Racine, Kenosha, Geneva, Delavan and Janesville on the second day.

Good Roads Tour Offers Great Promise

WITH a Columbia, Gordon M. Wagner will be pacemaker for National Good Roads tour, starting from Atlanta June 6 and finishing at New York June 14. With the mails of Tuesday and Wednesday still to be accounted, the entry list now contains sixty-two contesting and eight official cars. The entry box closed June 1. The list is as follows:

OFFICIAL CARS (NON-CONTESTING)

Entrant's Name and Address	Make of Car
James R. Gray, Atlanta	Pierce Arrow
Major John S. Cohen, Atlanta	White Gasoline Car
R. H. Johnston, the White Company, New York	White Steamer
Matheson Automobile Company, New York	Matheson "Silent Six"
Ray M. Owen, for R. M. Owen & Co., New York	Reo Roadster
Columbia Motor Car Company, New York	Columbia
A. D. Corwin, Buick Motor Company, New York	Welch-Detroit
Ajax-Grieb Rubber Company, New York	Lozier (Briarcliff model)

CONTESTING ENTRANTS

Entrant's Name and Address	Make of Car
Beaumont Davidson, Atlanta	Packard
W. J. Stoddard, Atlanta	National
Colonel J. J. Woodside, Atlanta	Thomas
R. E. O'Donnelley, Atlanta	Packard

R. G. Scruggs, Waycross, Ga	E-M-F
W. P. Walthall, Atlanta	Moon
Mayor Gaston Gunter, Montgomery, Ala	White Gasoline Car
W. H. Peacock, Cochran, Ga	Cadillac

Asks Court to Withdraw Reward

WILMINGTON, DEL., May 30—If the Delaware Automobile Association can induce the Levy Court of New Castle County to withdraw a standing reward offered by the court some time ago, of $15 for the arrest and conviction of automobile drivers who exceed the speed limit, it is the belief of the officers of the association that its new plan for enforcing the law can be made successful.

The association took the matter up with the Levy Court at its last meeting, requesting a withdrawal of the reward, temporarily at least, on the ground that it is an incentive to activity on the part of unscrupulous officers and others who might be guilty of persecution, in order that the association may carry out its policy of dealing with offenders in an orderly and systematic manner.

Some time ago the Levy Court agreed to share with the association, to the extent of $150, the expense of tripping up and punishing speeders, and under this agreement the association has mapped out measured stretches in several different parts of the county, the locations known only to the association officers, and there are watchers, who are also unknown, except to the officers. These watchers have reported a number of violations and the violators are receiving warning notices, and if they do not heed these they will be prosecuted. The plan is working well, but there is an indication of its being interfered with by the standing reward.

The Levy Court has taken the matter under advisement and will probably give an answer next week.

Callan Bill Signed by Hughes

ALBANY, N. Y., June 1—Governor Hughes signed the Callan bill yesterday. The bill provides registration of automobiles and licensing of chauffeurs, and it is estimated that the revenue to be derived from its operation will be in the neighborhood of $1,500,000 annually. The new law goes into effect August 1.

Hoosier Automobile Items

INDIANAPOLIS, IND., May 30—A receiver has been appointed for the Indiana Motor and Manufacturing Company, which has its principal offices in this city and its factory in Franklin. The Security Trust Company has been named as receiver. William H. Freeman, a stockholder, claims indebtedness of $750.

Inability to get parts to complete several hundred cars that are ordered is said to be responsible for the company's difficulty. It is said that the company has orders for about 700 cars, which it cannot fill and deliver from lack of parts. John E. Billheimer, Auditor of State, is president of the company.

The Cole Motor Car Company has leased the building at 820-822 East Washington street that has been occupied by the Reliable Auto Exchange. The building is 50 by 200 feet, three stories high and fireproof, and will be used by the Cole Company for painting and finishing.

The Reliance Motor Truck Company, of Owosso, Mich., has opened a sales branch here, taking temporary quarters with the Buick Motor Company in East New York.

The Wilcox-Clemens Auto Company has moved into new quarters at 19 W. Ohio street, in a building just completed. The company has the agencies for the Speedwell and Clark cars.

This city was a control last Tuesday for a "Roadability" run given from Terre Haute to Indianapolis and return, under the auspices of the Terre Haute Motor Club, the prize being a trophy offered by the Terre Haute *Tribune*. There were nineteen contestants, no attempt being made at speed, the plan being to finish closest to a secret schedule. One of the contestants was Paul Cox, a fourteen-year-old boy, who drove an Overland car. The distance was 144 miles for the round trip.

Club Will Improve Highways

NEBRASKA CITY, NEB., May 30—An automobile club was formed here last week, the object of which is to promote good roads. An effort will be made to secure every autoist.

Kingston Welcomes New Automobile Maker

KINGSTON, N Y., May 30—W. A. Wood Automobile Manufacturing Company, a new corporation of the State of New York, is about to enter the automobile manufacturing field for the manufacture of high-grade pleasure cars and trucks. They have purchased the Peckham Car & Truck Company's plant at Kingston, N. Y., comprising seven acres of ground, with five buildings fully equipped with machinery and power plant, the main building being 325 x 75. The plant is situated on the junction of the West Shore and Ulster railroads, and has three separate branch tracks entering the plant. Some changes of equipment will be made to adapt the plant to the special work in hand, and these are under way, and the plant will add its contribution to the production of cars for 1910. The production will be high-grade pleasure cars, 30 to 60 horsepower, in every style, with chain or shaft drive, and a 30 horsepower chassis for runabout or touring car or town car service. An important part of the production of the new plant will be the manufacture of high-grade commercial trucks, and for this purpose an arrangement has been made with the Commercial Cars, Limited, of England, manufacturers of the Commer truck, for the reproduction of this truck under the existing designs, with slight modifications, adapting it to American use. The sample new truck was received from the Custom House last Friday at 4.30, made its initial trip to Poughkeepsie that evening, arriving at 10.30, and in the morning proceeded to Kingston. The new model for the production of touring cars is also ready for duplication.

The city of Kingston gave the new industry a rousing reception at the Armory on Friday evening under the auspices of the Kingston Chamber of Commerce. The hall was filled with enthusiastic business men. An address of welcome was made by the Mayor of Kingston, followed by congratulatory responses from representatives of the city and of the new industry.

The project is regarded as something more than a mere civic gain to the community by the progressive citizens of the city.

Fig. 1—The new automobile which brought about the demonstration and is the basis of manufacture

Fig. 2—The commercial truck which will have a place in the large new industry

Auto and Aero Club Elects Officers

MONTREAL, May 30—The annual meeting of the Automobile and Aero Club of Canada was held on Saturday and the following officers elected for the ensuing season: President, F. H. Anson; vice-president, L. C. Rivard; secretary-treasurer, G. A. McNamee; directors, J. A. Mackay, H. W. Pillow, C. F. Smith, Duncan McDonald, A. L. Caron, A. J. Dawes, Wm. Carruthers, and Eugene Tarte.

The question of establishing a country clubhouse was brought forward and a committee appointed to look into the matter.

Much has been accomplished in the matter of road improvement. The chief work of the club, the improvement of the International Highway between here and Rouse's Point will be continued this year. The distance is 50 miles. It is estimated that thousands of dollars are lost to the country each year through the bad road between St. John's and Rouse's Point, which prevents many automobilists from coming to Canada. The club hopes in time to persuade the government to establish a State road through this district.

Ground Broken for Velie Plant

MOLINE, ILL., May 30—Ground has been broken for the new plant of the Velie Engineering Company. The building will be located between Third and Fourth avenues and east of Twenty-fifth street. The present plans contemplate a building 600 feet long, 4 stories high and 80 feet in width. It will be of reinforced concrete similar to that occupied by the Velie Motor Vehicle Company. The new corporation has secured sufficient ground for four buildings of the size mentioned.

Publicity for New Association

Letters asking for financial support to the recently formed Association of Motor Car Manufacturers have been sent out pretty generally by the legal representatives of that body. The following is a copy of a circular letter signed by Henry C. Walter, Detroit, under date of May 19.

"In view of the fact that you were invited to attend meetings held in Detroit, for the purpose of taking steps looking to united action on the part of the independent manufacturers of automobiles, in combating the unfair methods of the A. L. A. M., you are informed that all plans were perfected on Monday last. Numerous counsel have been engaged, and action started along the general lines suggested in my previous communications.

"The companies that have been sued, most of which were represented, have decided to pay all the expenses of the present litigation.

"If those that have not yet been proceeded against care to contribute to a fund to be devoted solely to educational advertising, they may remit such amount as they desire to J. B. Chaddock, Treasurer Finance Committee, Association of Motor Car Manufacturers, Moffat Building, Detroit, Mich. Remittances may be made by companies that are not members of the association. From $250 to $500 from each company will be acceptable.

"I send you under separate cover a copy of a full-page newspaper advertisement now being run by the A. L. A. M., which should prove of interest to you.

"(Signed) HENRY C. WALTERS.
"Special Attorney, Association of Motor Car Manufacturers."

In the Realm of the Makers

R. H. Johnston has been appointed manager of the New York branch office of The White Company and will enter upon his new duties at once. Mr. Johnston has been advertising and publicity manager of the company since the early days of the industry and his numerous activities in that position have made him well known to the motoring public. Under the pen names of "Pathfinder" and "Pioneer" he has been a frequent contributor to the magazines on touring subjects. He has devoted much time to searching out and describing touring routes, and the information thus secured has been issued in the form of the White route books, which have proven exceedingly useful and popular.

Mr. Johnston entered the services of The White Company in time to take part in the famous New York-Pittsburg endurance run of 1903 and he has been active in tours and public contests ever since that time, frequently serving as an official. He has also been an active factor in the cause of good roads and has been closely identified

R. H. Johnston, New York Manager of the White Company

with the movement of building a national highway between New York and Atlanta. He was one of the prime movers in the New York Motor Club, now defunct, and the entertainments which he organized and presided over have not yet been forgotten.

Two years ago Mr. Johnston brought a test case to determine the rights of non-resident motorists in the State of New Jersey. Although the Supreme Court of the State finally decided against him, the litigation served to emphasize the unjust provisions of the original Frelinghuysen law, and that law was thereupon amended and modified in several important particulars.

Mr. Johnston was born and bred in New York and thinks that Broadway is the garden spot of the universe. When he moved his office from New York to Cleveland last Fall there were many who predicted that he would soon return—a prediction which events have verified. There will be a host of friends to welcome him back.

Moon Automobiles Doing Missouri Roads

Among the Various Agencies

The Vale Automobile Company, of Beloit, Wis., is handling the Marion.

Rix & Company, of Calgary, B. C. are named as the Winton agents in that vicinity.

The Selden Automobile Company has opened a Pittsburgh agency at 320 Liberty avenue.

The American Garage in East Market street, Indianapolis, has taken the agency for the Royal Tourist.

Joseph Striker has just been added to the local sales force of the Buffalo agency of the Franklin Automobile Company.

The Ferromatic Tire Company, of Kansas City, Mo., has established its principal headquarters at Manitowoc, Wis.

The Southern Vehicle & Auto Company, of New Orleans, has taken the agency for the Lozier line of cars for that city and vicinity.

The Automobile Equipment Company has taken on the agency in Baltimore for the Kissel Kar. The firm is located at 2207 Madison avenue.

Barrett Bros., of Albany, Ore., have secured the agency for the Overland cars. White & Scheer have secured the agency for the Overland at Canby, Ore.

The Smith Auto Company, of Birmingham, Ala., has contracted for the Halladay line, manufactured by the Streator Motor Car Company, of Streator, Ill.

H. M. Meyer, Pittsburg, has been given the agency for the Automobile Air Shock Absorber in that city. Edgar A. Dossert, Philadelphia, has been appointed the agent for that vicinity.

The Mitchell-Lewis Motor Company, of Racine, Wis., has started construction work on a large warehouse of steel, concrete and brick. The building will be two stories high and will be used to store finished cars awaiting shipment.

D. D. Cummings, of Minneapolis, Minn., has opened a public garage in the Bailey building at Ashland, Wis.

The Sawyer Implement Company, of Sturgeon Bay, Wis., is equipping a part of its building into a garage, which will be in charge of Edward Hunt, an expert motor car mechanic.

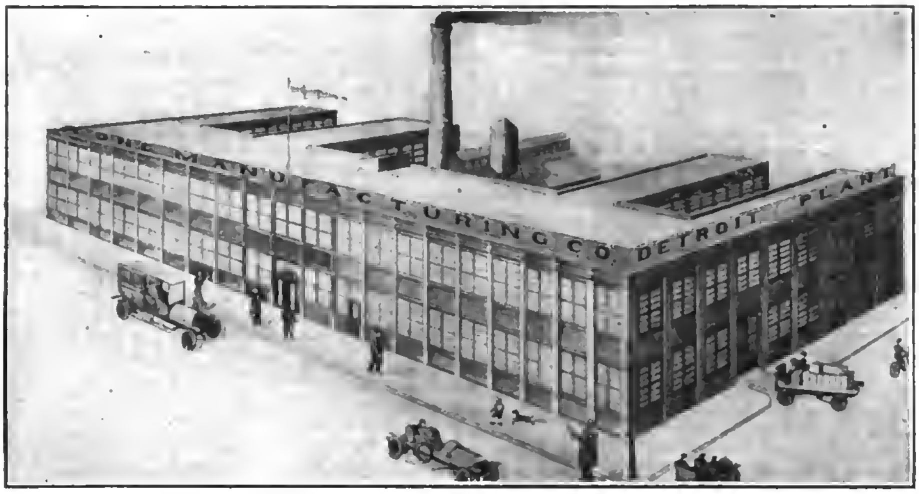
The Inter-State Automobile Company, of Muncie, Ind., is highly pleased with the showing of its Class B entry in the recent Harrisburg run. The car was awarded first prize in that class.

E. E. Short has opened an agency for the Inter-State in Indianapolis under the name of the Interstate Motor Sales Company and has located at Fort Wayne avenue and Tenth street.

The Findlay Motor Car Company, of Findlay, O., was this week incorporated by A. L. Welch, M. C. Mulball, Roy H. Hunter, J. C. Brooks and S. Gilfether. It will have a capital stock of $300,000. It is expected that the company will get under way shortly and push things to the limit.

The E-M-F Company is planning to establish a branch in Omaha for the E-M-F and Flanders cars. If this is done it is announced that a large new building will be erected here this Spring.

C. C. Hildebrand, Assistant General Manager of the Chalmers Motor Company



New Long Radiator Plant at Detroit, Mich.

Frank J. Flanigan has established a Simplex agency in Seattle. His agency contract covers the States of Washington and Oregon, and Seattle will be the distributing headquarters.

The Chittenden Motor Car Company has taken the Buffalo agency for the Lion motor cars. All business done in the handling of these cars will be under the name of the Lion Sales Company.

The Brooke Automobile Company, of Kansas City, has opened an agency in Omaha at 2318 Farnam street, under the management of Paul C. Gee. The company handles the Lexington car.

Charles W. Larson has purchased the garage at 524 West Main street, Waukesha, Wis., and will operate it under the name of Auto Supply Company. Mr. Larson has the agency for the Overland.

The Shaffer Manufacturing Company, agents for the Pullman car, will erect a new garage at 408 North Calvert street, Baltimore.

The Champion Company, a Boston concern engaged in the manufacture of spark plugs for automobiles, will remove to Toledo. The machinery for the company is expected to arrive in a week or ten days. The concern will supply spark plugs for the Willys-Overland Manufacturing Company.

Lee Counselman, Vice-President and General Manager of the Chalmers Motor Company

O. H. Hansen and Theodore Tellefson have leased the Scobie Building, at Cambridge, Wis., and will open a garage and salesroom for the Buick, Ford, Oakland, White and Oldsmobile.

Mortimer Reeves has been appointed contest manager of the United States Motor Company. Mr. Reeves is a brother of Alfred Reeves, general manager of the A. L. A. M.

H. E. Halbert, proprietor of the Garfield Park Automobile Garage, Chicago, denies the reports that have been circulated that he has sold the property or contemplates any change in its management.

The Streator Motor Car Company, of Streator, Ill., commenced the erection of two machine shops, each 75 by 400 feet. These buildings are to be of the latest mill construction, and machinery is already on the ground for equipping them throughout.

Hockaday Brothers have opened a motor supply house in temporary headquarters at Wichita, Kas., having disposed of their department of bicycles and sporting goods. L. C. Graham has been engaged as manager of the firm's auto accessories department.

The General Tire Company, of Cincinnati, was incorporated recently with an authorized capital of $10,000, to deal in automobile tires and accessories, with A. V. Boettles, J. H. Marvin, Phil Eid, A. J. Braumvart, Jr., and John L. Boake as incorporators.

The Michelin Company has discontinued the retail department of its tire agency in Buffalo, and attention will now be devoted exclusively to the wholesale trade. The retail business has been placed in the hands of the Chittenden Motor Car Company, located at 906 Main street, Buffalo.

General Trade News.

Owners of automobiles in Buffalo have been informed that the Board of Aldermen of Nunda, N. Y., has adopted a speed limit law. Vehicles are limited to 10 miles an hour through the village. Any violation will be punished by a fine of not less than $5 nor more than $50.

The Taxicab Co. of America has purchased the building formerly used by the Henkel livery, Detroit, and is equipping it as a garage. The Henkel barn recently was the scene of a dispersal sale of horses and cabs, the business being given up as no longer profitable, since the advent of the taxicabs.

E. B. Finch has resigned as manager of the technical department of the Chalmers Motor Company, to become Cleveland distributor of Chalmers cars. Last Monday his fellow employees and the company joined in giving him a farewell dinner, at which time he was presented with a fine shotgun as a testimonial.

J. B. Long, President of the Long Manufacturing Company

The Cole Motor Car Company, of Indianapolis, has reorganized the Chicago sales and distributing agency. G. W. Stephens and F. S. Cropley have formed a company to be territory distributors of the Cole 30, and will be temporarily located in the Standard Automobile Company. In the near future they will remove to much more commodious quarters.

Michelin Tires on Winners—In the equipment of the first, second, third and fourth cars to finish in the Wheeler and Schebler and Prest-o-Lite contests on the Indianapolis Speedway, were included Michelin tires. On the Marmon winner and the Jackson car which finished well up, no tire changes were required in the former event. On almost all the cars that won national championships in the Decoration Day events the Michelin tires were in evidence.

Prominent Automobile Accessories

ELECTRA SPARK PLUG

It may not be generally understood that the electromotive force, which is available from a magneto or a coil, is limited by the breakdown potential of the spark plug. If the spark plug will not stand up against the electromotive force of the magneto, it will be necessary to decrease the distance of the gap in the spark plug to protect the same, but it must not be forgotten that this very process is the one which limits the electromotive force of the magneto. It has not been difficult to design magnetos for high potentials; it is even possible to realize 30,000 volts, but it is quite another question to so design a spark plug as to be able to use these higher potential ways. The illustration here offered shows two types of the "Electra" spark plug, the one to the right being a modification of the standard form, somewhat lower in price, and is offered here for what it is worth. The section to the left is the standard form, in which A is the main insulator of porcelain, surrounding the electrode Q. B is the enlarged portion, which offers two abutting faces for the soft packing C1 and C2.

This packing is asbestos in character, enveloped in copper sheathing. D is a protecting insulator, also of porcelain, and the threaded portions E and F serve as the housing, F being reduced to the proper size for screwing into the cylinder. The terminal H offers a neat and substantial way out of the customary difficulty, and affords a substantial means of connecting the high potential leads to the spark plugs. This spark plug is used in France, and is about to be introduced to American autoists by M. Volpé, 136 Liberty street, New York. This type of spark plug is used in conjunction with magneto and other ignition work on divers of the better grades of foreign automobiles, and it is expected that it will prove of more than a little value on exacting American work of this character.

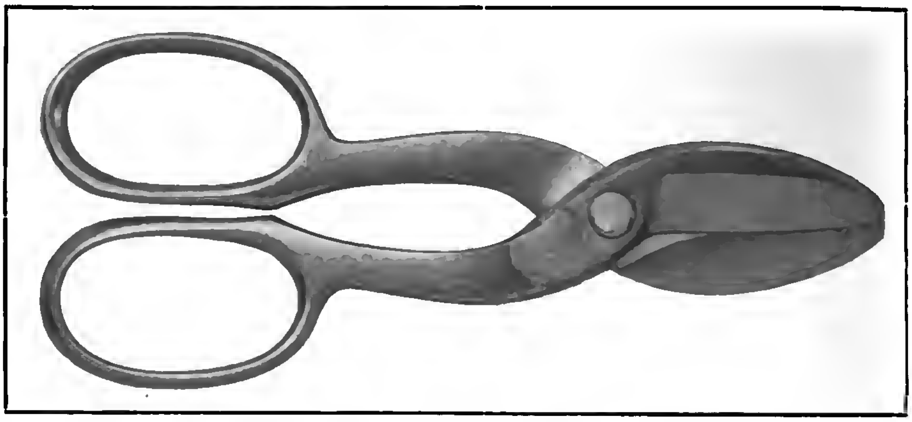


Fig. 2—Snips as used by autoists for various purposes; they are made in several sizes

SHEAR AND SNIP COMBINED

In an emergency while motoring, or, in fact, almost any time, the possession of a good strong, sharp pair of shears or snips is necessary. In case of repair work on the road the cutting of washers or gaskets on the spot may mean the saving of exasperating delay. In order to provide a thoroughly adequate tool of this description, the National Cutlery Company, of Philadelphia, has made a new type of snip which combines the principles of shears and is marketing the tool at $1.50.

The company says that the quality and finish are first rate and recommends the tool to automobile operators without hesitation. It is made with oval blades to facilitate cutting small circular washers and for performing many other kinds of emergency work.

Automobile Touring Tent—To enjoy an automobile tour through the wilder sections of the land, a good, waterproof tent of light weight and close woven texture, is about as important to the success of the trip as an adequate supply of food or gasoline. The New York Sporting Goods Company, realizing that self-evident fact, has

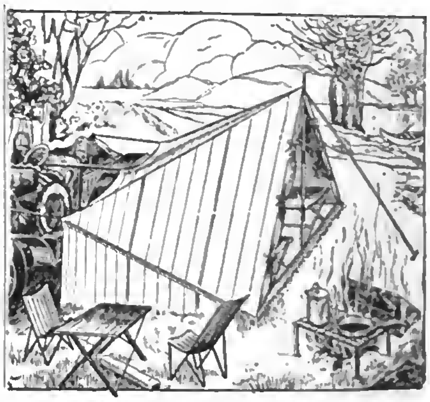

Fig. 3—"Compact" Khaki Tent

put on the market an automobile touring tent which is pronounced satisfactory in every way by the manufacturers.

It is made of khaki and is waterproofed after completion in other respects. It is reinforced with tape at the seams and is built to stand hard usage. The pole that is used with this tent is in three joints and the guy ropes are so arranged that they may be stayed either to the car or by tent pegs. The whole tent weighs only 31 pounds and can be folded into a package 36 by 7 inches, thus occupying only a small space in the car.

When the tent is raised it makes a room with nine feet frontage, seven feet high and deep, sufficient to accommodate three cots, or two cots and folding tables and chairs. Larger tents are not practicable for automobile tours, but if the party to be served is larger than four, two tents may be set facing one another.

The price of the outfit is $25, or the tent may be had separately for $16.

Vol. XXII. New York—Thursday, June 9, 1910—Chicago No. 23

The Automobile

"Good Roads"

ATLANTA, GA., June 6—Most important of the events of the year is the "Good Roads Tour," which made an early start from Atlanta this morning. The advance guard was represented by a patrol of mounted police supported by a fire wagon, and the tooting of its siren proclaimed to the world that 71 entrants, with their splendid automobiles decorated with flying banners, and bound by the tradition which is at the foundation of Anglo-Saxon success, had started to blaze the way of the Great National Highway, which is being advocated by the sponsors of this tour in the guise of the New York *Herald* and the Atlanta *Journal*, and which is to dissolve the Mason and Dixon Line, mingle the thoughts of the North and South, and cement the world efforts of the two great sections of the country for the common good.

As the roll of honor was gradually unfurled before the keen and riveted gaze of Georgia's best citizens who were assembled there to do honor to the occasion, the cars checked off, each in its proper place, all in the pink of condition, and with a certain synchronized inter-relation of the sound emanations due to the cycle rhythm of the sturdy power plants which were there as the direct representatives of the automobile engineers who work in American plants and evolve the mechanisms which are as the keystone which ties the arch fashioned from the automobile on the one hand and good roads on the other.

The music rendered up by a mass-band bade a parting farewell, the strains of which greeted the ears of the occupants of the automobiles which made up the rearguard, and the assemblage rent the air with prolonged cheers as the grand parade straightened its line for its onward march, heading for Anderson, S. C., over the route which the Columbia Pathfinder had pioneered.

Pleasant Atmosphere

After getting under way on Monday, the participants soon brought away a full realization of the seriousness of the undertaking. When the cars rolled off of Atlanta's splendid pavement, and the oil-like consistency of Georgia's clay began to coquette with the tire-bound wheels of the automobiles, skill on the part of the pilots of the cars was brought into greater prominence, and the little pleasantries which flitted over the assemblage at departure were supplanted by the more serious views which portrayed a stern reality fraught with possibilities, intermingling even dangers. As the day wore on, and the June sun began to paint the western horizon, a recount of the day's work included no accidents of a serious nature, unless, perchance, tire trouble, of which there was enough.

The Locomobile, entered by John W. Grant, was not so fortunate as the other automobiles; it skidded into a ditch, and an inventory of the damage done included a broken spring. This incident transpired at a point some 40 miles from Atlanta, but Mr. Grant had company in his misery, which included Charles T. Smith, of Concord, who

From Martinsville to Staunton, in Virginia

drove a Maxwell; also Emmett Callan, of Washington, Ga., in a Maxwell; they, too, had spring breakages to record.

From Atlanta, all along the line, the farmers gathered to witness the passing of the automobile procession. At Norcross, which is a small suburban town, there was a solid line of people, which, including farmers' teams, gathered at the crossroads, not forgetting a vast display of automobiles, which were lined up along the curb, made a brave showing.

If the Norcross citizens did themselves proud, they were staunchly supported in a thousand ways; steam whistles shrieked a welcome everywhere; negro laborers and their families paid tribute to the automobile, and the citizens of Norcross, who were represented by an enlightened committee, put up a big sign at the edge of the town, which intercepted the thousand-eyed cavalcade, and it read, "speed limit 110 miles." From Norcross on to Duluth, the ovation was never-ending, being in the main a repetition of that which went before, varying in some measure, and limited only by the ingenuity of the citizens, whose enthusiasm knew no bounds.

As an unpleasant accompaniment to an otherwise agreeable situation, such of the contestants as were less fortunate than their sportsman-like competitors, fell by the wayside, as tires became unruly. Just outside of Duluth the Jackson, No. 42, with C. D. Smith, of Albany, Ga., accompanied by Mrs. Smith, W. N. Tickner, and a pleasant party, succumbed to a puncture, and the broad smiles which illumined the countenances of the party was barely equal to the character of the illumination which was generated by four additional punctures before Auburn was reached. There were the customary number of little incidents which peppered the situation from time to time, rendering it rather the more savory, perhaps, than otherwise. The Velie car, on nearing Winder, cast up a variety of motor trouble, which lost to it a noticeable measure of time.

State Lines To Be Crossed Through Floral Arches

The friendly frontiers of the respective States will vary such monotony as there may be in divers ways. At Knox's

Working on New Road Which Leads to Winston-Salem

Bridge, in South Carolina, a floral arch was placed at Fairplay; every tourist received a postal card from the debutantes, who were voted pretty, and the noted hospitality of the South was notched up for the occasion. The 266 occupants of the 70 automobiles which are participating in the tour were so stunned by the overwhelming attention which they received at Atlanta, that when they departed at 8:30 on Monday morning, with the "God Speed" of Mayor Maddox, the latter with his staff, including Fire Chief Cummings and his "red devil," were reduced to comparative silence, but they have since awakened to the splendor of it all and they expend between times on the tour, vying with each other in praise of the great Southern metropolis and its hospitable inhabitants.

ANDERSON, S. C., June 7—The first day's run was not without its strenuous possibilities, while the path, considering it in general, was all that could be anticipated. There were wet roads to encounter, due to rain which fell in that section of Georgia on Sunday afternoon, continuing over until Monday morning.

68	NATIONAL:	F. J. Cooledge, Atlanta.
69	COLUMBIA:	John W. Mangham, Griffin, Ga.

The Schedule Beat Some of the Automobiles a Little

The first report over the wire, which has, of course, to be verified in the final sum-up, gives the cars by names as follows, as having fallen behind the schedule:

From Atlanta to Anderson, Near the Mountain House

No. 21, Pope-Hartford, entered by Preston S. Arkwright, of Atlanta, fined 50 points; No. 25, Speedwell, entered by Arthur T. Smart, of Atlanta, fined 43 points; No. 42, Jackson, entered by C. B. Smith, of Albany, Ga., fined 77 points; No. 55, Ohio, entered by M. L. Thrower, of Atlanta, fined 12 points; No. 65, Maxwell, entered by Charles T. Smith, of Concord, Ga., fined 77 points; No. 32, Locomobile, entered by John W. Grant, of Atlanta, had the misfortune to break a wheel, and just how much of a penalty will be attached to this incident, is yet to be made known. Up to midnight of the first day's run, this car had not put in an appearance, but word was received at Anderson that the car is on the move, and it should catch up before the end of the second day. No. 47, Pullman, entered by W. G. Humphrey, of Atlanta; No. 9, Lambert, entered by J. T. McNinch, of Atlanta; No. 44, Mitchell, entered by L. C. Brown, of Athens, Ga.; No. 67, Maxwell, entered by Emmett Callan, of Washington, Ga., checked in at 11:40 P. M. to-night.

The distance from Anderson to Charlotte is 158.8 miles, as the pathfinder surveyed the route. The time of running is to be a duplicate of that which obtained between Atlanta and Anderson.

Charlotte, N. C., Marks End of Second Day

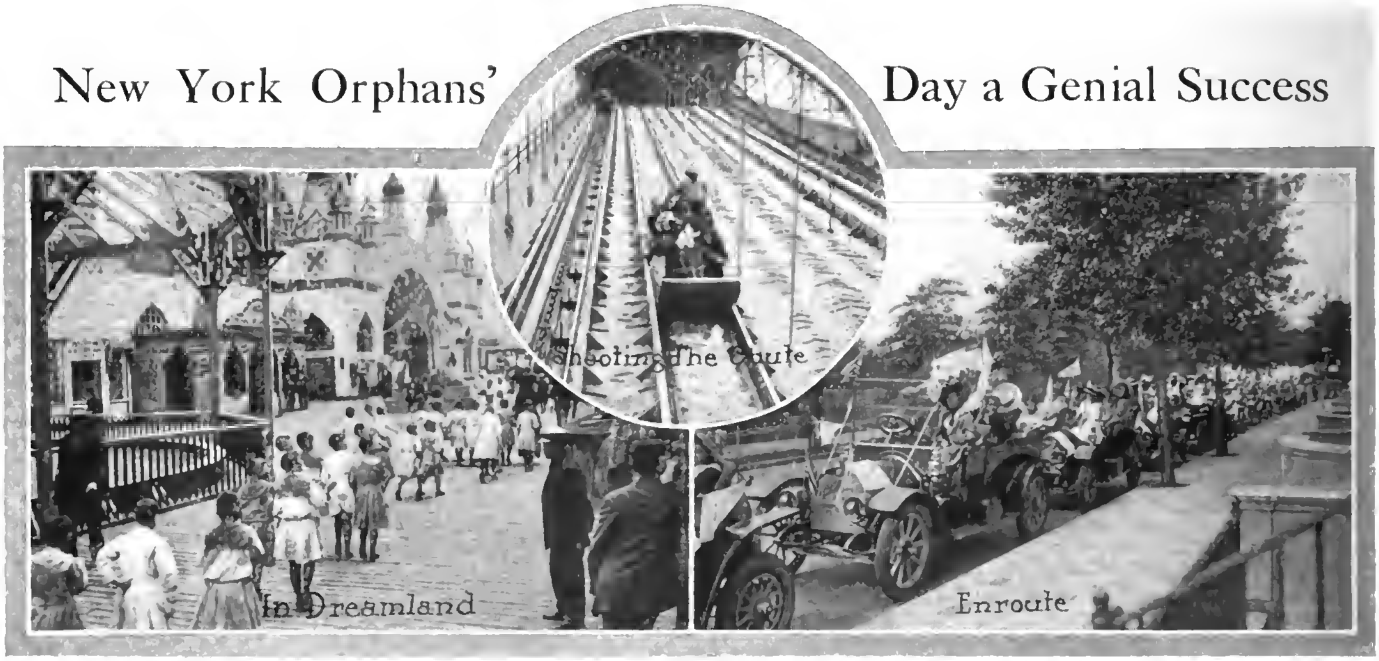
Charlotte, N. C., June 8—Common accord of the tourists voices a single sentiment; it has for its plaint the fact that Charlotte did itself so proud and offered such a wide diversity of entertainment that it was a mistake to so fix the itinerary that the tour could not linger there for at least another day. The run from Anderson to Charlotte was one of consuming interest. There was but one accident of moment; it fell to the lot of the Stevens-Duryea car, which belonged to Mrs. M. L. Barnes, of Myrtle, Ala. Approaching Greensville, at an ugly point in the road, the car broke out of control and a summary of the happenings of the time included a broken front wheel. Mrs. Barnes is making a strenuous effort to have the wheel replaced by a new one, which will have to come from Greensville.

Along the route at every point of vantage grandstands are

(*Continued on page* 1066.)

The Road to Rocky Mount Was Not of the Best

New York Orphans' Day a Genial Success



LEFT—Orphans Never Knew of a Place Like Dreamland Before. RIGHT—On the Ocean Boulevard. TOP—Shooting the Chutes

FOUR miles of automobiles, laden with 3500 happy little children, inmates of 22 of New York's orphanages, made a trip to Coney Island, Thursday. The children were the guests of the Orphans' Automobile Day Association of New York and they had a royal time.

There were 400 cars in the procession and an effort was made to maintain 50-foot intervals during the run. Aside from the fact that the truck divisions contained 32 big machines, the feature of the parade this year was the presence of 120 taxicabs in line. There were over 200 touring cars, most of them privately owned and donated for the occasion. Fifteen sight-seeing cars, three opera 'buses and several automobile stages were in line.

Some of the youngsters were picked up as far away as Yonkers, thus the ride they had was nearly 75 miles long, but the average was in the neighborhood of 30 miles.

At 10 o'clock in the morning, under unpromising weather conditions, the head of the procession began to move amid the delighted shouts of the little ones. Every car was bedecked with streamers announcing that its destination was "Dreamland" and nearly every child had been furnished with a small American flag. So when the cars straightened out over any stretch of street that was without curves, the line of automobiles had a gay appearance. Sections of the cars had been delegated to get the youngsters at the various institutions and the parade formed on the cross streets between Seventy-ninth and Seventy-second streets with the head of the column resting at Seventy-eighth street and Broadway.

The route followed was down Broadway to Forty-eighth, to Fifth avenue to Fifty-seventh, thence to Second avenue and across the Queensboro bridge and by a devious route through Brooklyn to the scene of the annual merry-making.

There were six bands in the procession and after the cars had reached their destination, the musicians furnished a variety of tunefulness for the benefit of the big crowd. Every show in Dreamland was open to the kids and they Shot the Chutes and did various other things until they were tired.

But first of all, immediately after reaching Coney, the little ones were filled up to the last notch with a tasty dinner provided by Hugh Chalmers and served in one of the immense dining-rooms of the resort. Three times the great hall was filled with the clamoring children, who were ready to do justice to a far less toothsome spread.

Col. K. C. Pardee, president of the Orphans' Day Association and secretary and general manager of the Maxwell-Briscoe Company in business life, presided. Col. Pardee was decorated with a sample of all the badges used in the parade and presented a smiling face to the little ones from above the riot of color lent by the bright badges.

Alex. Schwalbach, secretary of the association, was in direct charge of the details of the affair and spent probably the busiest day of his life in handling all the questions that arose.

It is estimated that the cars in line represented a total valuation of over $2,000,000.

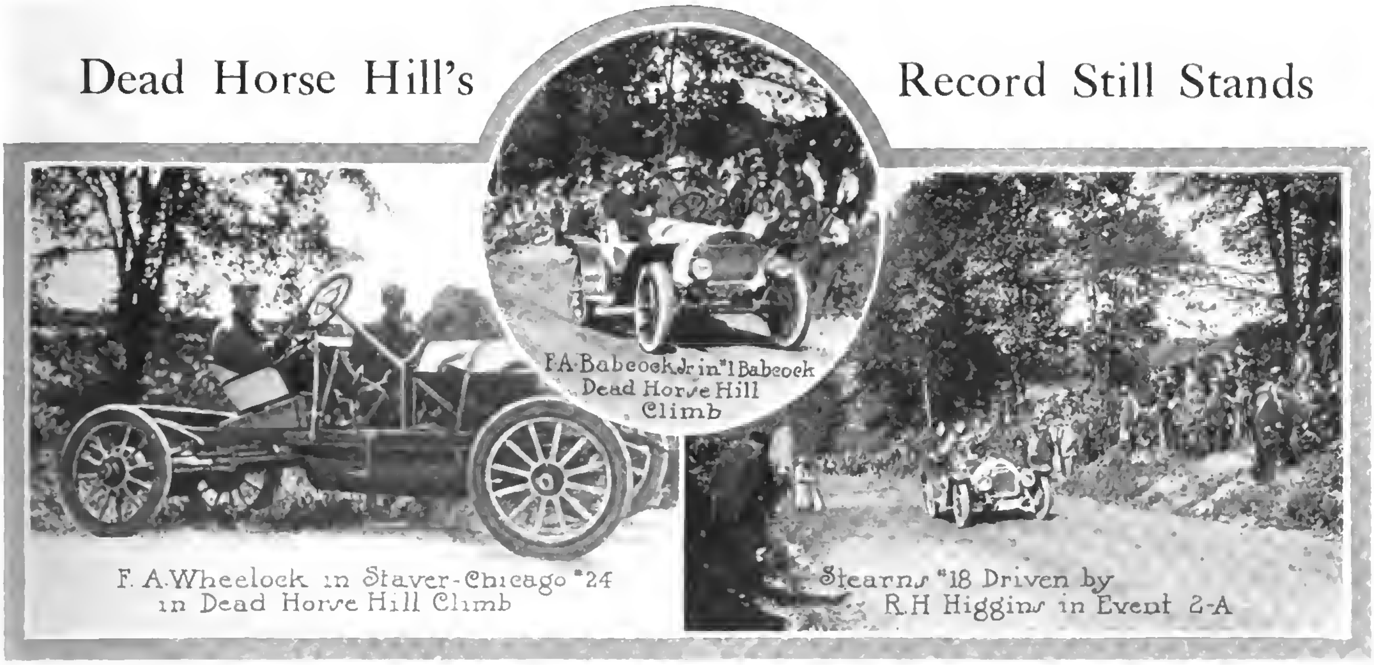
One of the effective things about the affair was the interest displayed in it on the part of the public. Everywhere along the route of the procession, crowds gathered and watched the progress of the cars and cheered the little ones heartily. The parade was for their benefit and it was given by motordom of New York and when these two phases of the idea became connected in the minds of the interested public, the result was a long series of smiles. It was freely estimated that the automobile was brought into close touch with thousands of persons during the parade whose idea of the motor car was something hostile to safety and well-being. After seeing the thousands of happy children, whose day of pleasure had been given them through the instrumentality of automobile owners, even the most prejudiced among the observers, at least had good grounds upon which to found a more charitable attitude of mind.

Splendid Line of Automobiles Waiting for the Many "Fares"

It is doubtful if any similar affair was ever carried out with the same amount of careful adherence to pre-arranged rules. Everything worked out with mechanical precision from the start, clear through the long program, to the safe return of the children to the institutions.

The affair was a notable success from every viewpoint, and plans for next years are already being discussed.

Dead Horse Hill's Record Still Stands



LEFT—Winner of event 12B. CENTER—The only electric that contested. RIGHT—Stearns had a walkover in second event

WORCESTER, MASS., June 6—Records were made in the fifth annual hill climb held on Dead Horse Hill Saturday afternoon, under the auspices of the Worcester Automobile Club, among which were three in events under the price classification, three in the piston displacement classes and the Worcester County amateur championship event. In the free-for-all contest, however, the performance of the Stanley steamer last fall stands as the record of the hill.

While the fields were small in all the events, the racing was spirited and spectacular and Worcester took an afternoon off and attended the affair in force to enjoy the sport. The hill, which has always been known as a killer of horses, is a mile long, rising 325 feet in a series of short, sharp jumps. It had been put in excellent shape for the racing with the idea of setting a new mark for the hill, but Caleb S. Bragg's Fiat Special was unequal to the task of bettering the former record.

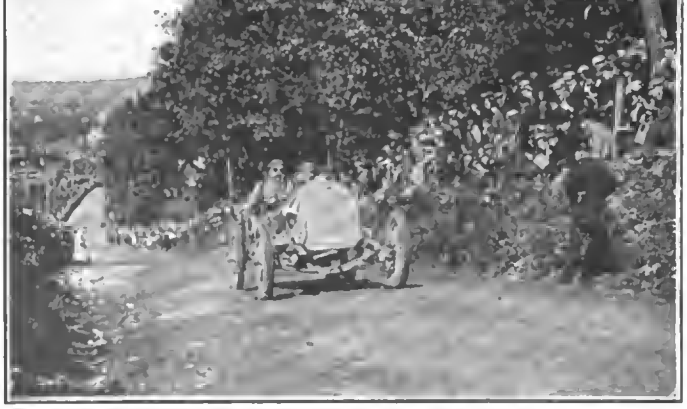
The Staver-Chicago car, entered in Event 12B, for cars with piston displacement of from 161 to 230 cubic inches, a newcomer in this section, won the first honors in competition with three others. The car demonstrated excellent speed and hill-climbing qualities and was well handled by F. A. Wheelock. In this event the Cole "30" was second, close to the winner; the Maxwell entry and the Lancia were unplaced. The winner set a new mark for its class.

The showing of the Jackson entries was prominent, winning Events 4A and 14B and finishing third in the free-for-all and lowering the record for cars of 301 to 450 cubic inches displacement and also for those listed at from $1,600 to $3,000.

The little Cameron beat the former mark for cars of its class selling between $801 and $1,200, and the Thomas made a new record for those listed at from $1,600 to $2,000.

The Stearns entry negotiated the hill with a full complement of passengers, but was not forced to high speed, as it had no opposition in the only event in which it competed.

The Stanley steamer in the Worcester County amateur championship event, and driven by its owner, Jay Clark, Jr., won the race in 1:09 9-10, giving Mr. Clark ownership of a handsome trophy, he having won two legs in the two preceding years.



Jackson Won Two Events on This Occasion

One of the most interesting performances of the afternoon was that of the Babcock Electric, which covered the route at a twenty-mile-an-hour gait, taking the hills without making any fuss. This event was carded as Number 21, and the electric was the only starter. Its time was 3.00 9-10.

The Alco won Event 15B without opposition; Event 18, one of the free-for-all affairs, and was second in the Record of the Hill event. It was also second in the main free-for-all. The car set a new mark for the 451 to 600 cubic inches displacement class.

In no less than six of the events there was but one entrant—the Thomas Flyer, in Event 1A, the Stearns in 2A, the Atlas in 3A, the Cameron in 7A, the Alco in 15B, and the Babcock Electric in Event 21 all having walkovers.

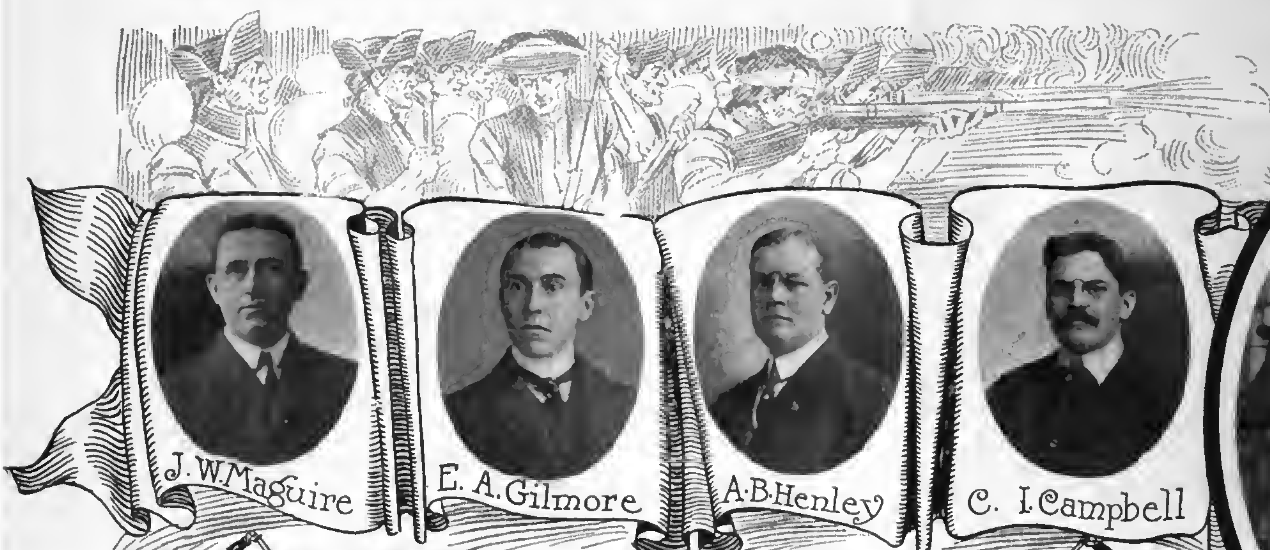
There were several motorcycle events carded, the best showing in which was made by B. A. Swenson (Indian), who made 1.03, and Edward Jerome, on a similar machine, who made 1.10 7-10.

The contest was under the direction of John P. Coghlin, former president of the club, who acted as chairman of the committee on arrangements, assisted by George D. Webb, Albert H. Inman, Daniel F. Gay and Milton C. Snyder. C. Howard Gillette, president of the Automobile Club of Hartford, was referee, and L. R. Speare was honorary referee.

The judges included the following, several of whom are presidents of outside automobile clubs: A. D. Converse, H. R. Burbeck, A. E. Bliss, A. E. Lerche, F. S. Matthewson, W. A. Thibodeau, J. Fortescue, W. H. Chase, Ira C. Coombs, John O. Heinze, A. G. Pattison, F. M. Barber and Chester I. Campbell.

The timing was under the direction of David L. Gallup. Fred J. Wagner started the cars and Charles F. Webb was clerk of the course. The scoring was done by Frank L. Coes.

The officers of the Wor- (*Continued on page* 1066.)



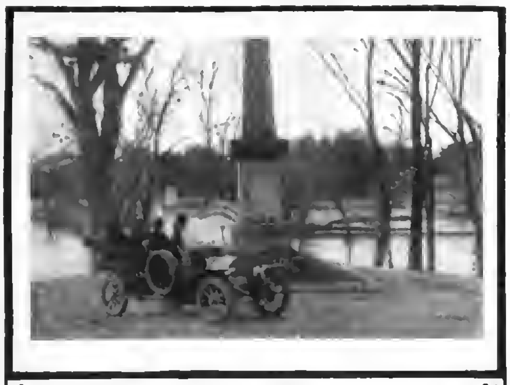
Harvard

Bay State

DURING the few years that represent the period of the automobile, Boston has progressed and developed along all lines of human advancement at a much higher rate than it achieved in any period of similar length in its history. Despite all her historic mile-posts in the record of the nation, the modern progress of Boston is her chiefest civic jewel. There has been a metamorphosis worked into the life of The Hub during the past ten years and to an appreciable extent it has been due to the automobile.

Boston is not pre eminent in the manufacture of motor cars, but it possesses all the potential factors that go to make up a rich field for their use. It is a wealthy, industrious city which boasts of its advanced thought, culture and education; so when the vogue of the motor came about, Boston at first accepted it and then made it its own.

Foremost among the expressions of motordom in Boston is the Bay State Automobile Association. This organization throughout its history of over five years has been one of the potent forces of the sport, industry and social influence of the motor car. It has been high in the councils of the city, state and nation, and no body of motorists in the land has had more to do with shaping the popularization of the American motor car than the Bay State Automobile Association.



Concord Bridge

The association has been effectively active in doing things that tended to increase the interest in motoring in New England. To no small extent it has worked to make the Boston Automobile Show one of the largest and most important functions of motordom. The Boston show ranks with those of New York and Chicago, as a result of this industrious interest.

The Bay State was one of the first organizations to take up the matter of endurance runs on such a basis as to make them valuable as tests and examples of automobile efficiency and reliability. It inaugurated the famous "Climb to the Clouds" up the rocky sides of Mt. Washington, as a club event, and the existing record for the climb is held by a Boston man, William Hilliard. Charles J. Glidden, founder of the Glidden Tour, is a member of the association and the first few events held under that title included Boston in their itineraries. Summer and winter at the earliest period of the endurance run, the Bay State conducted such competitions. As examples of its enterprise in this direction, the fact may be noted that one of the early runs of the association was to Keene, N. H., and return, and another was to Providence, Worcester and back to Boston in the dead of winter. The last contest of this sort that was held by the association was the famous run to Bretton Woods in the White Mountains, some 400 miles long. Six cars finished the run with perfect scores and in order to gain a definite result, the officials ordered the contestants to continue night and day in an effort to break the tie. Physical limitations of men and cars finally brought the run to a close.

The international mile championship trophy, offered by Sir Thomas Dewar was won first by Louis S. Ross and later was captured by Fred Marriott, in one of the steam cars manufactured by the Stanley concern. Mr. Stanley is a member of the club. Numerous speedy drivers have been developed by the Bay State, including: Herbert L. Bowden, Harry Grant, who won a Vanderbilt Cup, Joe Matson and Joe Downey.

Old North Bridge Battle Ground

The association was formed Jan. 7, 1905. L. R. Speare was chosen president. Headquarters were secured at the Hotel Lenox and later the club home was removed to Auburndale. It was found that this location was too far away from the center of the city and the club moved back to town, where a house was leased in Dartmouth Street. After two years in this convenient but expensive location, the club gave it up and took rooms at the Hotel Carleton, where it now is.

Like every other organization that has a real mission, the life of the Bay State Automobile Association has been varied. During its first three years it gained in membership and importance. Then came a split that for a time threatened the life of the body and resulted in a reorganization. This period of trouble happily has been passed and with renewed vitality, the club is reaching out into extended fields. It was the precursor of the

Where Paul R

Automobile Association

iversity

Massachusetts State Automobile Association, which is one of the main factors in the state in the way of legislation touching the motor car.

The Boston Chronograph Club is another child of the Bay State. This organization of expert timers and scorers furnished the timers for the first of the Vanderbilt Cup races and also for the early race meets on the Florida beaches. All the members of the Chronograph Club belong to the Bay State.

In the way of legislation of a reasonable character affecting motoring, the club has always been active and efficient.

Excessive liabilities caused radical action to be taken at the commencement of the current year. Instead of electing officers as heretofore, the club voted to place its affairs in the hands of a commission composed of L. R. Speare. J. H. MacAlman, E. A. Gilmore, J. S. Hathaway, A. B. Henley, J. W. Maguire, C. I. Campbell and Harry Knights. Each member of the commission is identified with some branch of motoring in an intimate way and under the present administration, the affairs of the club have been straightened out until its future has assumed the rosy hue of hope

The commission first got rid of an expensive lease that hung over the situation like a cloud and since than, by tactful and energetic effort, the membership roster has been swelled until, at present, the condition of the organization is sound and live interest in it has been stimulated.

Washington Oak

In the near future, a meeting undoubtedly will be called to elect officers and once more the Bay State will assume the usual form of an automobile club. This may not take place until the first of next year, but the solvency of the organization has been amply demonstrated.

The fundamental purpose of the Bay State Automobile Association is the welfare of motoring. Chief among the necessary elements to make motoring possible are good roads, and consequently, the best effort of the club has always been exerted toward improving the highways. In doing what it has done, it has been aided in large measure by the liberal understanding of the foundation principle of good roads by the agricultural element of the state.

James J. Hill, one of the constructive financial giants of the age in a recent statement touching on the high cost of living said that there had been a revolt against working on the farm because of its inaccessibility. He pointed out that high prices of farm products resulted through the action of the law of supply and demand and cautioned the world that the best way to reduce prices was through an increase in supply. In order to increase the supply of farm products it is necessary to make the farms accessible and thus make them attractive to the workers. Prices had advanced 100 per cent in a dozen years and the motive for radical action was very definitely present.

The answer to the problem is simply—good roads and adequate transportation. If the farmer and his wife and family and servants were placed within easy distance of the life, gayety and activity of the city; if it were possible for him to send in his produce quickly, economically and certainly to a broad, living market and to maintain close touch with the world while operating his farm, the result would be unquestionably to make farming more attractive and more profitable. The actual cost of hauling heavy loads over bad roads had eaten up the profits of many a skilful farmer and he was constantly face to face with the question of margin on the wrong side of the book. Then came the motor car; first as the plaything of the rich; then the more generally used pleasure conveyance of the moderately wealthy, and now as a most vital element of commerce

Ride was Stopped

The Minute Man at Concord, Mass.

Massachusetts was among the first of the states to realize the possibilities of good roads. The market gardeners of the Bay State had appreciated their worth early in the epoch of the automobile, and as a result the road situation of the state makes an extraordinary good example of the progress that has been achieved along that line.

How entirely justified their attitude is may be realized from the consideration of the figures that have been given.

Some Requirements of Automobile Gasoline

SENSATIONAL statements, which had for their purport the possible scarcity of gasoline, were made and reiterated with such vehemence a year or two ago, that autoists were constrained to believe that the fuel problem would become the most serious phase of the whole autoing situation within a short time. It was then believed that hexane was the only suitable distillate of the hydrocarbon series which would properly serve in automobile work, which belief was based upon the fact that the volatility of hexane was at the right rate and with sufficient uniformity to serve for the purpose without leaving a residuum.

At that time, there were many geniuses who labored under the false impression that kerosene oil would become the ultimate fuel, and that some different kind of a motor would have to be designed to burn it. Skill always comes to the rescue of the man who nurses a bugbear, and this case proved to be no exception to the rule. Instead of designing a freak motor to burn kerosene oil, it was found to be feasible to design the fuel so that it would burn in an automobile motor, and at the same time avoid having to use the distillate hexane as the sole product, at the cost of an enormous quantity of by-product, which could not be used as rapidly as produced in other arts and industries.

The distillers of oil realizing fully that hydrocarbon by-products, unless they can be utilized in the arts and industries, introduce a formidable problem, due to the fact that these by-products cannot be disposed of in any way, excepting industrially. Were they to be run into a sewer they would reach the waterways, float on the top, and become a menace; likewise to spill them into a depression in the earth, would be to make an artificial liquid hydrocarbon lake which would be a menace also. Enough has been said to indicate that the by-products of the distilling process in the making of automobile gasoline must be regulated to the quantities which will find a use in various ways. When the seriousness of the problem was fully realized, the experts who deal with such matters began experimenting with composite fuel, with the idea of utilizing the entire range of the distilling process, including hexane, heptane, octane, and decane, with perhaps other fractions, should the plan prove efficacious.

It was not necessary to involve the pentane fractions, they being more volatile than hexane, for the reason that these lighter distillates are vastly in the minority and have many uses, so that they may be readily disposed of in the ordinary way. It is fortunate for the automobile situation that the lighter distillates are not so good as automobile fuel; the heat units per unit of weight are less, and the inflammability is in excess of that desired, not only from the point of view of safety, but for the further reason that the rate of flame travel in the compressed mixture in the combustion chambers of cylinders, is in excess of the actual demand, and motors so provided would be prone to knock.

As carbureters were improved, and as automobile engineers arrived on a better basis in their understanding of the requirements, it became apparent to them that there should be a sufficient quantity of the lighter distillates present in the total fuel to permit of starting a cold motor without having to crank, beyond the mere spinning of the motor, as an outside limit. Automobile fuel, to satisfy this phase of the situation, must hold enough hexane to serve as the volatile member of the family, after which it may be diluted with the heavier distillates, even beyond the point marked decane.

Bosch Dual Ignition System Explained

STABILITY of ignition for motors, considering the nature of the service and exposure to the inclemency of weather and lack of attention, or what is more to the point, the kind of attention which emanates from the curiously inclined, is of prime necessity. Realizing this, the Bosch Magneto Co., headquartering in New York City, brought out what is known as the dual system of ignition, which, in addition to a magneto, involves the use of a battery, instead of the employment of a separate times and a multi-coil, though the magneto is so contrived that a suitable interrupter is incorporated into the mechanism and a form of step-up transformer is made to do double duty, serving primarily to spark the latent charge in a cylinder in the act of starting the motor from the seat, and in case the magneto should become deranged the same coil may be brought into play to serve as a substitute sparking system.

The magneto is installed in the usual way, and although the wiring and connections are different, as will be shown, even so the problem is bereft of complexity, and a so-called clean dash is one of the advantages realized. The unit coil, which is of a shape to fit snugly in a circular housing of metal, is so encased as to be water-tight, and the condenser, trembler and switch are included within the housing.

Switch Handy to Get At

The switch is so made and connected as to enable the operator of the car to switch from the magneto to the coil and vice versa at will, and a neutral point intervenes so that the electrical system may be turned off when the occasion requires.

The dual system magneto differs from all others of the same make in that a battery interrupter is added and the connections are altered to suit the occasion.

Neglecting the parts which are required to compose a complete and perfect mechanism, it remains to be observed that there are two separate sets of contacts, each perfectly independent of the other, and either set may be used without the other; nor does it matter if one is out of order—the other will work perfectly in the meantime. The battery contact system, used to interrupt the current flowing from the battery, is just as

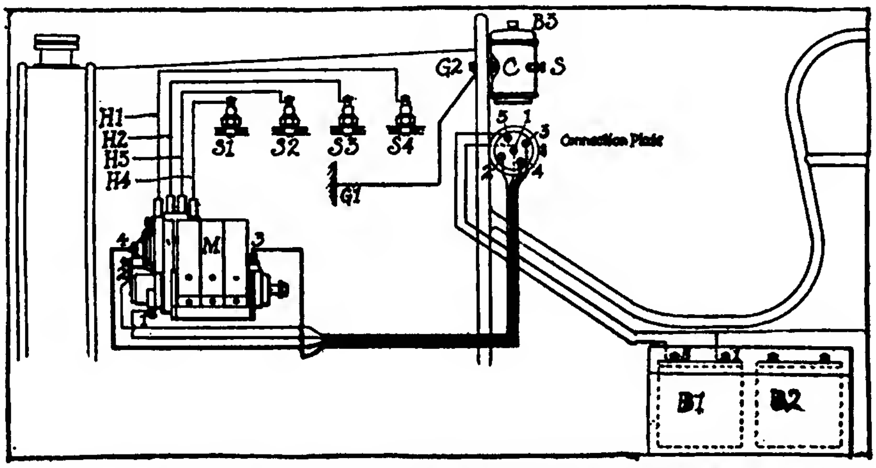


Fig. 1—Diagram of wiring of the Bosch dual ignition system, showing the magneto, spark plugs, dash coil, wiring connections and battery

capable and quite as independent as here arranged as it would be in a separate housing, but it offers the inducement of being in a place of natural advantage and reduces the wiring system to its simplest form.

Diagram of Bosch Dual Wiring System

For a four-cylinder motor the diagram as presented in Fig. 1 will serve the purpose here, although it will be understood that any motor, with any number of cylinders, as usually employed, may be adapted. This system will suffice for ignition purposes. The magneto M is placed at any convenient point, and high tension leads H1, H2, H3 and H4 may be connected to the four spark plugs S1, S2, S3 and S4. In these respects the dual system is no different from the conventional forms of high-tension magnetos.

Back of the high-tension leads, as they pass from the magneto to the spark plugs, the system takes on a dual character, and the connections between the coil C, on the dashboard, the magneto M, and the battery B1 or B2, if a reserve battery is available, should be from No. 1 on the magneto and No. 1 on the battery to No. 1 on the connection plate of the coil C, which is given diagrammatically just below. Nos. 2, 3 and 4 from the magneto should connect to corresponding numbers on the connection plate of the coil, and No. 5 of the battery should lead to No. 5 of the connection plate of the coil. The ground connection G1 to G2 completes the circuit. The connections to the control, which is a switch S, are made when the system is assembled, and in starting all that can be done is to press the button B3 on the top of the coil, when, if the conditions are right in the cylinders, as respects mixture, the motor should start.

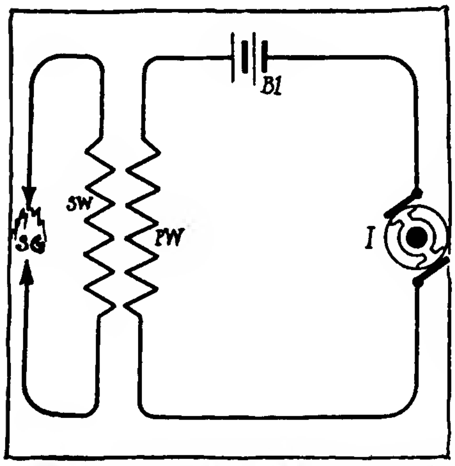

Fig. 2—Theoretical diagram of the dash spark coil, showing the windings of the coil as saw-teeth, spark gap, battery and interrupter

It is generally well understood that a static transformer will not set up an inductive secondary electromotive force when a continuous current is applied to the primary windings of the transformer, and this system mystifies many motorists because they do not understand that static transformers are usually designed for alternating current work, and they do not see wherein the difference lies or why this particular transformer will work and others will not.

There are one or two little details that stand in the way of a perfectly clear understanding of this situation, and those who understand that a coil with a trembler will deliver a spark have only to remember that the Bosch coil, as used in the dual system, is a trembler coil when the button is pressed, and a step-up transformer at all other times. As a step-up transformer it receives its intermittent current in the primary winding, from the battery, to be sure, but the system of wiring is so contrived that the battery current is interrupted by the battery interrupter.

Utility in Sparking

An intermittent current, while it will not deliver a secondary electromotive force holding to the sine form of wave, will, nevertheless, induce a secondary electromotive force that will serve for sparking, when the primary current is so impressed. This is what happens when the battery is cut in by the switch S, Fig. 1, and the system gives one spark per interruption, which is all that is required in ignition work, provided the spark is rightly timed and of sufficient voltage and energy.

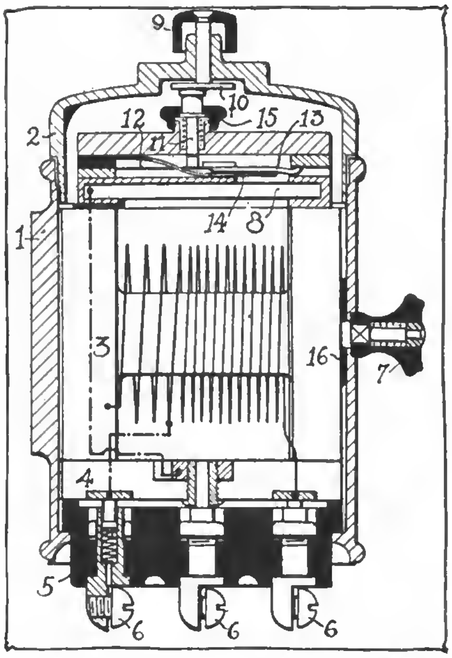

Fig. 3—Section of the dash coil, presenting connections at bottom, magnetic core within with windings thereon, and trembler at top, all within a waterproof case

Fig. 2 is a diagram of the system, in a characteristic way, in which B1 is the battery, I is the interrupter, PW is the primary winding of the transformer, SW is the secondary winding of the transformer, and SG is the spark gap. In the Bosch dual system, I is located in the magneto for convenience, PW and SW are combined in the coil C, Fig. 1, and the gap SG represents one of the spark plugs S1, S2, S3 and S4, Fig. 1.

The practical way in which the scheme is carried out is best shown in Fig. 3 of the Bosch coil in section, which, together with the explanations, affords all the information that can be of any value in view of what has been said. In this illustration, 1 is the cylindrical housing for the coil with its cover cap 2. Within the housing is the soft iron core 3, around which the winding is placed, as shown. The condenser 8 works in connection with the coil. S7 is the switch handle, which protrudes from the coil. Four is the connection plate at the base with which the connections 6 attach. The vibrator parts are shown in the top, 9 marking the press button, 12 the vibrator spring, and 11 the pin for setting the vibrator working. Fig. 4 represents the completed coil in its housing, with the control switch facing the driver. The system is widely used, it offers the advantage of a double ignition, having all the virtues of two independent methods, and the magneto is unincumbered by any part which can be construed as likely to complicate it in any way. The battery is regular, placed as in ordinary system, and starting on the spark, insofar as this plan is possible, is advisable and easily managed due to provision which is made for it. The system offers not the slightest chance for a tinker and an unlicensed screwdriver.

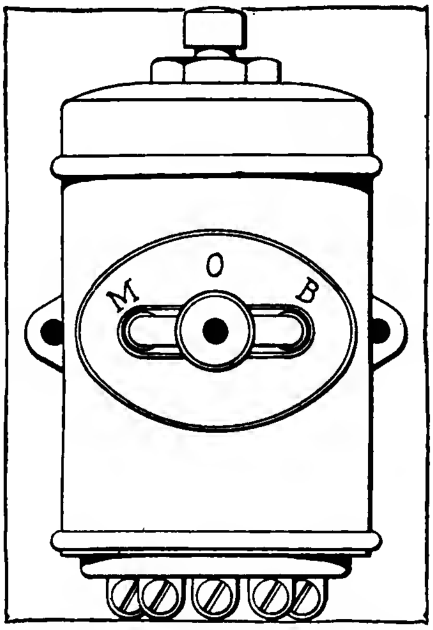

Fig. 4—General appearance of the dash coil, presenting means of opening the top for purposes of inspection and the switch on front for use in turning the magneto, or coil on, also for throwing to neutral or open.

Engineering Digest

A carefully abstracted digest of accounts of engineering activities as they are reported in society transactions and technical papers throughout the world.

Study of Concentric Valves.—Concentric valves properly constructed constitute a progress in motor design, according to F. Carlès in *La Vie Automobile* for May 14, and the more general adoption of this type would be desirable, if the elimination of all valves were not more desirable yet. One of the principal advantages of the concentric double valve is the following. The fresh gas, usually at a temperature slightly above that of the surrounding atmosphere, in passing by the exhaust valve contributes to keeping it cool, and the concentric arrangement of the parts obviates that unequal expansion and contraction of parts which sometimes leads to seizures in motors with two distinct valves. The concentric valve permits the designer to give his combustion chamber a cylindrical or even a hemispherical shape, which heats less than the ordinary. But there are also disadvantages. As the gas cools the exhaust pipe it is itself heated and expanded. Figuring it out, one finds that the mixture may readily be raised a hundred degrees in temperature, whereby its weight, and therefore the power of the motor, may be reduced 30 per cent. Also, the weight of the movable parts of the exhaust valve, especially those which are bell shaped, is increased, requiring stronger springs, which wear and strain the cams and rollers. Finally, the concentric valve is expensive. In the Pipe, Fig. 3, the bell shaped exhaust valve is machined from a block of special steel, in order to make it light, but the cost in tool wear alone is considerable. The foregoing leads to the inference that concentric valves are best adapted for a motor in which they may be cooled by water rather than by the explosive mixture. They then offer the advantages of equable expansion and contraction of parts and an opportunity for a hemispherical combustion chamber, without any accompanying drawbacks.

Fig. 1 shows the Esnault-Pelterie valve, used in an aviation motor. The two valves are in one piece, the exhaust valve forming a slide. Both are operated by the same rocker arm. Here lies trouble. At the end of the explosion stroke orifices EE are uncovered and AA covered by the slide. When now comes the time for admission of gas, the valve descends a little more, but for an instant the two orifices are uncovered simultaneously, and there is suction through the exhaust valve. When the valve is closed again the same thing happens once more. Another inconvenience. Suppose the valve is depressed five millimeters for the exhaust; it must then go down still a little further in order to begin to uncover the intake, say two millimeters, and thereafter still farther, say six or seven millimeters, to complete the uncovering of the intake and covering the exhaust orifice. That makes, then, at least 12 or 13 millimeters stroke for the valve stem, even with as scant an allowance for the diameter of the orifices as five millimeters.

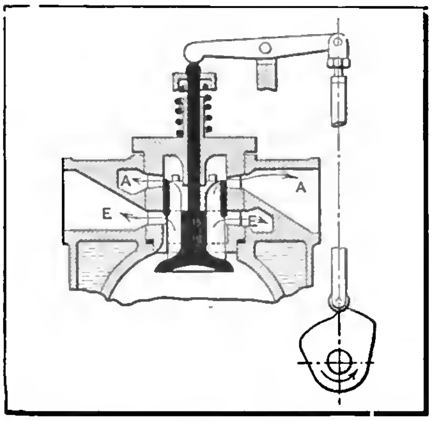

Fig. 1—Esnault-Pelterie valve in position as between exhaust and induction

In the Vorreiter valve, from Austria, Fig. 2, the slide is not integral with the central valve, but abuts against it by means of springs. The two valves are depressed together to permit the exhaust to escape. Continuing to descend the slide valve T reaches a conical seat, and both valve openings are closed. Then the central valve continues to descend, and the admission passages are opened to fresh gas. This arrangement may be suitable for large valves, but if the slide should stick, even slightly, it will no longer follow the intended movements, and in that case the motor will be stalled. The little spring cannot be very strong because it would compensate against the main valve spring (says the author). Also, the multiple conical seats do not appeal to the mechanical sense, and the guidance of the valve and of the slide seems insufficient, judging from the illustration. The total lift must be even higher than in the Esnault-Pelterie valve. Nevertheless, Mr. Vorreiter states that he has obtained a higher thermic efficiency with this valve applied to small motorcycle motors than with separate valves and a 2 per cent. higher utilization of dimensions, but the latter result may be due solely to the improved form of the compression chamber.

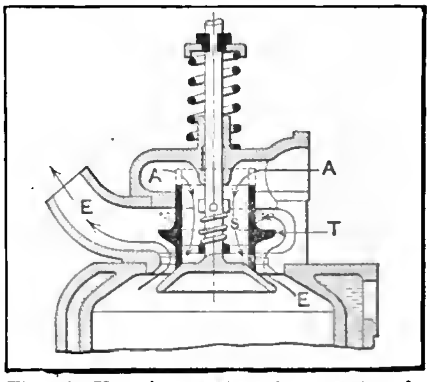

Fig. 2—Vorreiter valve in position for exhaust

The maximum valve lift is normal in the Pipe construction, Fig. 3, as each valve is operated separately, and the guidance is perfect, the induction valve sliding in the exhaust valve and the latter in its seat. In order to leave the slide free to expand and prevent the exhaust gases from entering the admission piping, the slide is provided with a segment upon its upper portion. Two rocker arms are used, A_1 and E_1, that for the exhaust valve being forked, and two tappets, two cams. This complication has perhaps no other advantage than the easier design and adjustment of the cams, but the Pipe system generally carries with it great facility in dismounting the two valves. The seat is screwed into the cylinder head and secures thereby an aluminum valve chamber which carries the induction and exhaust pipes. This valve chamber or box is in common for two cylinders, and remains in place if the valves of only one cylinder are dismounted.

The Panhard-Levassor valve, as applied to aviation motors (for example, in the Tellier aeroplane, which recently flew over Paris), is also designed on the principle of separate functioning

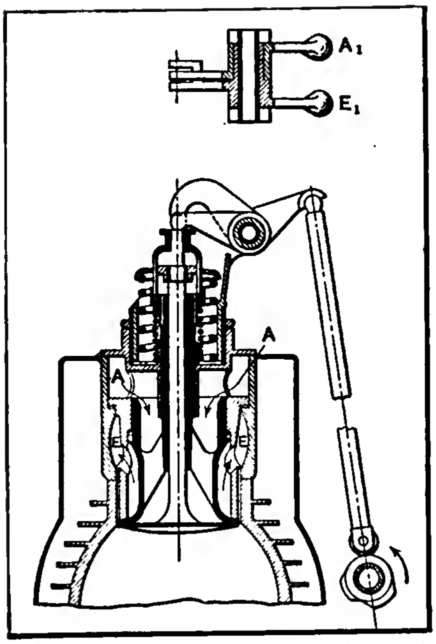

Fig. 3—Pipe valve in position as during explosion stroke

for the two valve members, and has the advantage of normal lift and large apertures for both admission and exhaust, as well as guidance of the slide direct in the seat. It is operated by a single tappet rod, which works by compression for the exhaust and by traction for the admission, see Fig. 4. The rocker arm is forked, and presses on the cover for the upper part of the valve slide, upon which is mounted the small rocker arm *C*. When the tappet descends, the rocker arm, being raised, comes in contact with the small rocker arm which depresses and opens the admission valve. In this movement the tappet and the roller are held down upon the cam by the spring *r*. The exhaust is water jacketed on all sides and the fresh gas is not required to cool the valve seat and is therefore not expanded unduly.

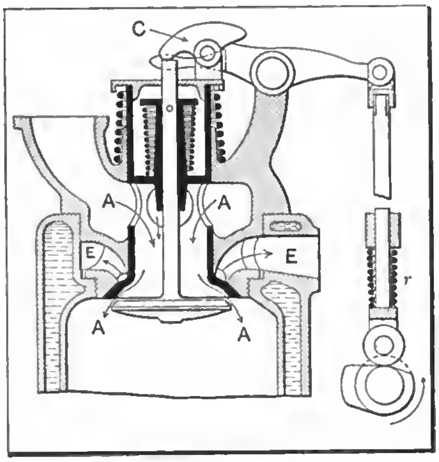

Fig. 4—Valve of P-L aviation motor, in position for admission of gas

In the Miesse valve the exhaust takes place through the center and the admission at the periphery. A single tappet and rocker-arm control the valves, and the lift is considerable. To effect the exhaust the rocker arm presses upon the central valve; this begins to descend allowing the gas to escape by the way of the interior of the bell, until the cap *c*, integral with the central valve, begins to impinge against the bell, thereby closing the aperture for the gas escape. Continuing to descend the central valve carries the bell with it and opens the passage for the fresh charge. The principal objection seems to be that the central valve is never cooled, while the fresh gas enters the cylinder heated, reducing the power of the engine.

Three samples of titanium steel, Siemens-Martin basic process, were obtained at the Osnabrück steel works by running one-half of each of three melts into a ladle, while at the same time adding metallic titanium. The other half of each melt was poured unalloyed (at the same time?). In this way three comparable pairs of ingots, each of more than one ton, were secured, the titanium running 0.038 per cent. in one sample, 0.092 in another and 0.14 in the third. There was no difficulty in getting a mixture in the ladle, and the samples all rolled perfectly sound. Large and small billets were made from the alloyed as well as from the corresponding unalloyed ingots, and from these billets test pieces were rolled and forged. Tensile tests showed greater ultimate strength for the titanium steel than for the corresponding plain steel, the difference being much more pronounced in rolled test pieces than in forged ones, however. By far the most important superiority was in toughness under drop-hammer test. The annealed titanium steel endured four times as violent impacts, in the sample with least titanium, as the plain steel. The composition of the samples was as follows:

	C.	Mn.	Si.	Ph.
I.—Without titanium	.385	1.00	.22	.44
With titanium	.37	1.00	.23	.049
II.—Without titanium	.52	1.36	.22	.078
With titanium	.54	1.33	.32	.07
III.—Without titanium	.48	1.17	.20	.075
With titanium	.48	1.17	.21	.075

The titanium left in the finished metal tested out only from 0.02 per cent. to 0.04 per cent., indicating that its function had been scavenging, taking oxides and possibly nitrogen from the metal. The toughness imparted to high-carbon steel was especially remarkable and in the bending tests the high-carbon sample, containing .52 C., could be bent further than its mate. Fractures of the titanum steel, even of sample I, with only .038 per cent. of titanium added in the ladle, showed a fibrous character similar to that of wrought iron, while fractures of the plain steel were granular. The author calls attention to good results obtained in another case at a crucible steel works by adding aluminum shavings to a strong titanum alloy, before pouring, and to the favorable reports received from the United States, where considerable quantities of titanium steel for rails have been made by adding ferro-titanium in the electric furnace, and where the material has been found superior for rails in wearing qualities and resistance to abrasion.—*Stahl und Eisen*, April 20.

Students of aeronautics may be interested in a new work, 990 pages, "Le Navire Aérien," by L. Marchis, who was recently appointed professor of aviation at the Sorbonne University in Paris. Commandant Voyer, reviewing the work in *Revue Générale des Sciences* for May 15, says it is the most complete in existence, yet the chapter on propellers is lacking, the author awaiting developments on this point.

Metallic, especially aluminum, coatings may be applied by means of steam or gases through a pneumatic nozzle to practically any object or surface. Though the metal must be molten, the metal-laden mist thrown out with great velocity from the nozzle is so thoroughly cooled, through the low temperature of the released gases, that it reaches the object to be coated at temperatures ranging from 10 to 60 deg. C. The process takes the place of galvanizing or tinning and requires no conductivity of the surfaces, or ability to resist heat or water. The coating can be made of any thickness. Steam, if used, must be superheated. The best gas for coating metals liable to oxidation is nitrogen. Hydrogen can also be used. The applications to the automobile industry are obvious, including also the use for patterns, by coating those made of cardboard or wood. (The principle is similar to that used in the improvement of old roads by driving tar into the stone surfaces by air pressure, and recently experiments have been made in New York City with rapid plastering of concrete walls by the same method.) Presented by U. Schoop to the *Académie des Sciences*.—*Comptes Rendus* for April 25.

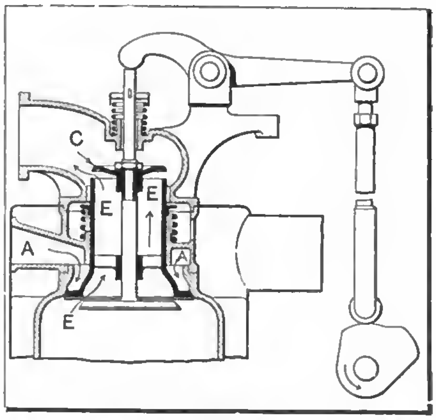

Fig. 5—Miesse valve in position for exhaust

Questions That Arise

A Series of practical questions relating to the automobile, its parts, and their functions, which arise upon various occasions, together with easily understood answers to the same.

[60]—What is the coefficient of friction?

It is the ratio of the force required to slide a body along a horizontal plane surface to the weight of the body. It is equivalent to the tangent of the angle of repose, which is the angle of inclination to the horizontal of an incline plane on which the body will just overcome its tendency to slide. The angle is usually designated as θ and the coefficient by f. The customary equation for the coefficient of friction is expressed thus:

$$f = \tan \theta.$$

[61]—Why is there a difference in voltage between charging and discharging a battery?

The chemical reactions during charging are not the same as when the discharging is being done. To obtain the same result it is necessary to maintain the same reaction.

[62]—What is the difference in voltage between charging and discharging of a battery?

According to Prof. Ayrton (Jour. Inst. Elec. Eng., England, Vol. 19, p. 699), the charging voltage during the first two-thirds of the charge is about 0.14 volt higher than the voltage on discharge over the same range. Beyond this point, in the charging period, the difference continually increases. The increase in voltage during charging, over that for discharging, is more than that due to internal resistance of the battery.

[63]—What is the greatest influence for excessive increase in voltage during charging over the voltage realized on discharging?

That it is undesirable to realize a great difference in voltage during charging of a battery over the voltage available during the discharging period is true, and, from the most authentic accounts, it is believed that a condition of persistent sulphation is at the seat of the trouble.

[64]—What is the cause of this persistent state of sulphation?

Allowing a battery to stand in the discharged state; to avoid this state of sulphation it is necessary to charge the battery immediately after it is discharged.

[65]—Will a battery continue to self-discharge after it is partially discharged?

The presence of any lead sulphate at all is enough to induce a condition of "local action," and self-discharging, so called, is but a sign of local action. Sulphate of lead is formed when a battery is in process of discharge, and if any discharging is done at all there will be some sulphate present, so that local action will be induced if a battery is allowed to stand after it is put on discharge. The one way to avoid trouble of this sort is to keep every cell of the battery in good working order and fully charged. A fully charged battery is substantially free from lead sulphate.

[66]—What is the underlying theory of the formation of sulphate of lead in a storage battery of the lead type?

During discharge, the electrodes are reduced to lead sulphate, with the delivery of sulphion from the electrolyte. A general expression of the chemical reactions (not counting divers intermediate reactions) may be taken as follows, according to the accepted idea of storage battery engineers:

$$PbO_2 + 2H_2SO_4 + Pb = PbSO_4 + 2H_2O + PbSO_4$$

This expression includes the combined reactions in the positive and negative electrodes of the cells of battery. They may be separated out in the manner as follows:

Reaction for the positive plates:

$$PbO_2 + H_2SO_4 = PbSO_4 + H_2O + O$$

Reaction for the negative plates:

$$Pb + O + H_2SO_4 = PbSO_4 + H_2O$$

[67]—What is the difference between normal and persistent sulphation in a battery?

Under normal conditions of discharge, it is claimed that the sulphate formation is on the surface of the "active material" and to a certain depth therein. If, on the other hand, the sulphate is allowed to accumulate beyond a certain point, it will ultimately penetrate to the supporting grids. After this condition is established, it is difficult, if not impossible, to realize any further good from the sulphated cell of battery; the sulphate is of high electrical resistance, and its presence between the active material and the supporting grid prevents the formation of the character of active material which obtains when the battery is in a state of proper charge. In addition to this, the sulphate, being in excess, isolates all the available active material by coating over, with the result that it is beyond the reach of the charging current.

[68]—What is the best way to overcome troubles of this sort?

If it can be overcome at all, which is a question, long-continued charging at a low rate is the best course; the electrolyte must be adjusted to proper strength before this "doctoring" charge is administered. Of course it can be overcome to a certain extent; the battery may be corrected in a measure, even in the worst example. That it will ever be as good as under normal conditions, however, is a question.

[69]—Will the life of the sulphated cells of battery be impaired?

It has been found that, after a cell of battery is over-sulphated, the life is but short at best.

[70]—What is the character of the active material which abounds on positive plates of storage batteries?

When a battery is fully charged, the active material is composed of peroxide of lead, the formula of which is PbO_2.

[71]—How much of this material is needed relative to the normal output of a cell of battery?

In the first place, but a small portion of the actual quantity of peroxide of lead on the positive plates is available for use. Of the material which is available, it is claimed that it has a value of one ampere hour for 4.48 grams of material. This is the theoretical value, according to Planté. There is some question as to the accuracy of this figure; it has also been given as 4.44; the Planté valuation is the generally accepted figure.

[72]—Why is it that all of the active material may not be utilized?

Lack of porosity of the active material is one of the great reasons; the fact that the sulphate, after it penetrates to the surfaces of the supporting grids, will induce a condition of abnormal electrical resistance, and defeat charging under effective conditions, must be taken into account. Disintegration of the active material is bound to follow.

[73]—What has porosity to do with the action of a battery?

If the electrolyte cannot "soak in" to the section of the active material, there will be no action at all, for the reason that it is the sulphion in the electrolyte that aids in the formation of lead sulphate; prevent the formation of lead sulphate and the action which is at the bottom of the useful work will be prevented also.

[74]—What is electrolyte?

In a storage battery it is the solution or composition in which the elements are submerged.

[75]—Must it be in liquid form?

No. It is sometimes in jelly formation.

[76]—What is its basis?

In the lead-type of storage battery, electrolyte is made up of a certain percentage of sulphuric acid together with a certain proportion of pure water. The strength, when the battery is fully charged, is 25 degrees Baumé. If it is desired to obtain jelly-like formation, some compound is added to bring about the desired condition. It has not been found that such formations are efficacious; they do eliminate the troubles of having a liquid to deal with, but other troubles are induced, and they have to do with the life and efficiency of the battery.

[77]—What is the nature of the material such as used to solidify the electrolyte?

Silicate of soda-water glass.

[78]—Why should the electrolyte be pure?

Every reaction excepting the normal requirement is at the expense of the life and efficiency of the battery. Some foreign substances act in the capacity of forming ingredients and reduce the life of the battery at a high rate.

[79]—What are forming substances?

Any compound which will, in the presence of an electrical charge, or discharge, reduce metal lead into a salt of lead.

[80]—What has forming to do with storage batteries?

In the process of manufacture of storage batteries, it is the custom to "form" them after they are made up of the desired ingredients. In a Planté type of plate, for illustration, the active material is formed out of the lead of the plate, in the absence of any salts of lead. This forming is done by charging the plates after they are placed in a forming electrolyte. It may be a nitrate solution, or any other solution which will hasten the formation of salts of lead out of metallic lead during the passage of an electrical current through the plates, using the solution to complete the circuit and to act in conjunction with the lead to form salts of lead.

[81]—What has all this to do with the use of storage batteries?

If a battery can be formed at a rapid rate by the addition of nitrates, or other forming ingredients, during manufacture, it stands to reason that this same forming process will be present during the life of the battery in service, if only the nitrates or other forming ingredients are present in the electrolyte.

[82]—If forming ingredients are good to use during the manufacture of a battery, why are they so undesirable after the battery is put into commercial service?

In the process of manufacture, the aim is to continue the forming process until the capacity of the battery is up to the desired standard. Were the process carried on for a longer period of time, the capacity of the battery would be increased, but the life of the same would be decreased, until finally the battery would fall apart; strength of the supporting grids would be insufficient for the mechanical requirement. This same process, if it is allowed to go on after the battery is placed in service, as it would were the electrolyte to be contaminated, would add to the capacity of the battery for a time, but the life of the same would be decreased.

[83]—Which substances must be kept out of the electrolyte?

Everything but water and sulphuric acid.

[84]—How is this possible?

Use pure distilled water and chemically pure brimstone sulphur in the process of manufacture of the electrolyte; after the battery is made, avoid the contamination of the same by keeping the cells sealed and by using distilled water in making up for loss of electrolyte.

[85]—What is the reason for having to add water to the battery in service?

Evaporation of the water is bound to take place at a slow rate, and this loss must be compensated for by adding an equal amount of the same. During charge, when the battery is nearing a condition of full charge, hydrogen and oxygen will be liberated at the nodes, and these gases, as they burst free, will pick up a certain amount of liquid and "spray," which is formed, will shoot out of the cells; this spray is made up of water for the most part.

[86]—Why not prevent the spraying by sealing up the cells?

Were the cells sealed up tight enough, the formation of gas in the manner as stated would cause a gas pressure in the cells, and they would disrupt; in order to avoid the generation of a pressure, the cells are provided with a "vent" which allows the gases to escape as they are formed, but water is prevented from escaping excepting at a very slow rate; water does escape, however, and in time it must be replenished.

[87]—Why is it that water only escapes during the gassing period?

Very little of the sulphion escapes with the spray, for the reason that, during the gassing period, some of the sulphion is mingled with the active material, and the balance, being heavier than the spray, stays behind. Still, some sulphion is lost, and the time must arrive when the same should be adjusted also.

[88]—How is the correction made when the electrolyte falls below the desired strength?

Add a sufficient amount of sulphuric acid to the electrolyte to bring up the strength to the desired level.

[89]—What is the method of procedure?

One way is to draw off a certain quantity of the weak solution, after the battery is fully charged, and add enough strong solution to bring about the desired balance. The strong solution should be made for the purpose of pure ingredients, and register about 30 degrees Baumé.

[90]—Why not add pure concentrated sulphuric acid?

It is dangerous to the one who undertakes it, due to the rapid generation of heat when concentrated solutions of acids are spilled into water or weaker solutions of water and acid. The explosive effect will cause the acid to fly about, and if it contacts with the person who makes such a mistake the result may be very disastrous. If it is not proper to use concentrated solution in a cell of battery, the same objection will be present if the strong acid is used in the process of equalizing.

[91]—Why not empty out all the old acid from the cells and put in new solution of the right strength?

The elements will then be uncovered, and if it is desired to keep them submerged in electrolyte during service, the same requirement will be present during the period of equalizing.

[92]—What is the objection to uncovering the elements?

If the electrolyte is allowed to fall below the level of the active material on the elements, heat and other manifestations of a chemical change will be rendered manifest at once; the active material will harden; porosity will be reduced, and the life of the battery will be much reduced; the capacity will also fall off as the porosity is decreased.

[93]—Will the same amount of water have to be added to each cell of battery during the process of equalization?

No. The loss of electrolyte, while it goes on in each cell of the battery, will not be the same in each. In the process of equalization, there are two points to consider.

(a) Water must be added to keep the elements submerged completely.

(b) The strength of the electrolyte must be maintained equal in each cell of the battery, and, in order to do this, it is necessary to test each cell independently (when the battery is charged and at a constant temperature) and adjust the strength.

Difference Between 2-Cycle and 4-Cycle

Editor THE AUTOMOBILE:

[2,282]—As a subscriber to your valuable paper, I notice that motors are referred to at different times as 2-cycle or 4-cycle. Please advise me what a cycle is, and what is the difference between 2-cycle and 4-cycle. SUBSCRIBER.

La Fayette, Ala.

In the 4-cycle motor there is one power stroke in each four strokes; there are two strokes per revolution of the crankshaft; valves are used to regulate the inflow and exhaust. In the 2-cycle motor there is a power stroke for each two strokes, and ports as shown in Fig. 1, are so placed as to admit the mixture and permit exhaust on each down stroke of the piston. The arrows indicate the direction of flow of mixture from the crankbox and exhaust to the atmosphere. In this illustration, a fan is shown in the act of exhausting. This fan is not used in regular practice, and the exhaust takes place under terminal pressure.

How to Estimate Horsepower of a Motor

Editor THE AUTOMOBILE:

[2,283]—To estimate horsepower of a motor, I understand the process is to square the bore of the cylinders, multiply by the number of cylinders and divide by 2.5. Will you kindly explain what is meant by squaring the bore, giving an example? Also kindly show the process for determining the displacement of a motor, in cubic inches. READER.

New York City.

To square a number is to multiply it by itself, that is to say, the square of 2 is equal to $2 \times 2 = 4$, or $4 \times 4 = 16$, or $16 \times 16 = 256$. Likewise, any number multiplied by itself will give the square of that number. In using the formula, remembering that the power of a motor is in proportion to the square of the bore of the cylinder, the formula may be written as follows:

$$\text{Horsepower} = \frac{\text{bore in inches squared} \times \text{number of cylinders}}{2.5}$$

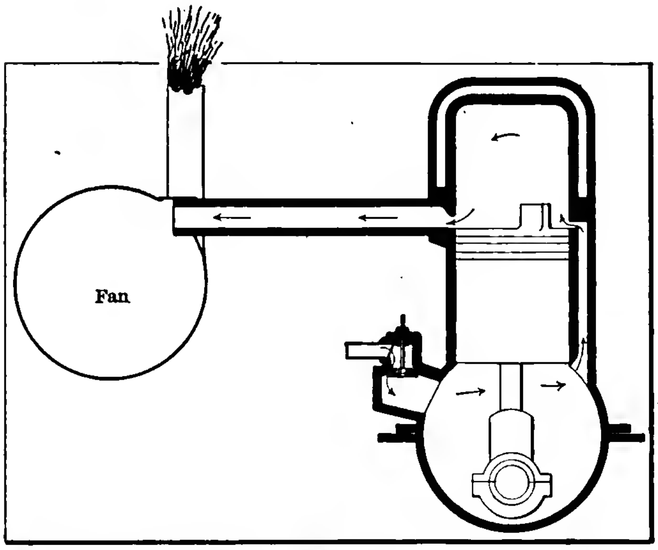

Fig. 1—Typical illustration of a 2-cycle motor with mixture in the crankbox, and an automatic admission valve thereto

For a 4-cylinder motor, if the bore is 4 inches, this formula will give:

$$\text{Horsepower} = \frac{4 \times 4 \times 4}{2.5} = 25.6$$

Using precisely the same method, the horsepower of any motor (according to this empirical formula) may be approximated.

It will be understood that this method of approximating horsepower, while it is a good one in a general way for purposes of comparison, does not give the real horsepower of the motor. The best method of determining the horsepower of a motor is to subject it to a dynamometer test.

Gasoline Is Vaporized by Heat

Editor THE AUTOMOBILE:

[2,284]—I have learned by reading THE AUTOMOBILE that gasoline will remain as a liquid until it is vaporized by the application of heat. I also understand that the reason why gasoline is suitable for use in automobile motors, aside from the fuel value it holds, is because it boils at a low temperature, thus making it unnecessary to utilize special forms of heating equipment in the process. There is one point which is a little obscure in my mind which I will bring out by asking a question. If heat must be transferred to the gasoline in order to vaporize it, is it not a fact that some of the fuel value is lost in the process? In other words, I would like to know the relation of the latent heat of evaporation, and to have you state a method by which the number of heat units involved may be ascertained. SUBSCRIBER.

Newark, N. J.

The amount of heat measured in B. T. U. necessary to raise 1 pound of gasoline 1 degree F. is 0.500 (taking an average value for the character of the gasoline used for fuel in automobile motors), and it therefore follows, as a close approximation, that a drop of 1 degree F. in the temperature of 1 pound of this gasoline corresponds to the transfer of 0.500 B. T. U. of heat. The specific heat of atmospheric air at a constant pressure is 0.2375 B. T. U. and a drop in temperature of 1 pound of air under these conditions is attended by the dissipation of 0.2375 B. T. U. of heat.

Since the best mixture of air and gasoline for automobile work is on a basis of 1:15.39 gasoline and air respectively, the transfer of heat will be as follows:

$1 \times 0.5 + 15.39 \times 0.2375 = 4.155$ B. T. U.

Considering the latent heat of evaporation of gasoline as equal to 210.5 B. T. U., it follows that 210.5 B. T. U. of heat must be supplied either by the ingredients or from some outside source before the liquid will change to gas form. In a carbureter it is necessary to consider that the heat must come from some outside source, and it is for this reason that hot-water jacketing is resorted to. In some cases the heat is supplied by heating the air before it passes to the carbureter and, while this is not the most efficacious way, even so, if the application is well made, it works very well indeed.

At all events the gasoline will not vaporize until the heat balance is established in accord with the requirement as above stated, which to bring about requires:

$$\text{Drop in temperature} = \frac{210.5}{4.155} = 50.66 \text{ degrees F. fall of}$$

temperature of the mixture to accomplish the necessary transfer of heat. Changing temperature, which is present when the fuel is being vaporized, has one other effect that interferes with good carburetion, i.e., the viscosity of the liquid changes, the difference being sufficient to cause the flow of gasoline through the nozzle to increase with temperature enough to upset the balance when the motor is running fast and in a heated condition. The effect of temperature may be stated as follows:

Temperature, °F..........	50	59	68	77	86	95
Weight of gasoline........	1	1.073	1.145	1.212	1.260	1.335

The difference, as given, is sufficient to cause the motor to perform badly, and to interfere with any automatic means of carburetion.

Motor Compression Is Bad

Editor THE AUTOMOBILE:

[2,285]—I have a single-cylinder car, with a 5-inch bore, which has been run four years. The packing rings in the cylinder are open at the ends 1-16 of an inch, and the compression is bad. Would you advise new rings put in? If so, should the open ends be at the bottom of the cylinder, or turned around so that the ends will be a quarter of a turn from each other?

Dallas, Texas. W. E. GARABRANT.

Replacing the piston rings with new and more perfect rings will be a step in the right direction, but it may not cure the difficulty. The illustration as here given shows two pistons which were photographed after the compression became bad, and the information afforded will bear upon your case. The piston at the left shows unequal wear at P1. This condition suggests that the bore of the cylinder was also worn to an elliptical formation, and it was found in practice that replacing the piston rings did not cure the difficulty, because the new rings, while they were good and true, would not conform to the elliptical curvature of the cylinders, and leakage went on as before. The top ring of the same piston, marked R4, broke off at the joint, because the ring was too large for the bore, and it buckled up, resulting in a fracture at the weakest point. The piston at the right shows substantially the same difficulty, affording, however, the additional advantage of showing the blackened zones on the rings, which were caused when the rings buckled up, due to the fact that they were not left sufficiently open at the joints. In making a repair of this character, it is necessary to regrind the cylinder, if it is not true, and replace the rings if they are not in good order.

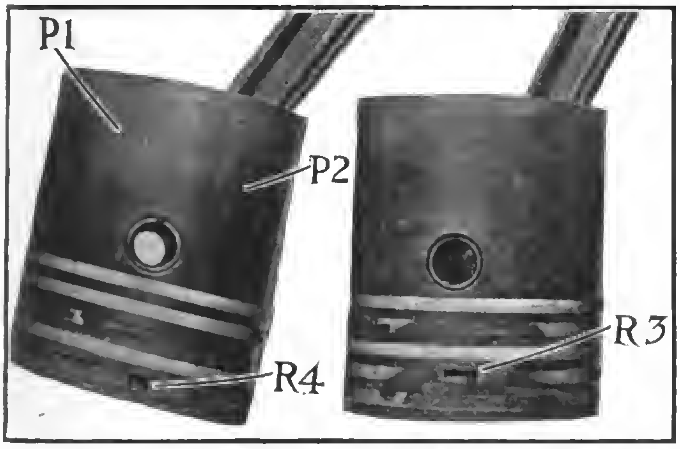

Fig. 2—Reproduction of worn out piston and rings showing how piston deformed and the rings fractured because the space at the joint was insufficient.

Magnetism in the Core of a Coil

Editor THE AUTOMOBILE:

[2,286]—I do not understand how magnetism circulates in the iron core of a spark coil. What has the iron to do with it?

Buffalo, N. Y. NOVICE.

Referring to Fig. 3, the "lines of force" are indicated by a series of loop-like lines, some of which pass through the ends of the core, and others through the diameter. When an electric current is impressed on the windings around the core, magnetism is set up in the iron core. This magnetism would be present were there no core of iron, but the magnetic flux would be less dense per unit of area in the absence of the iron core because the magnetic reluctance of air is far greater than that of iron. The iron, therefore, is utilized for the purpose of intensifying the density of the magnetic flux, so that the secondary electromotive force of the coil will be a maximum. The iron used must be of a special soft grade, of great purity, and preferably in the form of a bundle of wire. The density of the magnetic flux will be maximum at the mid-section between the boundaries A—B and A1—B1, tapering off towards the end as indicated.

Which Is Better, Long or Short Stroke?

Editor THE AUTOMOBILE:

[2,287]—One prominent manufacturer of motor cars makes a long-stroke engine, 6-cylinder, 40 horsepower, and puts up some fine arguments in its favor, yet in their larger car the engine is 5¾ x 5½. This is puzzling to laymen. Will you please enlighten?

Birmingham, Ala. ZIMMERMAN.

Not necessarily either. It is presumed that you mean when you say, "the stroke is long" that the length of the stroke exceeds the bore of the cylinder. Taking this for granted, the question of the advantage of the long stroke is one which cannot be discussed on an abstract basis. The world is so full of long stroke motors, which are wholly incapable of serving as power plants for automobiles, that it would lead one to the conclusion that the quality of a motor is not merely wrapped up in the ratio of bore to stroke. There are a hundred things to consider, and when they are all reduced to a relation involving harmony, the motor may be thoroughly good with a long or a short stroke. Lengthening the stroke, if the design is proper, adds to the power of the motor, considering a given bore. On the other hand, increasing the bore adds to the power of a motor for a given stroke.

What Has Color of Spark to Do with It?

Editor THE AUTOMOBILE:

[2,288]—Please answer in your inquiry columns, which is the best spark for a coil, a blue or a yellow spark? SUBSCRIBER.

Plainfield, N. J.

The spectroscope, which is an instrument employed in determining the composition of bodies by color comparison, has never been successfully employed in connection with the spark at the gap of a plug in an ignition system of an automobile. The best spark is the one which dissipates the largest amount of energy in the gas, and the measurement of the energy cannot be accomplished by the simple method of gazing at the spark and deciding that it is good because it is yellow, or better because it is blue. It would be something of a gain were one to be able to arrive at the conclusion that the spark is "vicious." This is not even possible by measuring the electrical energy.

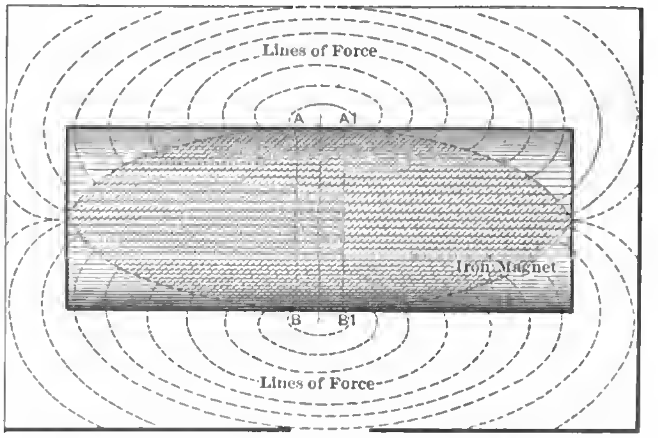

Fig. 3—Illustrating lines of magnetic force in the soft iron core of a spark coil showing how some of the lines short circuit through the diameter.

Forced Lubrication

(First Installment.)

By R. K. MORCOM, Mem. I. of A. E.

Paper read on Wednesday, May 11, 1910, at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S. W. Dr. H. S. Hele-Shaw, F.R.S. (President of the Institution), in the Chair.

THEORY and practice of lubrication are subjects of such importance that it is not surprising to find a very extensive literature on them.

The mathematical theory has been well treated, and experimental figures of a varied nature are available to confirm or correct the theoretical treatment. While taking for granted the established results of those who have investigated the matter, it may be useful to any who wish to refer to the original communications to give a slight bibliography.

Beauchamp Tower—Proc. I. M. E., 1883, 1885, 1888, 1891. Reports on Friction Experiments. These classic researches were made chiefly on pedestal and saddle bearings. The pressures were taken to high figures. but the speeds were not high. The investigations on the oil film are particularly interesting.
Osborne Reynolds—Trans. Royal Society, 1886. This gives a full mathematical treatment of Tower's results, and may be taken as the foundation of the modern theory of lubrication.
Nicholson—Trans. Manchester Association of Engineers, 1907-8. A useful paper and discussion. It co-ordinates the results of various investigators, among others—
Stribeck (Z. d. V. d. Ing. September 6, 1902).
Helmann (Z. d. V. d. Ing. Vol. 49, p. 1161).
Sommerfeldt.
Ewing and Jenkin—Phil. Trans., 1879. On starting from rest.
Lasche—Traction and Trahsmission. January, 1903. Also published separately, "On the Design of Bearings for High Speeds." An interesting account of experiments for the A. E. G. Radiation from and cooling of bearings and variation of temperature from point to point are among its most interesting sections.
Morcom—I. M. E., 1897. Deals particularly with double-acting engines using forced lubrication.
Goodman—Pamphlet on "Friction and Lubrication of Cylindrical Journals," 1890.
Archbutt and Deeley—Treatise on "Lubrication and Lubricants."
Thurston—"Friction and Lost Work."

A number of other papers might be quoted, but these give considerable information and fairly cover the ground.

The one outstanding conclusion is that the modern theory of lubrication is the theory of the oil film. The old ideal of a coefficient of friction gives place to the more suggestive theory that the resistance to motion is due to the shearing of a film of oil, which more or less completely prevents metallic contact and abrasion. The importance of the film is shown by considering that the resistance of a fully lubricated surface may be only one per cent. of a similarly loaded surface in which an oil film is not maintained. Resistance to shearing depends upon the viscosity of the lubricant, thickness of the film, and the area of film in shear. The temperature of the film may alter its viscosity; the extent of the film may not be equal to the extent of the bearing; the thickness of the film may not be such as to entirely prevent abrasion, and the clearance in the bearing may be irregularly distributed and inaccurate, and similar disturbances may be created by bad alignment of the shaft or its springiness, so it is not possible to entirely solve the problem. As usual in engineering, theory may direct or explain practice, but experience must determine it. Certain positive conclusions, however, may be taken as established:

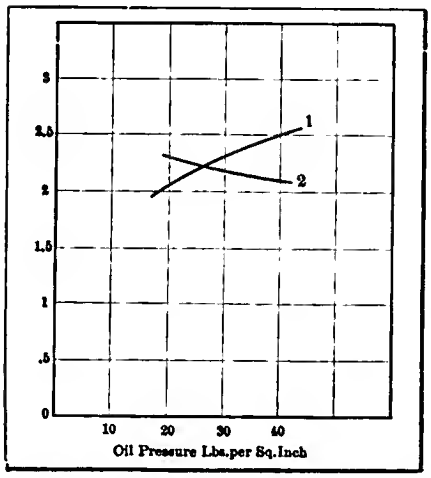

Fig. 1—Chart which is designed to give the horsepower with loads of 186 pounds and 5,130 pounds respectively

(1) The resistance decreases with the thickness of the film.
(2) The resistance increases with the viscosity of the lubricant very materially.
(3) The point of nearest approach is approximately 90 degrees from the line of load.
(4) The points of maximum and minimum oil film pressure are approximately at equal distances from the point of nearest approach.
(5) As the speed increases the points of maximum and minimum oil pressure get further and further apart, till at very great speeds they are in the line of load.
(6) As the speed increases the eccentricity of the oil film becomes less.
(7) The concentric position is the one of least resistance.
(8) Oil should be supplied at a point where the supply pressure is greater than the film pressure.
(9) The loading for a given speed must not exceed a certain limit at which the oil film is broken.
(10) This limit may be increased by lengthening the bearing, so increasing the cooling influence on the bearing.
(11) Oil grooves wrongly placed may destroy continuity of the film.
(12) A motion of pure rotation produces automatic maintenance of the film, provided the supply is adequate.
(13) The temperature varies throughout the bearing, the highest temperature being at the point where the film is thinnest.

Further, in the case of a reciprocating load we know that

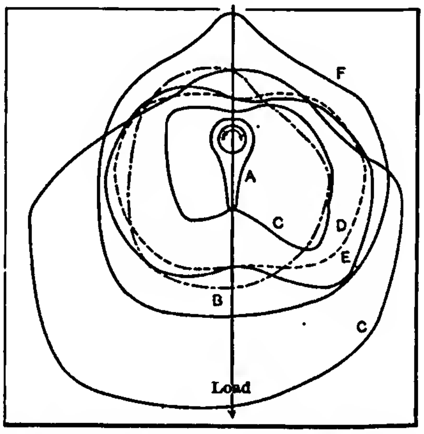

Fig. 2—Diagrams of oil pressures at various points given in section to clear the text

(1) A reciprocating load irrespective of rotation produces automatic lubrication.
(2) Heavier mean loads can be supported if the direction of load is reversed, because the lubricant is more vigorously sucked in, and the retardation of surfaces approaching one another normally increases very rapidly as the film becomes thinner.

Generally speaking, failure of lubrication is caused by rupture of the film due to:

(a) Inadequate supply of lubricant
(b) Reduction of the viscosity arising from excessive heating, either general or local.
(c) Badly placed oil grooves.
(d) Overloading.
(e) Grit.
(f) Impurities, such as water, reducing the film-forming quality of the oil.

Assuming that the bearings are not overloaded, that system of lubrication will be best which best ensures that other causes of failure shall not occur.

The more one studies the question the more does forced lubrication best appear to meet the requirements. Its acknowledged superiority over other systems for high-speed steam-engines suggests its adoption for the motor car engine. Various splash and gravity systems have been very carefully designed and worked out for car motors, and the success attained is great—so great that it is easy to argue that the success is good enough. But practice in the long run always pronounces in favor of the theoretically best, and it is this which explains the increasing favor with which pressure supply meets.

In the last installment of this article will be given particulars of the lubrication systems of a number of well-known motor cars. There are no fewer than eighteen examples using oil under pressure. The data which various manufacturers have kindly supplied will, it is hoped, serve not only to establish this point, but also to indicate accepted practice as regards the arrangement, etc.

There is considerable difficulty in obtaining full figures and particulars of up-to-date results and methods, such as oil consumptions, oil temperatures, wear over long periods, oil grooves, etc., and the table is necessarily long and incomplete. In fact, information about forced lubrication, both descriptive and experimental, is rather scanty. Nearly all the experimental work has been done on bearings lubricated by other systems.

Some experiences with forced lubrication do not at once fit in with theory, and it may be of interest to describe a few observations and experiments.

One of the most obvious things to examine was the actual saving in friction, if any, which occurred with forced lubrication. A trial was made on a 120 b. h. p. engine at 450 revs. per minute. The engine was run unloaded with oil pressures of 30 lbs. and 5 lbs., and without pressure, the supply being maintained with a syringe. A large number of no-load cards were taken and the i.h.p. averaged out. The results of the trial showed:

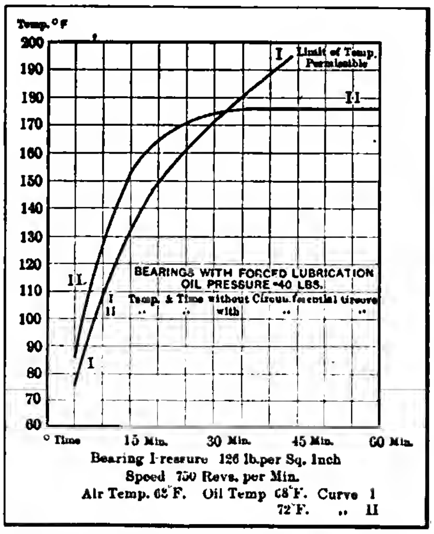

Fig. 3—Bearings with force feed lubrication with a pressure of 40 pounds per square inch, showing resultant temperatures

(1) That the engine was quieter the higher the pressure.
(2) The friction i.h.p. averaged 2.13, 2.41, 3.33, with 30, 5, 0 lbs. pressure respectively.

There is some trouble in explaining this result, for one would expect the cooler oil and more complete oil film with the higher pressure to increase rather than decrease the resistance. Some light is thrown on the case by the quieting action, which means that the film thickness in reciprocating bearings was better maintained. In addition such a result may occur in a steadily loaded bearing, owing to the more copious supply preventing excessive local heating of the film, leading to rupture. This is borne out by the experience that an engine with forced lubrication takes longer to "run in" than one with splash or gravity supply, and further that its bearings take longer to take up a high polish.

Such a result was obtained in an experimental bearing.

A 4 in. shaft was run at 1,000 r.p.m. in two bearings 10 in. long; between these was a bearing 10 1-2 in. long, loaded by means of a spring and lever. The outer bearings were supplied by a gravity supply, the inner at varying pressures. The journal was driven by an electric motor. Curves 1 and 2, Fig. 1, give the horsepower with loads of 186 lbs. and 5,130 lbs. respectively. The temperature was 168° F. in the one case and 200° F. in the other when run for some time at 25 lbs. pressure oil supply.

A series of trials were taken with a load of 24 lbs. per square inch on a bearing 10 in. long by 4 in. diameter. The bearing had a horizontal oil groove cut, and this was tried in four positions:

(1) On the loaded side.
(2) Opposite the load.
(3) On the right-hand side at right angles to the load, with rotation as in Fig. 2.
(4) Opposite to (3).

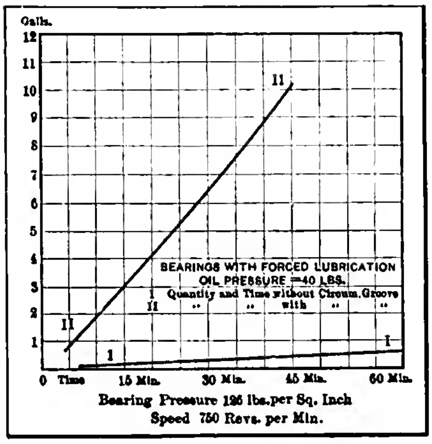

Fig. 4—Chart of the quantity of lubricant circulated, giving the time, speed and pressure

Diagrams were taken of the oil pressure at various points, a selection of such diagrams being given in Fig. 2. The curves may be compared with those composed by Dr. Nicholson from Sommerfeldt's figures.

The index to the curves of Fig. 1 is as follows:

A. 500 r.p.m. 20 lbs. per sq. in. oil pressure.
Groove position (1) 24 lbs. per sq. in.
B. 1,000 r.p.m. 20 lbs. per sq. in. oil pressure.
Groove position (2) 24 lbs. per sq. in.
C. 1,000 r.p.m. 20 lbs. per sq. in. oil pressure.
Groove position (1) 24 lbs. per sq. in.
D. 1,000 r.p.m. 40 lbs. per sq. in. oil pressure.
Groove position (1) 24 lbs. per sq. in.
E. 500 r.p.m. 40 lbs. per sq. in. oil pressure.
Groove position (1) 24 lbs. per sq. in.
F. 1,000 r.p.m. 40 lbs. per sq. in. oil pressure.
Groove position (2) 24 lbs. per sq. in.
G. 660 r.p.m. 20 lbs. per sq. in. oil pressure.
Groove position (2) 126 lbs. per sq. in.

Run at 1,000 r.p.m. and 40 lbs. per sq. in. oil pressure, the final oil temperature reached was taken and found to be:

Oil groove in position (1) 74° F. above air temperature.
" " (2) 62° F. " "
" " (3) 60° F. " "
" " (4) 62° F. " "

It would appear that position (3) is the best position.

A further series of trials were run at heavier loads with spring loading. It is unnecessary to give the trials in detail. The most important conclusion to be drawn was that the benefits of forced lubrication were best realized with a circumferential groove, which enabled heavy loads to be taken at high speeds.

As an example, the curves in Figs. 3 to 5 give temperature, e.h.p. and quantity of oil passing with 126 lbs. per sq. in. loading, 750 r.p.m. and 40 lbs. oil pressure. The curves II. are with circumferential groove; the curves I. are with two horizontal grooves 2 1-2 in. apart on top of bearing, joined by a short circumferential arc.

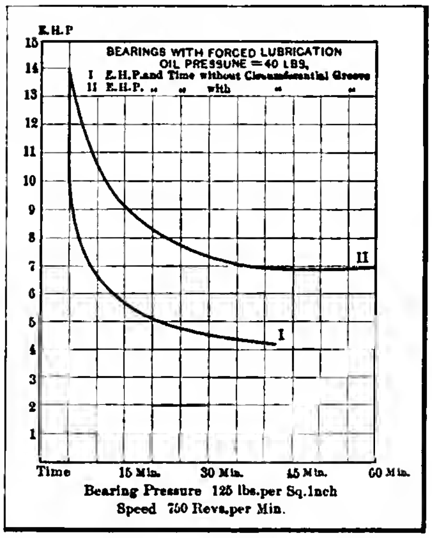

Fig. 5—Chart of the relation of power and time with lubricant circulating under a pressure of 40 pounds per square inch

The Wrong Way to

Fig. 1—In approaching an automobile to pass it, if it is desired to get into trouble, pass it on the right, as here shown

INFORMATION for the owner seems to be of the varied sort, with enough and to spare, especially if account is taken of the apparent fact that the "good advice" so freely offered betimes is rarely taken seriously. Perhaps the character of the material is below the level which merits notice; it may be that it is too freely offered, or the true answer to the enigma may lie in some long-forgotten channel. At all events, it seems as if some way ought to be contrived which will fill the want. That there is a vacancy is assured from the very fact that accidents do happen with almost slavish regularity, and when the reason is sought out, it generally results in disclosing a lack of appreciation of the good that is in the "rules of the road."

If the average beginner cannot be reached by any method of telling a direct story, it may be that a reversal of the direct method will serve the purpose. How not to drive, then, is the gist of this plaint, and in order to be able to tell it in the language that will carry conviction, it was considered necessary to take two automobiles out on the highway, and have the "staff photographer" record the doings. The illustrations offered with this article do not represent the actual happenings of autoists who violate the principles of safe and legal driving, but they do show how to go about it if accidents are courted.

Some of the Relations of Automobiles to Roads

The power plant of the automobile is there placed to propel the car; it furnishes the stamina, so that when it is desired to go, it is necessary to turn on the power. The power plant, then, is placed to accomplish a certain purpose, but it must be understood that it is also capable of being the source of damaging occurrences. When the automobile is brought up to speed, it is necessary to steer it along the roadway in such a way that it will keep on that part of the same that is fit to run over, and it is also desirable to avoid trying to occupy space that is taken up by another automobile or a horse and wagon.

If the automobile is going faster than a vehicle ahead, it follows that it is either necessary to slow down, or turn out in order to clear the vehicle ahead during the period that both vehicles are abreast of each other on the road. In order to slow down, if that is the choice, brakes must be used, and, while they are supposed to stand a considerable amount of rack, the fact remains that they do hard work, and they are likely to become deranged. If it is desired to generate an accident just at such a time, the right way to go about it is to have the brakes in a state of bad repair, so that, when it is necessary to bring the automobile to a stop, or to slow down, they will be incapable of performing their proper functions.

Fig. 2—In order to smash a front axle, or damage the steering gear, take to the tall grass to one side of the road and engage, at close quarters, a concealed boulder, as here indicated.

Fig. 3—How the automobile was elevated sufficiently for the front axle to lift clear of the boulder shown in Fig. 4

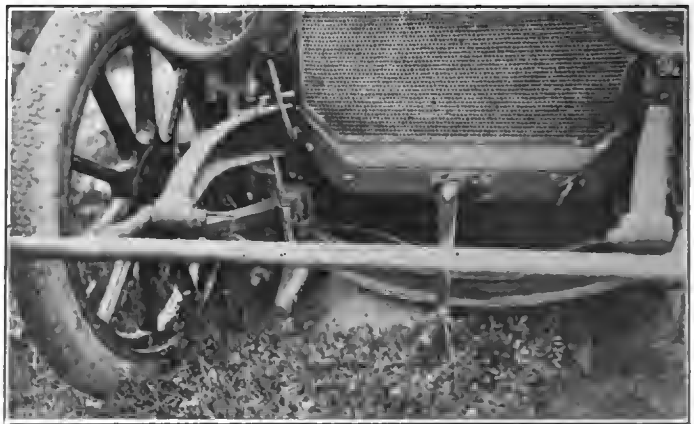

Fig. 4—The boulder on which the front axle rested after it was driven on the wrong side of the road in passing a car ahead

If it is desired to pass the vehicle ahead, the next question is, how will it be done if it is proposed to have a rear-end collision with the car ahead, or to damage the car which is in the position of having to pass the other. Fig. 1 is offered as the right way to pass a vehicle ahead in the process of looking for trouble. In this case, as the illustration portrays, the rear automobile was held in check until the roadway was narrow, and it was then turned to the right instead of to the left, then accelerated in order to make more speed than the car ahead, and started on its course to certain ruin.

Drive an Automobile

While it is true that the plan was merely to illustrate the way which leads to trouble on the road, the joke proved to be on the experimenters, and as the rearmost of the two automobiles plowed its way through the grass on the wrong side, it intercepted a boulder which was hidden by the tall grass, as shown in Fig. 2, with the result that the front axle of the automobile bounced up and landed fair on the top of the boulder after driving the same ahead for upwards of six inches, in addition to forcing it into the earth for a distance.

Trouble Came in the Form of a Boulder

Fortunately, the front axle was a stout one, and the only problem was to get the stranded automobile off the rock. This

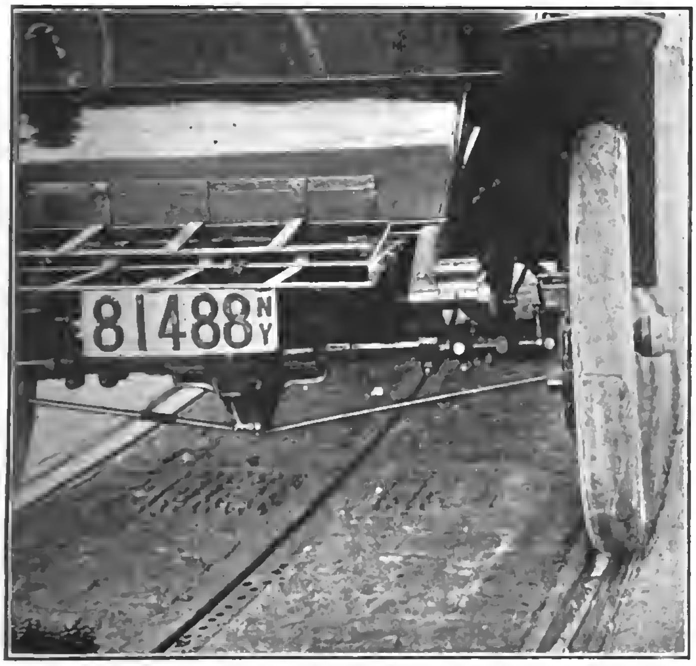

Fig. 7—To damage the tires beyond repair, run in the curve of a car track after it is frayed out, as shown

was accomplished in the manner as shown in Fig. 3, in which a wedge-shaped rock of sufficient height was placed back of the front wheel, and the automobile was then backed off of the rock; it raised up, and the rear axle then cleared the rock. A close examination of the axle indicated that it was not damaged, although the blow was a severe one, and the method is recommended as the very one which is likely to destroy even a good axle, in nine cases out of ten, but an axle of poor construction is bound to be fractured every time.

Just how the automobile looked when the front axle was resting on the rock is possible of discernment by a close examination of Fig. 4, although it proved too dark beneath the car to get a good photograph of the rock and the axle at that point.

The Best Way to Be a Graduate Road Hog

Among the accomplishments of the man who wants to drive wrong must be numbered the one which will enable him to get up a reputation for being what is tersely termed a "road hog." In order to show how it is done, the two automobiles were taken to a road that is narrow, and the one ahead crowded to the left of the road so that the one behind was offered no opportunity of passing excepting on the wrong side. Fig. 5 is a fair illustration of the method, and it is believed that any-

Fig. 5—How a road hog takes to the left of a narrow road to prevent any other autoist from passing him

one, even in the absence of any great skill, will be able to perform the feat at will. All that is required is an automobile and the desire to be mean with a certain studied ingenuity.

How to Damage the Tires With Small Effort

A very good way is to carelessly back up against a formidable obstruction as shown in Fig. 6. Find a narrow roadway, run up it for a distance and then decide to turn around, rather than to see it through. In turning around, throw in the reverse, speed up the engine, then throw in the clutch, and finally back the automobile up against any obstruction that happens to be in the line of travel. Still another good way is to run in the street car tracks just where they are frayed out, as on a curve. Fig. 7 is a good average example.

With the rubber market soaring skyward, and but small chance of a downward trend in the near future at any rate, it is believed that this illustration of the method by which tires may be cut to pieces in a short while should prove of great value to those who prefer to do things the wrong way.

One point, bearing upon the question of destroying tires, was carelessly overlooked. If the tires are more or less flat they will bow to this treatment much better. In order to hasten the destruction of the tires, run them insufficiently inflated. Ordinarily they are inflated (each one the same as the other) to about 80 pounds per square inch, considering the 34-inch sizes (other sizes to correspond), and this full and even inflation protects the tires under the most adverse conditions.

Fig. 6—In backing up, if it is desired to damage the automobile, be careless and back into an obstruction, as shown

Report of Cast Iron Test Bars*

(First Installment)

FOLLOWING closely upon the reading of the paper upon tests of cast-iron bars, many other experimenters presented their results in the same field of endeavor. Thus Prof. W. B. Gregory spoke as follows: The writer has recently made a large number of tests of cast-iron specimens of one-inch square cross section and with supports 12 inches apart, a few being also broken in tension. The results confirm the deductions of the author as to the relationship between breaking loads in tension and in cross bending. The ten-to-one ratio holds in these tests as in those given by the author. Table 1 gives the results of the cross-bending tests, the load being applied at the center.

TABLE 1. TESTS IN CROSS BENDING

Specimens 1 In. by 1 In., 12 In. Between Centers, Load Applied at Center

No.	Breaking Load Lb. per Sq. In.	Deflection In.
1	2,280	0.10
2	2,250	0.10
3	2,680	0.09
4	2,410	0.09
5	2,250	0.08
6	2,870	0.09
7	2,240	0.09
8	2,310	0.08
9	2,250	0.09
10	2,470	0.08
11	2,180	0.10
Mean	2,335	0.09

From the specimens broken in cross bending, six were selected from which were turned tension test pieces approximately one-half inch in diameter at the smallest section, their length over all being five inches. The threads at the ends were three-quarter inch outside diameter. The test pieces were made to fit loosely into the tension bars of the testing machine so that side stresses were entirely eliminated, and the specimens were broken in pure tension. The results are given in Table 2.

TABLE 2. TENSION TESTS

No.	Breaking Load Lb. per Sq. In.
1	22,900
2	23,300
3	22,800
4	23,550
5	24,600
6	22,050
Mean	23,200

The ratio of tensile strength to load in cross bending is

$$\frac{23200}{2335} = 9.94$$

This comparison can be made only on the basis of averages, as no record was kept of the numbers of the specimens broken in cross bending. The six tension specimens therefore represent six of the eleven specimens broken in cross bending. Specimen No. 9 of the cross-bending tests may be taken as fairly typical of the others. A chemical analysis was made of this specimen with the following results:

Total carbon	4.04
Silicon	1.76
Phosphorus	0.562

The mean deflection as given by the author averaged 0.45 inch for two sets of specimens and 0.44 inch for another set. The highest value of deflection in any case was 0.50 inch. Since the deflection varies as the cube of the length of specimens between supports, it follows that the deflection for specimens tested with supports 24 inches apart should be eight times the deflection for a length between supports of 12 inches. On this basis the specimens tested by the writer should have

$$\frac{0.45}{8} = 0.056 \text{ in.}$$

deflection instead of 0.09 inch average as the tests showed. Can this discrepancy be explained by the difference in chemical composition or is it due to other causes?

This raises the question of what deflection ought to be specified for one-inch square specimens with 12 inches between supports. Some specifications have recently been brought to the attention of the writer in which the minimum deflection was placed at 0.15 inch. Is this commercial cast-iron or does it call for a special mixture, expensive and hard to obtain?

The author has mentioned that the "skin of the metal" was of no appreciable thickness. I would like to ask if he has ever tried the effect of rattling on specimens. The process of rattling will remove the sand and the skin of the metal. In this connection the results in Table 3 may be of interest.

TABLE 3. TESTS OF CAST-IRON IN CROSS BENDING

Specimens Round, 1¼ In. in Diameter, 12 In. Between Centers. Not Rattled

No.	Breaking Load Lb.	Deflection In.	Remarks.
1	2,450	0.075	Cast in pairs on end
2	3,010	0.08	" " " " "
3	2,670	0.07	" " " " "
4	2,580	0.14	" " " " "
5	2,700	0.09	" " " " "
6	2,580	0.14	" " " " "
7	2,620	0.08	" " " " "
8	2,430	0.075	Cast flat
9	3,360	0.09	" "
10	2,750	0.08	" "
11	2,990	0.09	" "
12	3,170	0.09	" "
13	2,950	0.095	" "
14	2,960	0.12	" "
15	3,080	0.10	" "
16	2,580	0.075	Cast on end
Mean	2,805	0.093	

The tests given in Table 4 are on specimens of the same size as those in Table 3. The metal used was as nearly the same as the foundry could make it and the specimens were placed in a rattler and the sand and "skin" removed by abrasion. From these figures it will be seen that rattling has increased the strength of the specimens, the increase being 3474 — 2805 = 666 which divided by 2805, gives 23.85 per cent. This phenomenon has been noticed by other experimenters.

TABLE 4

No.	Breaking Load Pounds.	Deflection Inches.
1	3,750	0.09
2	3,330	0.095
3	3,400	0.08
4	3,520	0.09
5	3,640	0.09
6	3,640	0.10
7	2,760	0.075
8	3,670	0.095
9	3,060	0.09
10	4020	0.10
11	3,440	0.09
Mean	3,474	0.0904

The statement that rattling increases the strength by about 25 per cent. seems to be borne out by experiments. The increased strength is probably due to a removal of some of the internal stresses in the specimens and to the fact that the particles of iron, by the process of tumbling the bars together, are allowed to arrange themselves so that they are better able to resist stresses than they were before rattling.

Since the breaking load varies directly as the moment of inertia of the cross section of the specimen about the gravity axis, we have

I_g for the specimens 1¼ in. diameter $= \frac{1}{4}\pi r^4 = 0.7854 \times 0.625^4$ $= 0.12$

*Discussion following the presentation of a paper of this title at the October meeting of the American Society of Mechanical Engineers, Galveston. The discussion is by Prof. W. B. Gregory, the author of the original paper, and others. This paper was designed to show engineers that test pieces, whether cast in separate molds or in the same mold as the main casting, are not perfect indications of the character of the iron in the main casting. In other words, uniformity of results is not found in practice where we know of no reason why they should not be uniform. These test bars were used in the construction of over 3,000,000 pounds of pumping-engine castings, involving soft and hard irons for the various parts.

Ig for the specimens 1 in. square $= 1/12\, bh^3 = 1/12 = 0.0833$

Then

$$\frac{0.1203}{0.0833} = 1.44$$

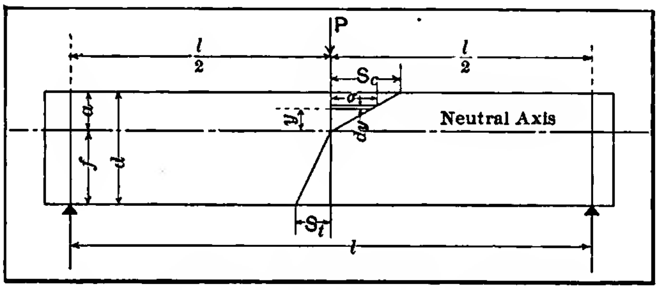
Making the comparison between the unrattled round specimens and the square ones, we have

$$\frac{2805}{2335} = 1.2$$

Comparing the rattled round specimens with the square ones we have

$$\frac{3474}{2335} = 1.487.$$

GEO. M. PEEK. The paper brings up a point which I have had in mind for some time, and which I have never seen explained in any of the text books on the strength of materials or any of the engineer's hand books. The formula is obviously not applicable to cast-iron beams, for the reason that it assumes that the neutral axis of a rectangular beam is in the center, which is true only when the beam is made of a material with equal tensile and compressive strengths.



Sketch of beam to show loading and neutral axis

Automatic Stability in Aeroplanes

(Second and Last Installment)

ADAPTED FROM THE GERMAN BY MARIUS G. KRARUP.

CONSIDERING the gyroscope, if it is forced to take a new angle in spite of its resistance, and this change of angle has to be large, it is liable to follow the lines of smallest resistance, in ways at present difficult to foresee, the difficulty arising largely from burdening it with work too heavy for its capacity in order to avoid a weight which could not easily be carried.

The uncertainties in applying the gyroscope principle are evidently best obviated by reducing the weight of the apparatus to, say, 10 kilos and asking of it a very much reduced amount of work, as may be done on the relay principle by suspending the gyroscope free to turn in relation to the whole machine but capable of actuating the control surfaces by the intermediation of compressed air provided by the power of the motor. In the absence of such feeler-organs as above referred to, it seems unfortunately possible, however, that any operation of the gyroscope may come too late if it can only begin when the machine as a whole has already begun to lose its balance.

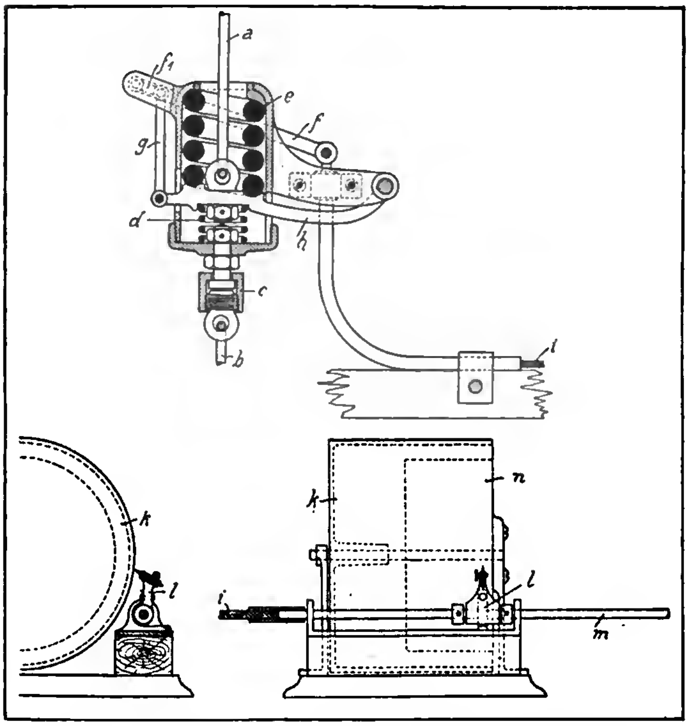


Fig. 2—Dynamometer for measuring stresses in aeroplanes

While this might interfere with the usefulness of the apparatus under an extraordinary combination of unfavorable circumstances, it is equally clear that the device would normally be very useful. The speed of flight is from 20 to 30 meters per second, and if the gyroscope requires only one-third of a second for actuating the control surfaces automatically, danger would in practically all cases be averted, especially if it is assumed that most accidents are due to wrong operation by the aviator and that the gyroscope intelligently applied would not be capable of making mistakes. The experiments made with chrome-nickel steel disks revolved at very high speeds in connection with steam turbines render it certain that the gyroscope can be made to function for a considerable time after the motor has been accidentally stalled, and that it will continue to serve its purpose for safeguarding a landing after such stalling of the motor has occurred.

While the gyroscope is an expensive apparatus, even in the small sizes proposed, it is not generally realized what sums it would save, if it is assumed that it will keep the aviator from committing errors in the control movements at critical moments. The disciples of aviation usually break at least one machine to bits before they learn to operate with safety. Something quite normal is that the learner applies the tilt rudder too strongly, so that the machine suddenly rises in the air, loses its speed and then tumbles down backward. According to the French method of teaching, the learner places his hand upon the arm of the instructor in a number of flights and is expected to await the time patiently when he shall be able to gauge the required control movement instinctively, before a machine is entrusted to him. No doubt, the small gyroscope is capable of obviating the drawbacks in this condition, but it would be advisable to make the most careful experiments before incorporating it in aeroplane construction. It might be taken on board and connected with a registering device, but not with the actual control apparatus, and the latter could be connected with a similar registering device, and the results could be compared. Finally, when it was found that the gyroscope functioned correctly, the control could be entrusted to it. But every automatic balancing device should earn its pilot diploma first.

Automatic stability once secured, most of the other safety measures which have been proposed become superfluous. An auxiliary motor seems an unnecessary complication, whether it is conceived as an independent prime mover or in some form of stored power operating when required, on the shaft of the main motor. If the brains and energy which would be needed for perfecting arrangements of this order were employed in improvements of details in the present simple construction, with weight added to the motor, if necessary to produce the maximum of reliability, and weight saved at all other points of the structure, wherever possible, there would seem to be more promise of dependable results.

The question is where and how weight can be saved. It is impossible to arrive at an answer to this question by figuring. No one knows what the force of a gust of wind is and how it attacks each part, nor how gradually a landing may be effected under this or that condition of weather and ground surface. It will therefore be necessary to treat the whole machine as a large dynamometer and to undertake experiments for determining just what is the force of the normal and abnormal shocks occurring in the operation of an aeroplane. An apparatus will be required for registering the shocks and stresses graphically, and probably the suspension and guy wires are the parts at which this may be most practically done. The pull on a wire may be measured without a break in the wire (as Mr. Conrad proposes to show on another occasion), but the most convenient arrangement, as sketched in Fig. 2, involves the attachment of the dynamometer between the wire ends *a* and *b*; *g*—*h*—f_1—*f* is a lever transmission which draws the Bowden wire *i* to and fro; *d* is an auxiliary spring, *c* the swiveled connection for wire end *b*. The registering device with drum *K*, clock *n*, pushrod *m* and stylus *l*, are actuated direct from the Bowden wire. More than one stylus might be used, of course.

An apparatus of this order may be placed at any point where it is desired to ascertain the stresses under different conditions of flight, starting and landing, and by continued experimenting on these lines it will be learned where weight may be economized and where strength should be added.

(The translator fears that any stress upon a wire connected as proposed will be immediately transferred to other wires or parts of the structure, as soon as the dynamometer begins to operate, and that the author's idea must be carried out in a different manner.)

To further augment the safety derived from the installation of a small gyroscope acting on the control areas and from improvements in details of construction under guidance of experiments with suitable dynamometers, it would probably be advisable to keep in mind the desirability of a design permitting the aviator to see the ground on which he is to land and over which he must travel for some distance at every start. But the best protection consists, after all, in cultivating that indefatigable habit of inspecting every part of the machine, wire after wire and nut after nut, of which Wilbur Wright has set the example.

The Tails of Aeroplanes Discussed

BY a number of experiments, most of the French and German aviators have satisfied themselves that a trailing tail secures steadiness of flight, and this construction feature has therefore been incorporated in nearly all fliers. Accidents happening to those machines whose tails remain short are pointed to as confirming the general opinion. An example is illustrated herewith, the photo showing the precipitous descent of a monoplane designed and piloted by Robert de Lesseps, one of the sons of the builder of the Suez Canal. Even the German and French Wright biplanes are now provided with caudal appendages, and it is a matter for conjecture whether the Wright biplanes of American manufacture will be similarly equipped or not. The French Wright machine illustrated herewith is not in reality, however, equipped with a tail, as claimed by the advocates of this feature who would fain place the Wrights in the light of imitators. A tilt-rudder has been added in the rear, to be sure, and will serve to steady flight, as the true tails do under average weather conditions, but this tilt-rudder is under control from the driver's seat and thereby obviates the principal objection to tails with immobile horizontal "empennage" or stabilizing planes; namely, that of adding an element which is under control by the wind and not by the aviator and therefore as much a source of danger in sudden gusts of wind as of comfort when the wind is steady or in a calm. With many aviation meets in progress or in prospect, each subsidized with valuable prizes, it is perhaps only natural that the European designers should adopt the tail as a palliative for shortcomings in the balancing qualities of their machines rather than try to devise a radical remedy, since they will not be required to fly at the meets or for the prizes in the kind of trying weather in which the drawbacks of the long tail and of all other inert wind-catching features in the construction will be put to the test. Appendages, such as that of the new French Wright model, in which the entire surface is under control, belong, of course, in a different class, and it seems likely that a single tilt-rudder in front and another in the rear—where it will also forewarn the aviator of sudden currents from behind—will prove preferable to a double tilt-rudder in front alone, particularly as the two tilt-surfaces may be operated by the same control movement.

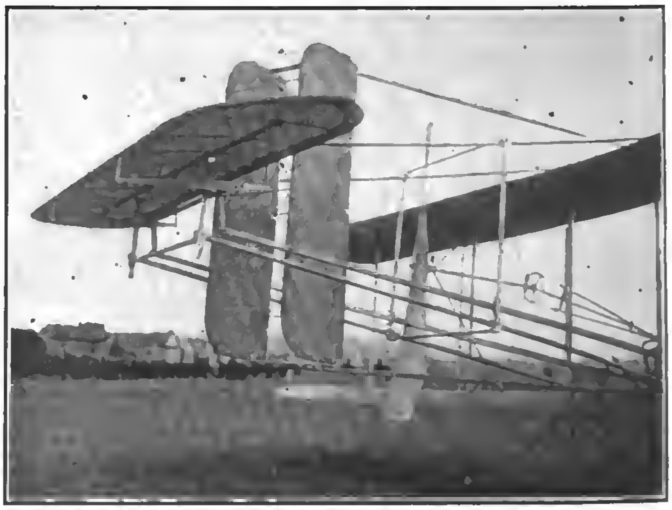

Fig. 2—New Rear Tilt-Rudder of French-built Wright Biplane

The New Motor Vehicle Law of New York

Its Provisions, Operation and Effect

By XENOPHON P. HUDDY, LL.B.

THE LEGISLATURE of the State of New York has enacted a new motor vehicle law and the signature of the Governor, which was affixed to this law on June 2, has finally settled the wrangling which has been going on in this State for a long time between opposing interests concerning automobile legislation. Not since the law of 1904 has the State of New York made any material change in regulating motor vehicles. One or two specific amendments concerning particular subjects have been enacted, such, for example, as allowing surety company's bail bonds to be given. The Legislature has also given a lien to garage-keepers, prohibited chauffeurs from using automobiles without authority and regulated toll for automobiles charged by toll bridges and roads. Aside from these nothing of importance since 1904 has been enacted by the Legislature at Albany except the new motor vehicle law which goes into effect August 1, 1910. This law is comprehensive and attempts to cover the entire subject. It repeals the law of 1904.

It may be said at the outset that the new automobile law is not in any sense a freak measure. On the whole it is a fairly good enactment. There are, however, some objections which may be made to certain of its provisions. It is undoubtedly a revenue measure of the highest type, but automobilists generally do not object to paying large registration fees such as are provided in this law, if the fees are devoted to the public highways. In consideration of the rather high fees—graduated according to horsepower—to be paid for registering automobiles they are exempt from any other tax, either State or local. This is a very wise and fair provision, since if high registration fees are to be paid there should be some compensation for so doing; therefore, automobiles have been relieved from property taxation, but whether this substitute for a property tax is legal is a very serious question. It is equivalent to saying that because automobiles pay a high license fee for using and maintaining certain property, they shall not be subject to ad valorem taxation on that property; or in other words, the license fees are not, in fact or law, license fees, but constitute property taxes.

The law starts out by defining the various terms used therein and the term "motor vehicle" includes all motor vehicles propelled by any power other than muscular, except motor bicycles, motorcycles, traction engines, road rollers, fire wagons and engines, police patrol wagons, ambulances and such vehicles as run only on rails or tracks. It will be seen that motorcycles are not included. They should not be included under an automobile law, and it was a precautionary matter for this law to expressly exclude them, for under the motor vehicle law of Michigan it is held by the Supreme Court of that State that the term motor vehicle includes motor cycles, unless expressly excluded.

Law Defines Chauffeurs and Drivers

The definition of the term "chauffeur" is very short, using less phraseology than the definition in the old law. The present law provides that the term chauffeur shall mean any person operating or driving a motor vehicle as an employee or for hire. This definition is inclusive and exclusive. Any person coming within the definition is a chauffeur. All persons who do not fit the definition are not chauffeurs, and consequently do not have to comply with the provisions of the law concerning employed drivers. I might say that the new law contains a defect which the old law possessed, and which defect is of great seriousness. Under the old law a person who was not a chauffeur and who did not own an automobile, could drive without obtaining a license. For example, a son might use his father's car and drive it all over the State without being compelled to obtain any kind of a license. So might a daughter do this, or any person may borrow or hire a car from another and drive it without being compelled to take out a license. The law has not remedied this situation except in cases where the *exclusive use* of a motor vehicle is given to another for a period greater than 30 days.

The phrase "exclusive use" means uninterrupted use. Therefore, it is nugatory and inoperative in attempting to remedy the defect of the 1904 law. No son or daughter or borrower who uses an automobile belonging to another person has the exclusive use of it for any great length of time. It is an occasional use of a motor vehicle by an unlicensed person which has caused much trouble. Then, again, the exclusive use must be for a period greater than 30 days. It is hard to conceive of a situation where a borrower of an automobile has the exclusive use of the same for a period greater than 30 days. If such a case should be contemplated it would be easy to arrange an interrupted use to get around any question of exclusive use for a period over the limited time. This feature of the new law is objectionable, and there can be no question about it.

Registration by owners of motor vehicles is made with the Secretary of State by filing a verified application containing a brief description of the motor vehicle, the character and amount of the motive power in figures of horsepower in accordance with the rating established by the Association of Licensed Automobile Manufacturers, the name and address and business address of the owner, and if the motor vehicle is to be used solely for commercial purposes the application shall so certify. It should be noted that the only qualification an owner must possess is age of at least 18 years.

The horsepower is to be calculated according to the rating established by the Association of Licensed Automobile Manufacturers. Evidently this law assumes that every one will take judicial notice of what the Association of Licensed Automobile Manufacturers is, and its formula for rating automobiles according to horsepower. Although the provision in regard to determining the horsepower may be perfectly valid, my opinion is it would have been in better taste if the formula adopted by the Association had been inserted instead of using the name of the Association of Licensed Automobile Manufacturers. This criticism may perhaps be more fanciful than real.

The fees to be paid for registering vehicles are: $5 for a motor vehicle of 25 horsepower or less; $10 for more than 25 horsepower and less than 35 horsepower; $15 for 35 horsepower and less than 50 horsepower; $25 for 50 horsepower and more; but when an automobile has been licensed under this law for a period of four separate years the annual registration fee thereafter is one-half of the amount. This does not apply to motor vehicles used solely for commercial purposes, the fee for which is $5 annually.

The owner of a motor vehicle used for pleasure is compelled to pay very much more for his pleasure than the proprietor of a commercial motor vehicle pays for registering the means which he places upon the streets for profit. It would seem that there should be no distinction between these two classes of motor vehicles in favor of commercial cars, and if any distinction is made it should be made in favor of the pleasure car, since an instrument which is earning money and represents an investment producing dividends should pay for its existence.

On the Sale and Transter of Automobiles

When an automobile is sold, the vendor must under the law give notice of the sale, with the name and address of the vendee, to the Secretary of State, and the vendee shall within 10 days notify the Secretary of State of the sale by filing a verified statement with the Secretary of State. The vendee must pay a fee of $1, upon receipt of which the Secretary of State will note the change of ownership. Upon the sale of a motor vehicle by a manufacturer or dealer, the vendee is allowed to operate the same for a period of 15 days after taking possession, until he has received his certificate of registration and number plates from the Secretary of State, but the motor vehicle must carry a placard bearing the registration number of the dealer or manufacturer. Application for registration must be made before the motor vehicle is used.

Provision is made for the registration of motor vehicles by manufacturers or dealers. The act reads that manufacturers and dealers *may* obtain a general license. The registration fee is $15. Duplicate number plates for manufacturers and dealers may be obtained from the Secretary of State upon the payment of $1 for each duplicate.

Non-resident owners are exempt from registering in the State of New York if they have duly complied with the laws of their home State and carry their home State credentials, provided their home State grants substantially the same exemption to residents of New York, but foreign corporations are not exempt.

This provision demanding the exemption by other States will have a most salutary effect upon New Jersey, where a special license must be obtained now for non-residents to enter that State. New York has always exempted non-residents, and the residents of New Jersey have always had the privilege of entering New York without obtaining any additional license. After the 1st of August residents of New Jersey will not be exempt in the State of New York.

The law provides that motor vehicles shall be equipped with adequate brakes, bell, horn or other device for signaling, and two lights on the front at night and one on the rear, displaying a red light visible from the rear. Two number plates must be carried, one forward and one on the rear. These will be furnished by the State, and the color will be changed annually.

Most important of all the provisions of the new law is that concerning speed. It is as follows:

"Every person operating a motor vehicle on the public highway of this State shall drive the same in a careful and prudent manner and at a rate of speed so as not to endanger the property of another or the life or limb of any person; provided, that a rate of speed in excess of thirty miles an hour for a distance of one-fourth of a mile shall be presumptive evidence of driving at a rate which is not careful and prudent."

The above speed provision, in the first place, will make it more difficult to convict automobile drivers of exceeding the speed limit, since exceeding 30 miles per hour for a distance of one-fourth of a mile is merely presumptive evidence of unlawful driving. An automobilist will be allowed to introduce evidence in defense to the effect that he was endangering no person or property, and if his speed was 50 or 60 miles an hour he cannot be convicted. It also should be borne in mind that a speed in excess of 30 miles must be maintained *for at least one-fourth of a mile*. No more will officers be permitted to catch automobilists on technical violations of the law for a distance of one or two blocks. When the automobile driver is caught it will be up to the police to prove their case, and it will be necessary to show, not only the excess of speed for a distance of at least one-fourth of a mile, but the prosecution must be prepared to show that there was danger created. Suppose no person was on the highway when an excessive speed was maintained. In the case of a chauffeur he might be found guilty because it might be said that he was endangering the automobile, the property of another. Whether a person driving an automobile could be convicted because he was endangering his own life and limb is a serious question, but it is possible that such a conviction would be legal.

Another question arises, and that is whether the excessive rate must be continuous for a distance of at least one-fourth of a mile. I believe it must be. If a driver slows down anywhere along the quarter-mile course to a rate less than 30 miles an hour, he cannot be convicted. Evidence introduced upon the part of the prosecution that the rate exceeded 30 miles an hour, which creates a presumption of imprudent driving, would not be sufficient to convict a driver since there is a presumption of innocence, and one presumption would merely balance the other. It is the duty of the State to prove its case beyond a reasonable doubt.

Power of Local Authorities Is Fixed

Local authorities, such as cities and other municipalities, may not impose any further tax or license on chauffeurs or exclude chauffeurs from the free use of the public highways, except where certain roads are set apart for horses, nor may local authorities in any way, respecting motor vehicles or their speed upon the public highways, pass or enforce any ordinance. There is a joker here in the law which will be pointed out presently. But municipal authorities may regulate automobiles offered to the public for hire. A certain highway may be set aside for speed contests under proper restrictions. Local authorities may also exclude motor vehicles from cemeteries and may also exclude commercial motor vehicles from parks, where the same reason exists for excluding other commercial vehicles.

The new law provides that it shall not impair the validity of any local regulation concerning the speed of motor vehicles made or hereafter to be made, which regulation would be authorized by law in any city of the first class. This is a rather peculiar provision. It does not authorize cities of the first class to regulate the speed of motor vehicles or to do anything else, and if such cities desire to regulate speed, they must find express authority from some other source. The new law is merely passive, and states that it will not itself invalidate any such regulations, but there may be other vitiating causes. This provision of the bill is certainly a joker, and the wonder is that it ever passed Governor Hughes, considering the stand he has taken in regard to according to the large cities power to regulate travel.

The local authorities of other cities and incorporated villages may limit the speed of motor vehicles, provided the rate is not less than a mile in 4 minutes. The maintenance of a greater rate of speed for one-eighth of a mile shall be presumptive evidence of unlawful driving. What was said previously in regard to the 30 miles limit may be said with equal reason to the *prima facie* speed clause here, but in order for a municipality or incorporated village to prescribe a lower rate of speed, signs must be posted, and the regulations must fix the punishment. Official copies of the ordinances must be filed with the Secretary of State 30 days before they take effect.

Chauffeurs must obtain an annual license, and are required to pay an annual fee of $5. The Secretary of State is to appoint examiners, who are to hold examinations at convenient places throughout the State. Chauffeurs must send a photograph with their applications, and the photograph must be taken at least 30 days prior to the filing of the application. The examination shall cover such questions concerning qualifications as the Secretary of State shall require. No chauffeur's license shall be issued to any person under 18 years of age. A chauffeur's badge is furnished and must be worn in a conspicuous place.

Registrations Expire on a Definite Date

All registrations of every character expire on January 31, 1911, and the fees up until that time are one-half of the annual fees provided in the law. Thereafter registrations expire annually.

For violating the speed law the maximum penalty of $100 is provided, and that is all. It is a misdemeanor to operate an automobile when intoxicated, and to run away after an accident and to refuse to stop and give the name and address of the operator is a felony, entailing severe punishment.

It is provided that a third or subsequent conviction of a chauffeur for violating the speed law, upon recommendation of the court, the Secretary of State shall forthwith revoke his license. This same punishment does not obtain in the case of any other person operating a motor vehicle.

The age limit for all operators, whether owners, operators, hirers or chauffeurs, is 18. Therefore, an owner may not register his automobile and receive a license to run it if he is under that age, but he can register the machine and employ a chauffeur to operate it, or allow an unlicensed stranger to use it.

The law goes into effect August 1, 1910, according to its expressed provisions, but it is enacted that applications for registration may be made, examinations held and number plates, license and badges issued at any time within 90 days prior to the time of the taking effect of the law. It is a serious question whether or not the whole law is valid, since it provides that it is to go into effect August 1st, and also gives 90 days in which those covered by the law may prepare themselves to comply with it. The Governor signed the law on June 2d, and there are not 90 days between that time and the first of August. That part of the law which allowed this 90 days is just as important as that part which says it shall go into effect August 1st, and if one is inconsistent with the other, it is very doubtful whether the law can go into effect August 1st, and if it cannot go into effect on that date there is no authority to put it into effect thereafter on any subsequent date.

No Autos in Roosevelt Parade

When Colonel Roosevelt comes home there will be no automobiles in line to receive him. At least there will be none in the parade, which will be an important part of the reception plans, according to a letter addressed by the secretary of Justice Gerard, who is in charge of the Reception Committee, to James M. Carples, representing the Licensed Automobile Dealers' Association.

Mr. Carples, on behalf of the association, had tendered some cars to the committee, and the following reply was received from the judge:

"Mr. Justice Gerard directs me to acknowledge receipt of your letter of May 11 in regard to your very patriotic offer of 60 automobiles for the reception of Colonel Roosevelt, and to express through the judge the appreciation of the entire Reception Committee for your most generous offer.

"I am very sorry to say that the committee in charge of the Roosevelt reception find that they will not be able to accept the use of these autos. Major-General Roe, in charge of the parade, does not think the automobile can go slow enough, and as he is in charge, the committee bows to his wishes to use carriages instead of automobiles.

"Assuring you of the appreciation of the Reception Committee, and regretting that the offer cannot be accepted, I am, respectfully yours,

"(Signed) JOHN J. MURPHY,
"Secretary to the Justice."

Coming Events in the Automobiling World

June 20-July 6....Detroit, Mich., Industrial Exposition, Detroit Board of Commerce.
Dec. 1............Chicago, Ill., First Annual Aeronautical Exhibition in the Coliseum.
Jan. 7-14, 1911...New York City, Madison Square Garden, Eleventh Annual Show, Pleasure Car Division, Association of Licensed Automobile Manufacturers.
Jan. 17-24, 1911..New York City, Madison Square Garden, Eleventh Annual Show, Commercial Division, A. L. A. M.
Feb. 13-25, 1911..Chicago Coliseum, Tenth Annual National Automobile Show, N. A. A. M.

Races, Hill-Climbs, Etc.

June 6-14........Atlanta, Ga., Reliability Run to New York City. New York Herald and Atlanta Journal.
June 7-11........Carolina Endurance Run.
June 10-11.......Fort Erie, Ont., Track Race Meet under management of Buffalo interests.
June 11..........Newark, N. J., Reliability Run, New Jersey Auto & Motor Club.
June 11..........Portland, Ore., Road-Races of Portland A. C.
June 11..........Wilkes-Barre, Pa., Annual Hill-Climb up Giants' Despair, Wilkes-Barre Automobile Club.
June 14-15.......New York, Reliability Run of Motor Contest Association.
June 14-30.......Cincinnati, Seventh Annual National Reliability Run for Glidden Trophy, Through the Southwest.
June 16-22.......Albany Automobile Club, Albany, N. Y., Sixth Annual Tour to Atlantic City and Return.
June 18..........Ossining, N. Y., Hill Climb of Upper Westchester Automobile Club.
June 18..........Baltimore Hill-Climb of Automobile Club of Maryland.
June 18..........Philadelphia, Race Meet, Quaker City Motor Club.
June 25..........Port Jefferson, Long Island, N. Y., Hill-Climbing Contest. Automobile Club of Port Jefferson.
June 25-26.......Roadability Run, Automobile Club of Philadelphia, to Lake Hopatcong, N. Y.
July 1-4.........Indianapolis, Ind., Track Meet. Cobe Trophy Race—Held on Speedway Track, Chicago Automobile Club.
July 1-10........Los Angeles, Cal., Road Carnival of Licensed Dealers.
July 2-4.........Los Angeles, Cal., Speedway Meet.
July 2-4.........Wildwood, N. J., North Wildwood Automobile Club, Speedway Races and Club Run.
July 4...........Auburn, N. Y., Hill Climb of Automobile Club of Auburn.
July 4...........Cheyenne, Wyo., Track Meet of Cheyenne Motor Club.
July 4...........Dallas, Tex., Track Meet of Dallas A. C.
July 4...........St. Paul, Track Meet of Minnesota State Automobile Association.
July 11..........Plainfield, N. J., Hill Climb of Plainfield Automobile Club.
July, Middle of...Richfield Springs, N. Y., Hill Climb.
July, Middle of...Grand Rapids, Mich., Road Race of Grand Rapids Automobile Club.
July 18-23.......Milwaukee, Wis., Tour of Wisconsin State Automobile Association for Milwaukee Sentinel Trophy.
July 30..........Wildwood, N. J., North Wildwood Automobile Club, Speedway Races and Club Run.
Aug. 1...........Minneapolis, Minn., Reliability Run of Minneapolis Automobile Club.
Aug. 3-5.........Galveston, Tex., Beach Races, Galveston Automobile Club.
Aug. 4...........Algonquin, Ill., Annual Hill Climb of Chicago Motor Club.
Aug. 15..........Start of Munsey Tour.
Aug. 17..........Cheyenne, Wyo., Track Meet.
Aug. 31..........Minnesota State Automobile Association's Reliability Run.
Sept. 2-5........Indianapolis, Ind., Speedway Meet.
Sept. 3-5........Wildwood, N. J., Reliability Run and Speedway Labor Day Race Meet of North Wildwood Automobile Club.
Sept. 5..........Wildwood, N. J., Track Meet.
Sept. 5..........Cheyenne, Wyo., Track Meet.
Sept. 5..........Denver, Col., Road Race, Denver Motor Club.
Sept. 5..........Los Angeles, Cal., Speedway Meet.
Sept. 5-10.......Minneapolis, Minn., Track Meet at State Fair.
Sept. 9-10.......Providence, R. I., Track Meet.
Sept. 10.........Los Angeles, Cal., Mount Baldy Road Race.
Sept. 10-12......Seattle Wash., Race Meet.
Sept. 17.........Syracuse, N. Y., Track Meet of Automobile Club of Syracuse, Syracuse Automobile Dealers' Association and the New York State Fair Association.
Sept.............Chicago, Commercial Car Reliability Contest of Chicago Automobile Club.
Oct. 1...........Long Island Motor Parkway, Vanderbilt Cup Race, Wheatley and Massapequa Sweepstakes.
Oct. 3...........Louisville, Ky., Reliability Run, Louisville Automobile Club.
Oct. 6-8.........Santa Anna, Cal., Track Meet.
Oct. 7-8.........Los Angeles, Cal., Speedway Meet.
Oct. 8...........Philadelphia, Fairmount Park Race, Quaker City Motor Club.
Oct. 15..........Long Island Motor Parkway, Grand Prize, Automobile Club of America.
Oct. 16-18.......Chicago, Ill., Chicago Motor Club's 1,000-Mile Reliability Run.
Oct. 20-22.......Atlanta, Ga., Speedway Meet.
Oct. 23..........San Francisco, Cal., Road Race, Portola Cup.
Oct. 27-29.......Dallas, Tex., Track Meet.
Nov. 5-6.........New Orleans, La., Track Meet.
Nov. 6-9-13......San Antonio, Tex., Track Meet.

Foreign Shows and Races.

May 1-Oct. 1.....Vienna, Austria-Hungary, Automobile and Aviation Exposition.
May 28-June 9...St. Petersburg, Russia, Automobile Exposition.
June 13-18.......Scotland, Scottish Reliability Trials.
June 20..........French Voiturette Race.
June 21..........French Stock-Car Race.
June 22-July 5....Russian Touring Competition, St. Petersburg to Moscow; also Commercial Vehicle Trials.
June 27..........Speed Trials at Kiev, Russia.
Aug. 1-Sept. 15...French Industrial Vehicle Trials.
Oct. 15-Nov. 2....Paris, France, Aeronautical Society Show.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

THERE never was a time when the farmers could do without roads, and that they exhibit rare patience with the kind which are designated as bad, is true; but the day naturally comes when patience ceases to be a virtue, and it is apparently in evidence that the farmer is awakening to his opportunity now that the automobile is backing him up; it is a common cause. That the farmer is merely satisfied to have the assistance of the automobile maker in his fight for good roads is scarcely up to the level of belief; there is no better customer of the industry than the farmer, and that he is showing his customary good judgment is proven by the character of the automobile he selects for his own work.

The "Good Roads Tour," which is now winding its strenuous way between Atlanta and New York, is the handiwork of citizens of breadth, and a debt of gratitude is the proper due to the New York *Herald* and the Atlanta *Journal* for the excellence of the work undertaken; it represents valuable time, enterprise, administrative capacity, and liberality of policy. That this tour is needed as a missionary effort in favor of better communication is evinced by the illustrations of the roads in the South as they are depicted in THE AUTOMOBILE this week. It is these roads that the tourists will have to travel over, and while it is true that there are many stretches of fine macadam roadway in the South, even so, the illustrations talk for themselves. The impression they give is one that is known to every farmer. The roads are not nearly as good as they ought to be—they cannot be too good.

IT looks like a consignment of impertinence to take pains, and to incur a measure of cost, for the avowed purpose of teaching a novice how not to drive an automobile. On second thought there may be some virtue in this plan; it may bring a novice to a more complete realization of the fact that he should fight off his natural inclination on the ground that the natural way seems to be the wrong one. Philosophers have never taken the trouble to state why weeds grow in a garden without any cultivation at all, or why men have to learn to do the right thing in every walk in life. Perhaps it is for the same reason that the natural product of the soil is weeds. The act which is performed as a matter of habit requires no premeditation, and as difficult as it may be to point out the right way, it is a matter of small moment compared with the amount of effort which is demanded to awaken a victim from the force of his habit.

In view of a natural bent, considering well the tenacity with which the fangs of habit fasten to the thinking apparatus of man, it is not too much to say that there is a measure of reason in the process which has for its basis the awakening of the sense to the habitual wrong. It is a common saying that one cannot do two things at one time; if this is so, one is debarred from doing right during the period of following a natural bent in the wrong direction. With this underlying basis, it does not seem a far-fetched undertaking to more or less tersely point out how ruin can stare an autoist in the face; were he conscious it would scarcely be necessary to go to the pains; perhaps this process will awaken him.

✦ ✦ ✦

LUBRICATION has more to do with success in the maintenance of an automobile than the average man is likely to realize, and in view of its dual angle, there is an excellent chance for confusion of mind in dealing with this problem. One not accustomed to the situation might readily be led to the conclusion that quality of the lubricant is about all that has to be taken into account. All the lubricating oil on this mundane sphere would be as pearls to swine in the face of an ill-contrived mechanism placed for the purpose of feeding the lubricating oil to the zones which work under pressure, offer a hiding-place for the silt of the road, and squeak for want of a slippery surface when the oil fails to arrive on time.

In addition to the requisite quantity of a suitable grade of lubricating oil there must be an efficient conduit which will lead the oil from its storage tank to the surfaces which work under pressure and which have to be not only lubricated, but sealed so that dirt may not get in. Profuse lubrication accomplishes these ends, and the probabilities are that pressure is necessary if the work is to be well done. Just now this question of feeding lubricating oil under pressure is being agitated in the haunts of the automobile engineer, and there seems to be a decided tendency in favor of a definite means by which oil under a controlled pressure will be forced to travel from its lodging-place in a storage tank to the wearing surfaces which are so prone to manufacture food for serious reflection, if there is any uncertainty involved. Next to a suitable contrivance comes the quality of the lubricating oil; there is no need to state that it ought to be almost superlative, but there is occasion for saying that fraudulent substitutions should be carefully avoided.

Editorial High Lights Casting Reflections

WHEN an exhaust valve refuses to stay tight, the conventional recommendation is "grind it in"; but when an autoist follows this liberally provided free ad-vice until he gets wearied of grinding, he begins to won-der if he is not really barking up the wrong tree. The chances are that it would be more to the point to ascer-tain why the valve fails to stay ground in for a reason-able length of time. If the valve stem is but poorly re-lated to the head, which will be true if the fillet which joins them is considerably restricted, what the autoist needs is a new and properly fashioned valve; but if the water jacket, which is supposed to maintain an even tem-perature all around the seat, is stopped off by core sand in the foundry, what the autoist requires is a new cylin-der. Valve grinding is an occasional process with a good automobile motor, but it is a continual nuisance with the other kind.

✦ ✦ ✦

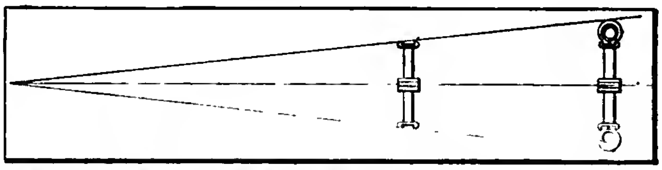
Noise is said to be the most annoying part of an auto-mobile; it creeps in at the invitation of age but slowly in a well-made car; but it has the unhappy knack of starting to wear out its welcome much too soon in the other kind. The man of experience defers the evil day and puts money in his pocket at a single stroke. His receipt is very simple; it calls for a liberal supply of good lubricating oil. When a car reaches the point in its life where noise becomes unbearable to the autoist of some discrimination, if the economy bug has a speaking ac-quaintance with him he will most likely make the mis-take of commissioning a repair man to take the noise out of the automobile. When his money takes wings and he finds himself alone with the repairman's ideas annexed to a worn-out car, he will most likely make the final discovery that noise is not eliminated by tacked-on innovations, although the chances of having additional trouble to cope with may have increased. The whole situation is portrayed in the simple statement, i. e., the prospect of parting with good money overcomes judg-ment, and blinds the victim to the unalterable fact he would never be able to induce himself, even by a money argument, to put up with an ill-behaved, noisy auto-mobile, nor is it likely that a repairman, even of some ambition, will be able to silence the crokings of a worn-out car—the right solution will be found in a new automobile.

✦ ✦ ✦

We hear so much about explosion in connection with the automobile motor as explosion stroke, explosion due to ignition, explosion pressure, and like expressions, which, when properly analyzed, are cast out as failing to present anything in accord with the facts, that it is not to be wondered at if autoists at large are imbued with the idea that gasoline is an explosive and will explode. It will be safe to conclude that nitro-glycerine is an explosive, but no amount of research will permit one to arrive at the conclusion that the relation of gasoline to nitro-glycerine is any nearer than that of a jungle lion to an inoffensive Mexican burro. Nitro-glycerine is explosive because it holds a large amount of energy per pound, and for the further reason that it evolves, in the process of burning, all the elements which are necessary for its complete combustion. Gasoline does not contain sufficient oxygen, either free or combined, to complete combustion; if it burns at all it must be supplied with oxygen sufficient for the purpose, and this oxygen must come from some other source. It is free in the air, and it is accepted therefrom when in the natural course the gasoline is utilized for its intended purpose. Under the circumstances, and in view of the controlling facts, the embryo autoist, whose fears are prone to overcome him, may accept gasoline as a fuel to be handled with impunity, unless he mixes it with a sufficient quantity of oxygen to produce carbonic acid and water, and applies a flame to start the fire. The word "explosion," in connection with gasoline, is noth-ing but a figure of speech.

✦ ✦ ✦

"Sea Island Cotton," as a statement, possesses a certain picturesqueness of language which carries conviction, particuarly when this fixed phrase is used in describing pneumatic tires. Its companion, "Para Rubber," has also a certain elevating sound, and it would be interest-ing to know to what extent Sea Island cotton and Para rubber are actually used in the building of pneumatic tires. It is understood that Sea Island cotton seed is used for the production of a certain high grade of cot-ton, and some of the German weavers of fabric use it in the production of the character of fabric which serves for automobile tire work. Departing from this phase of the problem for the time being, a certain curiosity leads one astray far enough to ask the average autoist if he thinks even Sea Island cotton fabric will stand up if the tires are run flat. Even if the tires are inflated, it does not necessarily follow that they are all so "blown up" that the diameters of the four wheels will be the same. A child would know that a cone-shaped spool, instead of rolling straight ahead, will describe a circular arc. If the tires on the four wheels are not blown up so as to result in equal diameter of all the wheels, they, too, will describe a circular arc in so far as their relation to the chassis will permit, and even if they are restrained, there will be sufficient disalignment to enormously reduce the life of the tires. To the man who wants to reduce the cost of tire maintenance it will be in the path of wisdom to stop dreaming about Sea Island cotton and Para rubber and go to work. The task which will have to be performed is represented in the simple process of inflating all of the tires so that they will sustain the weight to be borne, and making sure that the wheels be of one diameter.



Depicting the conical effect when one tire is well inflated and the other is more or less flat or removed from the rim

A Quiet Week in Detroit—A.L.A.M. Stirs Pudding

Abbott Claims Conspiracy to Stifle Trade

DETROIT, June 3—In the answer filed in the suit of the Columbia Motor Car Company, acting for the A. L. A. M., against the Abbott Motor Company, of this city, the latter company acting through its attorneys, Abbott & Abbott, Majestic Building, and associate counsel Offield, Towle, Graves & Offield, claims conspiracy to stifle competition, limit manufacture and sale of automobiles, and enhance profits of manufacturers operating under the Selden patent. This answer was filed yesterday by the Abbott company's attorneys and created quite a sensation.

More than this, the Abbott company claims that its own agents have been interfered with, and greatly hampered in making sales. The company asserts that the Selden patent has less than two and a half years to run and alleges: "That manifestly it is the intention and policy of the Columbia Motor Car Company and the Association of Licensed Automobile Manufacturers, who own and control its product, to bring suit under the patent and harass competitive manufacturers, compelling them to expend large sums of money in the courts."

Further, the company alleges that it is not the purpose of the complainant to bring these cases to trial, and petitions the court that the case be ordered to an immediate issue; also, that the complainant and the A. L. A. M. be restrained from threatening the Abbott company or its customers with further suits under the Selden patent, from in any manner hereafter interfering with agents or employees of the Abbott company, and from interfering with the credit of the Abbott company by letters, threats, etc.

A new point is made when the Abbott company asserts that the principal features of the Selden patent were disclosed in printed publications in this and foreign countries two years previous to the date of application for the Selden patent, and that the essential points thus became publicly known and were publicly used two years before the patent was asked for.

It denies the right of the company to bring suit against the Abbott company, charges Selden with postponing the issue of his patent for the "fraudulent purpose of extending the life of the letters when granted," and charges that he copied the ideas of other inventors. Further, it is claimed that the complainant company has no right to determine who shall have licenses under the patent, and charges that a large part of the fees received from such licenses are retained and used for the purpose of maintaining various committees known as: Price Committee, Trades Committee, Agency Control Committee, Association Patents Committee. The duties of these committees, the Abbott company claims, "consist solely in making arrangements and understandings whereby commerce between the various States and Territories and foreign nations in said automobile industry is sought to be controlled."

The answer was filed in the United States Circuit Court here yesterday.

News-Hunter Brings Down a Bag Full

Despite an unusually quiet week in Detroit, due, perhaps, to the long-continued bad weather, there was something going on during each and every one of the seven days just past. The biggest news items included the details of three new plants, one of them a mammoth steel plant, which would be of vast assistance to the industry as a whole. This was somewhat in the nature of a rumor, although well-known Chicago capitalists and steel men visited the city, inspected sites, and saw many local capitalists and business men. The men were A. W. Thomson and J. W. Alvord, both directors of the Inland Steel Company. While here they were entertained by Thomas H. Simpson, of the Michigan Malleable Iron Company, and George H. Barbour, of the Michigan Stove Works. Following closely upon their visit and the attending rumors, the Common Council took action with regard to the vacating of certain streets between Jefferson avenue West and the river, which makes it possible to have a clear tract of land there of between 14 and 18 acres, which can be increased to 20 acres by filling in to the river bank. The steel plant as projected was connected up to this city action. The location is an ideal one, near to the Detroit Iron & Steel Company's plant, while the Detroit Furnace Company is said to be seeking land in the vicinity. The Morgan & Wright factory is close by. Later, this rumor was denied, it being reported that the land in question was under option to Rogers, Brown & Company, who would erect an iron furnace. Either way, Detroit and the automobile industry will be the gainer.

The newly organized Grant & Wood Mfg. Co., of Detroit and Chelsea, in which A. O. Smith, of the A. O. Smith Company, of Milwaukee, Dr. J. B. Book, formerly of the E-M-F Company, Walter E. Flanders, president of the E-M-F Company, and others, are interested, announced the past week that they would embark in the manufacture of steel balls, in addition to the line of machine tools previously announced. This leads the company directly into the ball bearing business, bringing them into direct competition with other American bearing companies. With the strong E-M-F interests in the company, this move is taken to mean that the E-M-F cars for next year will be outfitted with the new ball bearings.

The two automobile plants to be announced will not be located in Detroit proper, one being for Port Huron and the other for Alpena. The latter city has accepted the proposition of C. H. Nunnelly and H. V. Grosbeck, of Mt. Clemens, and will furnish $20,000 in stock, a site, and a cash bonus of $50,000, while the promoters are to furnish $30,000. The car which will be built is to have a four-cylinder engine rated at 35 horsepower, runabout and similar bodies of three- or four-passenger capacity, and sell for $1,600.

Cass Motor Truck Locates at Port Huron

Out at Port Huron, the selected location of the Cass Motor Truck factory was announced. It is to be upon Lapeer avenue, and work has been started upon it. The company expects to give employment to 600 men at the start. The following directors have been selected for the company: John O. Turnbull, George Epstean, Frank B. Nichol and A. N. Spater, of Detroit; H. G. Barnum, Philip Higer and F. J. Haynes, of Port Huron.

Saginaw will be the scene of the next big operation of the General Motors Company, which has just announced that the sum of $800,000 will be spent upon the Jackson-Church-Wilcox plant there, where all General Motors steering gears are now being built. Some wonderment has been expressed at the action of Russell C. Durant, son of W. C. Durant, head of the General Motors Company, formerly Pacific Coast representative of the Anhut Motor Car Company, in suing that company for $5,000. This action was taken directly after a visit to his father to Flint. Young Durant claims that the $5,000 represents deposits on cars which were not delivered to him, and money spent in advertising. Being under age, Durant had to bring suit through a friend.

During the week, the Detroit-Dearborn Motor Car Company filed notice with the Secretary of State of an increase in its capitalization from $100,000 to $250,000.

A stockholders' meeting for June 15, in Jersey City, N. J., has been called by the United States Motor Company, to consider the advisability of increasing the capital stock from $8,000,000 common and preferred to $15,000,000 of each, making a total of $30,000,000. The common stock will be placed on a six per cent basis, July 1. As the fifth member of the executive committee, of the Detroit division of the United States Motor Company, John A. Boyle, general manager of the Briscoe Mfg. Co., has been selected. He has been connected with the Briscoe company since its formation, being one of Detroit's old hardware men. The other members of the executive committee are: Frank Briscoe, chairman; O. J. Mulford, vice-chairman; E. J. Corbett and Morris Grabowsky. E. [illegible] Martin is secretary for the committee.

Operators of automobiles for hire will not have such a cinch in the future as they have had in the past, according to a new ordinance, which the Corporation Counsel has been directed to draw up and which is nearly ready for action. When the taxicab regulation was drawn up, it was so worded as to apply only to automobiles equipped with a taximeter. This, coupled with some ambiguity in the wording, has allowed drivers of automobiles not fitted out with a taximeter to charge any fare they pleased, which they promptly did. The new ordinance is intended to remedy this defect.

The nearness of the State Fair, and the amount of advertising being given to it, in the way of advertising that the first showing of the 1911 models of automobiles will be made there, has done much toward booming the coming Industrial Exposition, to be held here June 20 to July 6, in which the automobile manufacturers and dealers have promised to participate. The latter are vitally interested, for the great influx of out-of-town visitors, particularly from the smaller towns, where agencies are not maintained, at this very seasonable time of the year, is expected to result in much business. The lighting plans for the exposition have been approved and the work is going on apace. It is intended to make this one of the big features of the show.

Owners of property along the Boulevard, Detroit's finest thoroughfare, have combined and formed an association, the object of which is to fight the further encroachment of garages, factories or unsightly driveways, which would make the drive as a whole less beautiful. The name of the association is the Boulevard Improvement Association, and they have already scored a signal victory in having the Common Council refuse permission for the building of several driveways, asked for by the Ford Motor Company, which is building an immense garage and salesroom on one of the prominent Boulevard corners. In this connection, it is said that the Packard Company is soon to follow in Ford's footsteps, the purchase of a large corner by Henry B. Joy being said to have this significance.

Dealers' Association Had a Beefsteak Dinner

Members of the Detroit Automobile Dealers' Association, more familiarly called DADA, were entertained at a beefsteak dinner by the Tivoli Brewing Company, at which it is said the refreshments partook more of a liquid nature than of solid.

Among those to join the colony across the river in their bid for Canadian business is the McCord Mfg. Co., which has just begun manufacturing operations in the new branch at Walkerville. A force of 60 men started work.

On Monday, a stock Flanders 20 roadster started from the factory for Quebec, there to start on a long trip to the City of Mexico. The intention is to show the ability of the little car to stand up nder any road conditions met with in the three countries, for which reason the tour has been named the "Under Three Flags Reliability." In the car are W. H. Lane, of the factory, as driver and pilot, and Paul H. Bruske, the new contest manager.

A very clever idea in the way of stopping speeding of automobiles in the State of Michigan has been evolved by the Secretary of State, who has sent out blanks to all townships and cities of the State, with a request that the names, addresses and other details of all persons who, within the past year, have been arrested for speed violations. It is the intention to compile this into a State blacklist, and have a copy on file in every city and township, so that as soon as a person is arrested for speeding, it will be possible to ascertain if he has ever been arrested for the same offense, and the details of the previous case. By keeping this record and list up to date, it is thought that justices will be able to inflict the proper fines, considering the previous record of the offender, and in this way reduce the amount of speeding.

Considerable dissatisfaction was expressed throughout automobile circles of this city over the actions of the A. A. A. Contest Board at the Indianapolis Speedway races of last week, and there is now considerable call for the rules pertaining to racing so that they may be read and understood. Even though not understood very generally now, the Contest Board is roundly condemned for the eleventh-hour decision, barring out cars which had been entered for some time, and whose appearance had been advertised and used as an attraction to draw people to the races. The Speedway management is not blamed for the incident.

The new plant of the Long Manufacturing Co. on Cass avenue, extending the entire block from Burrs to Amsterdam avenues, Detroit, Mich., is now ready for occupancy and in a few days will be running full blast. This plant is known as Long Factory No. 2, the main offices and principal factory remaining in Chicago, at 1430 to 1434 Michigan avenue. The Detroit plant is two stories and basement, 320 ft. on Cass avenue, by 145 ft. deep on Burrs and Amsterdam avenues. It contains over 100,000 ft. of floor space.

Overland Transcontinental at Chicago

In sixteen days of driving, eleven of which were rainy, Miss Blanche Stuart Scott and her companion, Miss Phillips, have reached Chicago in the "Lady Overland" car, en route from New York to San Francisco. The total distance traveled so far is 1987 miles. Only one mishap of any consequence has happened, and that one was not serious. The car slipped from the crown of a clay road during a rainstorm and cracked several spokes in one of the rear wheels.

Miss Scott was able to take the machine to a blacksmith's shop, where repairs were made under her supervision, and later the wheel was replaced. The iron band that was clamped upon the injured wheel, by order of Miss Scott, is shown herewith. The car and the young women show little effect of the trip thus far.

How the Overland's Battered Right Rear Wheel Was Stiffened

Makers Provide Cars in Brigades for Orphans

ORPHANS' DAY in New York City is noted for the good time the little ones experience, and there is no better way of indicating the attitude of the citizens of the Great Metropolis than to picture the situation as it obtains. It is a great misfortune that space will not permit of presenting the line-up of all the automobiles that were placed at the disposal of the Committee; it is not so much a question of limiting the amount of space which the presentation would take in THE AUTOMOBILE, but the whole paper would scarcely do the subject justice. That the matter should be dropped however, arguing that it is too formidable to handle, is far from the intention, and it is believed that the best way to indicate how well the makers of automobiles responded is to illustrate a few of the "brigades of automobiles" which were sent by the several concerns and their patrons.

Trucks Proved to Be of Great Utility Too

It is the general idea of the average citizen that a truck is a commercial affair, and that it is of no great use beyond toting a ton of coal, or "riding" groceries from the dock to the warehouse.

Possibly these good citizens will be surprised to find that some of New York's most precious possessions are able to experience a bushel of pleasure from using these trucks as substitutes for more elegant limousines and landaulets. The trucks behaved most generously; the orphans were well pleased, and it goes to show that things are not what they seem unless the mind is ripe to appreciate the true situation. Certainly the juveniles found the cushions soft and downy; to be sure the big-hearted drivers were well pleased with their cargo, and on the whole, when the whole situation is fittingly reviewed, the trucks were conspicuous features in the "Grand Review." Some of the makers went in big; they furnished all the pleasure automobiles they could collect together, and trucks were then called into play to fill in the gap. Fig. 1, as here presented, is of a White truck, which brought up the vanguard in supplemental relation to the "White Brigade," as shown in Fig. 3.

In like manner the Packard truck as shown in Fig. 5 was a companion to a long line of Packard automobiles. Then, there was an "Indian file" of Maxwell cars as shown in Fig. 2, not forgetting the Chalmers contingent as presented in Fig. 4.

Scattered along the line for a mile or more were the various makes of automobiles, some in large numbers, all to the extent that they could be commandeered for the occasion. There were cars as follows: Mora, Peerless, Rambler, Locomobile, Elkhart, Jackson, Matheson, Speedwell, Austin, Hupmobile, Croxton-Keeton, Regal, Herreshoff, Morse, Empire, Great Western, Knox, Midland, Parry, Fal-car, Ohio, National, Detroit Electric, Marmon, Woods Electric, Grout, Sebring, Mitchell, Cino, Selden, Chadwick, Cole, Stearns, Baker Electric, Standard, Haynes, Pierce-Racine, Pennsylvania, Patterson, Kissel-Kar, Winton, Cameron, Abbott-Detroit, Owen, Pullman, American, Thomas, Cartercar, Warren-Detroit, Studebaker, Inter-State, Corbin, Halladay, Waverly Electric, Columbus, and others.

It was a well-executed display of the magnanimity of the makers, backed to the limit by the agents and dealers, but the owners must not be forgotten; they were there, as many of them as could be assigned a place in the line, ready to do honor to the little guests who exhibited rare appreciation.

Louisville's Parentless Tots Entertained

LOUISVILLE, KY., June 6—More than 1,000 little orphans were made glad and given the time of their lives Saturday by the Louisville Automobile Club, who gave the little tots a free ride and a trip to Riverview Park. It was the annual outing of the club and the entertainment began at 1 o'clock in the afternoon, when scores of flag-bedecked automobiles went sailing down Broadway, after they had been loaded to the limit at the various orphanages in the city.

There was some disappointment on the part of Ben Watts and his committee in charge of arrangements, because of a heavy rain, but this did not dampen the spirits of the children. Following a long trip through the principal streets, the youngsters were taken to the park, which was turned over to them.

Reaching the northern entrance the big party was met by Col. Lum Simons, manager of the park. After the children had enjoyed the show at the vaudeville theatre they were treated to all of the cake, ice cream, candy and peanuts they could eat. Again the cars were filled with the Auto Club's little guests and once more the long procession was formed for the homeward trip. The rain had long since ceased and the children were given a taste of the original brand of joy ride as they were taken back to the various institutions.

The Louisville Automobile Club claims to be the originator of the orphans' outing about four years ago. It has been taken up by the different automobile organizations over the country, until now it has become almost a national affair.

Haradon Again Trade Association Head

In the short time that Wm. M. Haradon had occupied the presidency of the New York Automobile Trade Association, filling out the unexpired term of General Cutting, he has so impressed his fellow members, and the trade in general, with his aggressive spirit, and ability as an organizer, that little surprise was manifest at his being the unaimous choice of the association's stockholders, for re-election as the chief executive, at the annual meeting of the association, which was held at the Hotel Cumberland, Monday morning. C. W. Wurster, of Wyckoff, Church & Partridge, was re-elected first vice-president; W. W. Burke, of Carl H. Page & Co., second vice-president; W. H. Yule, of the B. F. Goodrich Company of New York, treasurer, and Walter R. Lee was re-elected secre-

Fig. 3—White Brigade was conspicuous in the line

tary and general manager for what will be his fourth consecutive term, C. Andrade, Jr., of the R. M. Owen Company, as counsel for the association, is also a director, with Messrs. W. A. Evans, of the American Locomotive Company; E. J. Harlam, of the Sagamore Garage Company; E. H. Broadwell of the Fisk Rubber Company; Peter Hoyt, of Hoyt & De Mallie Inc.; C. H. Larson of the Oldsmobile Company, of New York; W. C. Poertner, of the Poertner Motor Car Company, and A. J. Inderreiden of the Warner Instrument Company.

Of the 12 members of the board, 4 represent big garage interests, 4 are car dealers, and 4 are accessory manufacturers' representatives in this market. This arrangement will undoubtedly have a wonderful tendency toward materially harmonizing existing conditions between these three branches of the industry, and is the most potent argument the association has yet advanced in substantiation of its previously announced intention of regulating the retail selling, and garage business of this city, and exterminating many of the evils now existing, that have heretofore deterred good business men from risking capital in the proper development of this field.

Mr. Haradon announced his committee appointments at the meeting Monday. Interest centers chiefly in the Garage Committee, of which Synday B. Bowman has been made chairman; with him will be J. M. De Mallie of Hoyt & De Mallie Inc.; Benjamin Blumenthal, of the West End Auto Palace; Harry Strasbourger, of the Lenox Garage, and J. L. Joscelyn, of the Joscelyn Stable Company. The Accessory Committee will be made up of A. J. Inderreiden, of the Warner Instrument Company, chairman; Ernest H. Waterman, of the Hartford Suspension Company; E. R. Broadwell, of the Fisk Rubber Company; W. H. Yule, of the B. F. Goodrich Company of New York, and A. A. Hoffman, of the W. C. & P. Auto Supply House. W. C. Poertner, of the Poertner Motor Car Company, has been made chairman of the Contest Committee, with R. H. John-

Fig. 4—The Chalmers line-up was a parade in itself

ston, of the White Company, and C. H. Larson, of the Oldsmobile Company of New York, as his associates. The appointment of a Committee on Aviation shows the trend of the times. C. W. Wurster, of the W. C. & P. Company, who is probably the most enthusiastic and practical aeronaut in the city, has been named as chairman, while W. H. Yule, of the Goodrich Company, and A. J. Inderreiden, of the Warner Instrument Company, are his assistants.

Orphans' Day in Other Cities

The sixth annual Orphans' Day outing and picnic was observed in Pittsburg Wednesday, June 1, under the management of the Automobile Club of Pittsburg. Although the weather was very unfavorable, 135 cars were in line and over 800 children enjoyed the outing, twelve institutions taking part. The usual ride of about 25 miles around the parks and boulevards was broken by a stop at the Zoo. The afternoon was spent in Schenley Park, where luncheon was served.

Upwards of one thousand parentless little ones were the guests of the Quaker City Motor Club on June 8 at Willow Grove Park. Over 100 cars were donated by club members and the various local tradesmen, several of the Quaker City papers furnishing the lunch and the Rapid Transit Company donating the use of the park and its numerous attractions.

Arrangements for Orphans' Day, which will be held the latter part of June, under the auspices of the Columbus, Ohio, Automobile Club, are going on rapidly. It is proposed to give at least 2,000 children a picnic at the grounds of the country club.

General Motors Threatens to Cut Loose from A. A. A.

THINGS are sizzling in the affairs of automobile racing and contests. There is an electric quality in the air whenever the subject is mentioned where high officials are wont to gather, and the crop of rumors as well as semi-verified reports contain the promise of several interesting developments.

The most notable eddy in the current is the whirl that is centered over the General Motors Company and the A. A. A. as a result of recent happenings at Indianapolis, Worcester, New Haven and prospective happenings in the coming Glidden Tour. Cars made and entered in the first three named of these meetings by the Buick Motor Company and other subsidiaries of General Motors have not been allowed to go in stock car events.

According to an official statement of the General Motors Company, the trouble came to a head over the interpretation of the rules under which the recent Brighton Beach 24-hour race was run, although since then several added factors have become involved in the puzzle. While the question raised at the 24-hour race was one of minor importance, inasmuch as the car disqualified by the referee did not finish very prominently, the appeal from his ruling is still undecided by the Contest Board and may lay the foundation for future difficulty.

But the real breach happened at Indianapolis when the Buick 16A and 16B entries were barred from the stock car races along with several other varieties of motor cars with which the same fault was found by the officials.

According to the statement of the General Motors Company the disqualification was not made in proper form and was delivered to the entrants in the shape of an article published in the press. The grounds for disqualification were based upon the alleged intent of the rules to define a stock car as one that was included in a certain percentage of the type of cars that had already been manufactured prior to the entry of the car in the contest. According to the statement, sharp protest was made in vain to the referee and a bond was offered to cover all contingencies, but a revision of the ruling was denied.

The statement closes with a demand for an amendment of the rules or a different construction of them.

Following the difficulty at Indianapolis, the Buick cars which were subject to the ruling, the Warren-Detroit entry and others have had an interesting experience. At the Worcester hill climb last Saturday one of the Buicks, the Warren-Detroit and the "100" Model Buick were entered. An official decision barred the Buick entries from participation in the stock car events and something happened to the Warren-Detroit. As a result the Buicks were withdrawn from the free-for-alls. At New Haven hill climb, Tuesday, word was sent that the Buicks would not compete, although they were regularly entered.

When this last announcement had been made the report was circulated vigorously that the Buick racing team had been ordered to withdraw from all competition and its entries for the Wilkes-Barre hill climb were annulled.

A spirited colloquy occurred in the official stand at Indianapolis during the recent race meeting on the Speedway when W. C. Durant entered his protest against the disqualification of the cars. He was sharply critical in his position, with Chairman S. M. Butler, of the Contest Board, on the other end of the argument. The situation was exceedingly strained for a while, but was eventually soothed down to a certain extent.

On the other side of the affair, Chairman Butler had the following to say: "The work of the Contest Board is based fundamentally upon the exact definition of the stock car. The competition of specially built cars with those of manufacturers who comply with both the letter and the spirit of the rules would be manifestly unfair to the parties who obey the rules. All stock car contests depend absolutely upon the strict obedience to the rules. Either we can define a stock car and live up to our rules, or we have failed in our purpose.

"With relation to the trouble now developing as a result of our rulings at Indianapolis and elsewhere, I wish to state that the cars barred from the regular stock races did not come within the definition of stock cars under the rules. I understand that the General Motors Company intends to withdraw from competition and that it has ordered its entries scratched in all future events. This move may mean a new association is being planned. I distinctly told Mr. Durant at Indianapolis that I was not present to take abuse from anyone and that the cars barred by my order had not lost the right of being considered on appeal to the Contest Board. I assured him that if the ruling was based on error, the facts in the case could all be brought out in a perfectly legal manner under the rules."

W. C. Durant was not in town or available to get his views on the subject, but an official of the Buick Motor Company confirmed the report that its racing team had been ordered to withdraw from competition. As far as the entries of the General Motors companies are concerned in the Glidden Tour, he could shed no light as to the intentions of his concern.

Chairman Butler, however, said: "There has been some acrimony concerning these entries. So far we have received no definite instructions as to the classes in which the cars are intended to go. For this reason, and as the list of competitors has already been arranged, I have instructed the officials to enter the two Buicks and the two Oaklands under the section to compete for the Glidden Trophy.

"If these cars are not presented and do not measure up to the specifications of the classes in which they have been entered they will be scratched."

Newark Club's Reliability Run

With an entry list of forty cars the reliability run of the New Jersey Automobile and Motor Club, which will be held Saturday, June 11, promises to be one of the most interesting events of New Jersey motordom for the year.

The course as laid out will be 145.1 miles and the cars will go over it twice during the day. The roads are varied, as has been detailed in previous issues of THE AUTOMOBILE, and they have been selected with the idea of giving the entered cars a thorough road test.

The start will be from the club house on Park avenue, Newark, at 5 o'clock in the morning and it is expected that the contestants will finish about 8 o'clock in the evening. Everything points to a strenuous time on the part of the contestants, and the result should benefit the industry.

Maine's First Real Hill Climb

PORTLAND, ME., June 6—Automobile contests have been inaugurated at last in Maine, and a typical hill climb was held Saturday, in which fifteen cars took part. So successful was the affair that it is likely to be an annual feature. The Sunday *Telegram* fathered the event.

Eight contests were run off and good time was made. The course was laid out on Blackstrap Hill, about six miles from this city. Three Buicks won first honors in their classes, and a Ford, Palmer-Singer and Inter-State also won. The entries were limited to stock cars and the drivers were all residents of Cumberland County.

The racing committee consisted of the following: F. A. Nickerson, William Taylor, H. F. Merrill, D. W. Hoegg, Jr., and A. G. Frost.

"Perkins Pays the Freight"—Be Discriminating

By HAROLD O. SMITH, President Premier Motor Mfg. Company.

CONTESTS present a very interesting and live subject for those who are connected with the manufacture or use of automobiles, and for others who are interested because of the fascination, and instructed because of what the contests tell, and enlightened because they pay the bills. It is a startling fact to state to a customer in the purchase of any car that the selling price must necessarily include a certain amount of material, a certain amount of labor, and a certain amount of other items classed as expense because they do not represent either labor or material. But it is also true that every item of expense enters into the cost of the motor car upon which the selling price is based.

Yet, it cannot be said that this is an unjust charge, and possibly the money spent in certain contests, tests, or proving-out, may be the cheapest of all the items charged against the production of the machine. For example, if the expenditure of a small amount revealed unsatisfactory features, or proved what was the most unsatisfactory, the cost of finding this out might be the price of a good and satisfactory car, as against an unsatisfactory or unreliable one.

As an illustration, in a product which is a combination of a number of chemicals, no one would consider presenting to the public, without preliminary tests, an article which must be a harmonious combination to be successful. Motor car contests correspond to those chemical tests, and a motor car must be a homogeneous unit, for its parts must be so designed and proportioned as to work in absolute harmony. Just one unsatisfactory feature may make an unsatisfactory machine, and contests have aided in the development and rapid progress in eliminating undesirable features. In the early days racing proved the quickest means of securing the required experience, though what was called racing eight or ten years ago would be thought a tame affair to-day.

Speed on specially surfaced courses produces abnormal results, subjecting a few parts to unusual strains, while the general construction is probably not tested as much as would be the case in a touring car under ordinary touring conditions covering an equal number of miles. There was a time when frequent mechanical mishaps, delays and road repairs were not only tolerated but expected, but that is past and the public demands cars which can be depended upon to perform on the road in the layman's hands with certainty.

Speed contests and hill-climbs are interesting and more or less instructive, but the conditions are obviously abnormal, while with touring reliability events the conditions most nearly approximate road use, and reflect in a very telling way the results which may be expected of the cars in the service of owners. For example, the Glidden Tour of 1909 required the cars to travel a distance of 2643 miles from Detroit to Minneapolis, Denver and Kansas City, and the schedule required the contestants to cover a mile in every three minutes of time upon the road between those widely separated points, without making adjustments except in a few cases. That a few cars went through without replacements or adjustments reflects in a wonderful way the reliability, simplicity, and durability of the American car, as well as its ability to perform satisfactorily; but still more wonderful was the showing when the same machines were subjected to the technical examination. They were charged for every derangement, loose or lost nut, bolt, or screw, and yet the penalties upon some cars represented almost nothing. This in spite of the fact that there are between three and four thousand different parts in every automobile.

These conditions were the nearest approach to those of regular touring, being over the public highways, and duplicates of the usual touring conditions except that the word "strenuous" should be added. The difference between the results of speed and reliability contests as a criterion in the purchase of an automobile might be summed up in the statement that in the former it is not always the car in the best condition which finishes first.

No Clean Scores in the St. Louis Run

ST. LOUIS, June 6—The St. Louis Automobile Club could hardly have selected a worse day for its third annual reliability run, held last Saturday. The run began in a drenching rain and finished in mud, much of the way up to the hubs. Only twenty cars started, and but twelve finished.

F. H. Semple, driving a Locomobile, was declared the winner of the Hagerman Cup offered for the car making the most nearly perfect score in Class A, touring cars. Samuel J. Pingree was awarded the Class B prize, the Plant-Walsh Cup. He drove a Chalmers. Semple's score was 967, and Pingree's 997. Not a perfect score was made. In addition to the contestants there were the press car, a Marmon, driven by Herman Schnure; a Franklin, driven by W. E. Brearley, for officials, and a half-dozen other non-contesting cars.

The Marmon car driven by A. R. Byrd, Jr., suffered a broken driving shaft and had to drop out at Eureka. Wall's Stearns car caught fire twice en route, and mud was used to extinguish the blaze in each instance. Miss Ada Britton, Pope-Toledo, the only woman driver in the contest, dropped out at the first control.

The run was over a circular route from St. Louis through St. Louis and Jefferson counties and return. The distance was 109.1 miles. Under ordinary circumstances the road for the greater part of the way would have been almost perfect. Early Saturday, however, rain began to fall in torrents, and continued until after noon. By that time the country roads had become softened, and it was a fight through mud, and, in many places overflow from swollen streams.

The distance and time required were as follows: First control, Fenton, Mo., 17.7 miles, 65 minutes; second control, Byrnesville, 17.6 miles, 58 minutes; third control, Cond, 18.6 miles, 85 minutes; fourth control, Creve Cœur, 21 miles, 62 minutes; fifth control, Florissant, Mo., 21.5 miles, 63 minutes; sixth control, King's Highway and Forest Park boulevard, 12.5 miles, 45 minutes. Total number of miles, 108.9. Total time allowed, 358 minutes. The summary:

ENTRANTS IN CLASS A

No. Name of Car	Entrant	Standing
6—Locomobile	F. H. Semle	967
9—Matheson	R. L. Smith	964
28—Cadillac	John H. Flachmann	944
24—Cadillac	F. H. Pingree	938
21—Cadillac	A. A. Kelly	927
7—Marmon	W. A. Meletio	902
5—Mitchell	C. M. Barnard	872
35—Locomobile	C. H. Albers	869

23—Buick	W. H. Boehmer	...

Good Roads

(*Continued from page* 1035.)

erected, some of which were improvised out of farm wagons, others in divers hasty ways, but they were all decorated and occupied, the ladies in their best, the children in Sunday garb, all provided with ammunition in the form of flowers with which they pelted the participants of the contesting automobiles as they trailed along, maintaining a fixed alignment, and gracefully accepting the tribute, entering into the spirit of the occasion.

The noon control was at Spartansburg, N. C., where the tourists were given a magnificent reception, and a luncheon was tendered on the grounds of Converse College, which is the most noted girls' educational institution in the South. The privilege of the Spar City Club was extended to each of the contestants as the respective cars entered the grounds; the evidence of privilege was in the form of an embellished card. As a further evidence of the welcome offered, fifteen automobiles, holding the leading citizens of Spartansburg, with Mayor J. Boyce Lee, Hon. Charles O. Hearon of the National Highway Commission, Hon. T. J. Harris, Jr., and Victory Montgomery in the leading car, met the tourists at Greer, made them welcome in brief but fitting speech, and escorted them to the college grounds.

The general committee of entertainment included Mrs. A. W. Smith (chairman), Mrs. V. M. Montgomery, Mrs. J. W. Simpson, Mrs. Warren Dupre, and Mrs. C. H. Henry. The general committee was staunchly supported by the ladies who presided over the tables. It will be remembered that a luncheon was tendered the tourists a year ago under substantially the same conditions, so that the affair on this occasion was particularly enjoyable.

Cordial greetings were extended by the citizens of Gaffney, Blacksburg, and Gastonia. When the head of the line reached the main street of Gastonia it was confronted by a galaxy comprising a hundred pretty girls, all dressed in white, and waving small American flags; the town was decorated as befitted the occasion, and a sign stretched across the main street bearing the words "Speed Limit 25 Miles an Hour—Run As You Like, Our Motto." McAdenville, a thriving industrial center on the approach to Charlotte, closed down its mills during the passing of the paraded cars, and the citizens gathered en masse to witness the passing of the automobiles. Likewise, at Kings Mountain, and in fine, at every village on the wayside, decorations were profuse and appropriate, and the citizens made a holiday of the occasion.

What the Tourists Encountered on the Second Day

On the second day, from Anderson, S. C., the first car left at 7.30 a. m. The roads to Spartansburg, the noon control, a total distance of 67.3 miles from Anderson, were in very good condition, and the tourists found no trouble to get there on schedule. After leaving Spartansburg and passing through the towns of Cowpens, Gaffney and Blacksburg, the tourists crossed the State line into North Carolina, the distance being 103.8 miles from Anderson.

The roads in North Carolina were the worst so far on the tour, being full of treacherous holes and bad turns, and in many places it was necessary for the cars to carry chains in order to pull through mud holes resulting from the recent rains. About 25 miles out the travelers struck a fine macadam road which carried them into Charlotte, a total distance of 156.6 miles for the day's run. All of the cars finished the day's run in perfect running condition with the exception of one car, a Stevens-Duryea, No. 63. There were seven cars penalized in to-day's run, as follows: No. 21, Pope-Hartford, 17 points; No. 29, Stoddard-Dayton, 48 points; No. 39, Selden, 17 points; No. 43, Maxwell, 164 points: No. 48, Ohio, 108 points; No. 55, Ohio, 48 points; No. 69, Columbia, 20 points.

The running time for to-morrow, June 8, from Charlotte, N. C., to Martinsville, Va., a distance of 145.6 miles, is 9 hours for Classes 4, 5, 6 and 7; 9 hours 54 minutes for Classes 2 and 3, and 10 hours 48 minutes for Class 1. The running time for the third day will be the same as the first two days of the tour, with one hour added for noon and luncheon control at Winston-Salem. The additional penalties for cars on the first day's run, June 6, are as follows: No. 47, Pullman, 304 points; No. 44, Velie, 688 points.

There are eight official cars in the tour: a White Steamer, 40 horsepower, carrying Major John S. Cohen, of the Atlanta *Journal*, and Hamilton Peltz, the manager of the tour; Ray M. Owens in Reo Pilot; Columbia carrying Referee Charles Jerome Edwards, and other officers; a Pierce-Arrow carrying James R. Gray, owner of the Atlanta *Journal*, and his family; a Lozier car with tires; a Welch-Detroit carrying Alex Schwalbach of New York, secretary and starter, and a White gasoline car carrying the Technical Committee.

Dead Horse Hill's Record Still Stands

(*Continued from page* 1037.)

cester Automobile Club are as follows: Daniel F. Gay, president; Chester E. Greene, vice-president; Henry F. Blanchard, secretary, and Milton C. Snyder, treasurer. The summary:

CLASS A—Open to any gasoline motor car (other than motor cars with solid tires, wheels 36 inches in diameter and over) which complies with the definition "stock car." This class ran in the following divisions:

No. Car	Driver	Time
	Event 1A—$4,000 and over	
1—Thomas Flyer	John J. Kingsley	1:06 4-10
	Event 2A—$3,001 to $4,000	
1—Stearns	R. H. Higgins	1:58
	Event 3A—$2,001 to $3,000	
1—Atlas	Elmer G. Knox	1:31 2-10
	Event 4A—$1,601 to $2,000	
1—Jackson	R. M. Lovejoy	1:10 9-10
2—Oakland Roadster	Howard A. Bauer	1:30 8-10
	Event 5A—$1,201 to $1,600	
1—Cameron	E. S. Cameron	1:38 6-10
2—Parry	Eddie Ditteau	1:56 7-10
	Event 6A—$801 to $1,200	
1—Cameron	F. F. Cameron	1:33 9-10
2—Oakland	Howard A. Bauer	1:43
3—Maxwell	Martin Dorley	1:47 1-10
4—Buick	Duncan Hooker	2:24 6-10
	Event 7A—$800 and under	
1—Cameron	Albert White	1:49 1-10
	Event 9—Free-for-All	
1—Fiat	Caleb S. Bragg	:58
2—Alco	Harry F. Grant	1:02
3—Jackson	R. M. Lovejoy	1:08 8-10
	Event 10—Amateur Event (Owners to drive)	
1—Stanley Steamer	Jay Clark, Jr.	1:09 9-10
2—Lancia	Nelson Slater	1:33 3-10

CLASS B—Open to any chassis of a gasoline car which is in accordance with the definition of a "stock chassis," to be governed by the following table of piston displacement and minimum chassis weight:

No. Car	Driver	Time
	Event 12B—161 to 230 cu. in., 1,400 lbs.	
1—Staver-Chicago	F. A. Wheelock	1:25 1-10

	Event 21—Exhibition Event, Stock cars, steam or electric	
1—Babcock Electric	F. A. Babcock, Jr.	2:00 9-10

Giant Crowd at Shingle Hill Climb

NEW HAVEN, June 8—Fully 50,000 persons witnessed the fourth annual hill climb of the Yale Automobile Club, yesterday, on Shingle Hill, near West Haven. Six automobile events, five of them for stock cars and one free-for-all, were carded. There was a very large attendance from out of town and in addition to many citizens of New Haven and surrounding cities, the college students were present in force.

The hill course is 5,320.50 feet long and is picturesquely located five miles west of this city. It consists of a series of rises, finishing with a gradient of 162 feet. About midway of the course there is a dangerous "S" curve cut through the rocky hillside. This had been much improved and straightened since last year, but still afforded an element of peril to the racers.

The timing device was simple but was not along the lines of the automatic arrangements that have been used elsewhere. The plan used involved the registration of the time by two officials.

The Yale Auto Club Committee which had charge of the climb was composed of: L. S. Cullen, chairman; C. D. Winslow, H. H. Logan, T. W. Case, John Hays Hammond, Jr., and W. A. Main.

The officials of the meeting were as follows: Referee, C. H. Gillette, president of the Hartford (Conn.) Auto Club; clerk of the course, C. D. Winslow; assistant clerks of course, L. S. Allen, D. B. Prentice, O. Jimenis, H. D. Matheson, R. N. Hall; starter, F. J. Wagner. Representative of the F. A. M., J. M. Boyce; timers, N. Young, C. Tenis, R. Page; judges, C. M. Robinson, counsel for New Haven Automobile Club, W. T. Dill, Paul S. Thompson, W. A. Main; telephone operators, R. K. Haas, R. Dougherty, R. Brown; chief of patrol, W. J. Ralston.

25 Entries in the

RICHMOND, VA., June 7—The entries for the Carolina Endurance Run, from Richmond, Va., to Raleigh, N. C., and return, were closed Wednesday night, June 1st, at midnight, and twenty-five contesting cars will take part in the second contest given by the *Times-Dispatch*, Richmond, in the interest of good roads in Virginia and North Carolina. As was the case in the Virginia Run, the American Automobile Association and the Richmond Automobile Club will furnish officers for the run, which will be under rules of these organizations.

Several of the contestants in the previous run did not enter the Carolina contest owing to the fact that no cars were available at several of the garages of the firms entering cars for the Virginia contest. F. E. Nichols, whose Reo won the sweepstake cup before, could not enter for this reason, while the Ford Motor Company made no entry on account of dissatisfaction with the ruling of the officials in the previous run. Miss Anne Dunlop, of Petersburg, the only lady contestant of the Virginia contest, will drive her car over the course, but not as a contestant.

The twenty-five cars entered will carry about eighty-five passengers, of whom about twenty-five will be wives and daughters of the contestants.

A meeting was held on Monday evening at which those taking part in the run were instructed by the referee. All cars were delivered to the technical committee for examination on Monday at noon, and were thoroughly gone over.

The route selected is a most picturesque one, a number of rivers being crossed and many places of historic interest passed. The road from Richmond to Petersburg is in splendid condition and after crossing the Appomattox River, through Petersburg and to the Greensville County line, fairly good roads are found, and when this is passed the best roads in Virginia are reached. The Roanoke River is crossed by a fine steel bridge, at Roanoke Rapids, a beautiful bit of natural scenery, and from here the road stretches like a white ribbon to Panacea Springs. The second day the roads are equally as good, the charming cities of Warrenton and Henderson being visited, as well as Wake Forest College and the Falls of the Neuse, the night being spent at Raleigh, N. C. On the third day the course will extend through Durham and on to Chapel Hill, where a brief stop will be made to allow a visit to the University of North Carolina.

The return to Durham is made over a fine stretch of macadam pike, and at that city Mayor Griswold will entertain the party with luncheon. Oxford will then be visited, and recrossing the Roanoke River the night will be spent at Clarkesville, where the entire population has extended an invitation of hospitality. The last day will include the old Boydton plank road, a unique stretch, Boydton, South Hill, Lawrenceville, Petersburg, and the return to Richmond, the cars reaching the starting point before 5 p. m.

Upon arrival of each car it will be turned over to the technical committee for examination and comparison, and with the reports of the observers, the judges will decide the awards.

The officials of the Carolina Run are as follows:

Dr. H. W. Bassett, referee; Otis M. Alfriend, A. A. A. representative; Robert B. Alport, chief observer; W. B. Nelson, timer and checker; Jonathan Bryan, pacemaker; Otis M. Alfriend, E. W. Farley and Dr. H. W. Bassett, technical committee.

Dr. Stuart McGuire will furnish the pilot car, and Car No. 3 will carry the officials.

Apropos of the forward impulse given the good roads cause by the Carolina run, reports from various points throughout the Old Diminion show much new road construction, which is welcome news to autoists.

In Washington County, the supervisors are planning to construct $200,000 worth of new roadway, beginning work this year,

Carolina Endurance

while adjoining, Washington County, just over the Tennessee line, Sullivan County is spending $300,000 for this purpose.

Greensville County, Va., will build twenty-eight miles of good roads, the contract being let at $1,200 per mile. Spottsylvania County will have over twenty-five miles under construction shortly, at a cost of about $1,750 per mile. Much of the new roads will be of macadam and gravel.

In Fairfax County, six miles of road will be put in first-class shape, and reports from many other points show marked improvements in the roads in almost every county in the State during this year.

Though the matter has not reached any definite proportions, autoists in this city are said to be talking over the holding of a show here. With the automobile so popular among almost all classes in the State, such a venture would no doubt prove a highly successful one.

OFFICIAL ENTRY LIST IN CAROLINA ENDURANCE RUN

No.	Cars.	Entrants.
1	OLDSMOBILE	Dr. Stuart McGuire
2	E-M-F	Jonathan Bryan
4	BUICK 17	T. E. Williams
5	REGAL	S. Stagg
6	RAMBLER 53	E. J. Allen
7	RAMBLER 54	E. J. Allen
8	RAMBLER 54	C. B. Richardson
9	BUICK 17	Foster Motor Car Co.
10	CHALMERS 30	E. L. Pelouse
11	CHALMERS 40	Dr. R. C. Bryan
12	CHALMERS 30	J. T. Palmatory
13	BUICK 17	Rufus Williams
14	OVERLAND	J. J. Tignor
15	OVERLAND	Dr. Benjamin A. Hord
16	MAXWELL	Dr. Samuel McAnally
17	OVERLAND	Dr. W. H. Parker
18	BUICK 17	J. R. Williams
19	WHITE	B. A. Blenner
20	OLDSMOBILE	B. A. Blenner
21	STEARNS	B. A. Blenner
22	OLDSMOBILE	J. J. Ballou
23	HUPMOBILE	Richmond Motor Co.
24	SPEEDWELL	Speedwell Motor Co.
25	HUDSON	E. D. Hotchkiss, Jr.

There are numerous and varied makes of autos visible on the streets of Richmond, Va., but among them the most noticeable by their number in their class are the Hupmobile and the Buick. Richmondites buying a small car almost invariably choose the former, while the latter appears in many different styles and sizes.

Two Protests in Worcester Climb

Protests have been filed with the Contest Board against the Jackson and Lancia entries, which performed so well in the recent Worcester hill climb. Discussing the matter, Chairman Butler said:

"The Jackson car, model 59, is shown in the catalogue of that company, stripped to its lowest terms. The contention is made that the car that took part in the stock car event answered the specifications of that model as contained in the certificate on file with this board and advertised by the company, and this technicality seems to bring it within the letter of the rules even if it was outside as far as the spirit is concerned.

"The Lancia car is made abroad and is sold f. o. b. New York in form similar to a stripped chassis.

Many Enter Wilkes-Barre Climb

Wilkes-Barre, Pa., June 6.—Entries for the fifth annual hill-climbing contest of the Wilkes-Barre Automobile Club have been coming in rapidly and the outlook is that there will be more cars and a greater number of famous drivers in the contest on Saturday, June 11, than for any of the previous events. The first entries were received from the Knox Automobile Company, which will have cars in the free-for-all, the event for the Hollenback Trophy, and for cars with a piston displacement of 301 to 450 cubic inches. Fred Belcher will drive them. The National "Forty" car has asked for entry blanks for the Hollenback Trophy, the free-for-all, for runabouts costing $3,000 to $4,000, and for runabouts costing $4,000 and over. The Houpt-Rockwell Car, Stanley Martin driver, has been entered in the free-for-all. The General Motors Company expects to enter cars in several events, and Louis Chevrolet will drive them. Other drivers who are expected to compete in the climb are Bruce Brown, who holds the record for the hill, made last year with a Benz; Ralph DePalma; Bragg, who has not yet tried the course; George Robertson, and others. The entries closed Monday, June 6, at midnight, with the secretary, P. S. Ridsdale.

The course is now in excellent shape, the water breaks have all been removed and replaced with underground drain pipes, and the cool damp weather has aided in packing the course until it is in fine condition. General C. B. Dougherty, Commander of the Third Brigade, N. G. P., will be in charge of the policing arrangements on the day of the climb and will have a large force of State constabulary on guard. The hill will be open for the contestants to practice on Wednesday, Thursday and Friday of this week, and special police will guard it.

"Munsey Historic Tour" Plans Under Way

Philadelphia, June 6—Plans for the 1910 Munsey tour are now well under way. The contest, which, by the way, will be officially entitled "The Munsey Historic Tour," will be run under Grades 2 and 4 of the A. A. A. rules—contestants in Grade 2 being penalized for time, road work, final operative tests and final technical examination, this group consisting of cars entered by manufacturers and agents; entrants under Grade 4 consisting for the most part of cars privately owned, but which will be compelled to follow the same route as the Grade 2 cars, with no supplementary tests or technical examination.

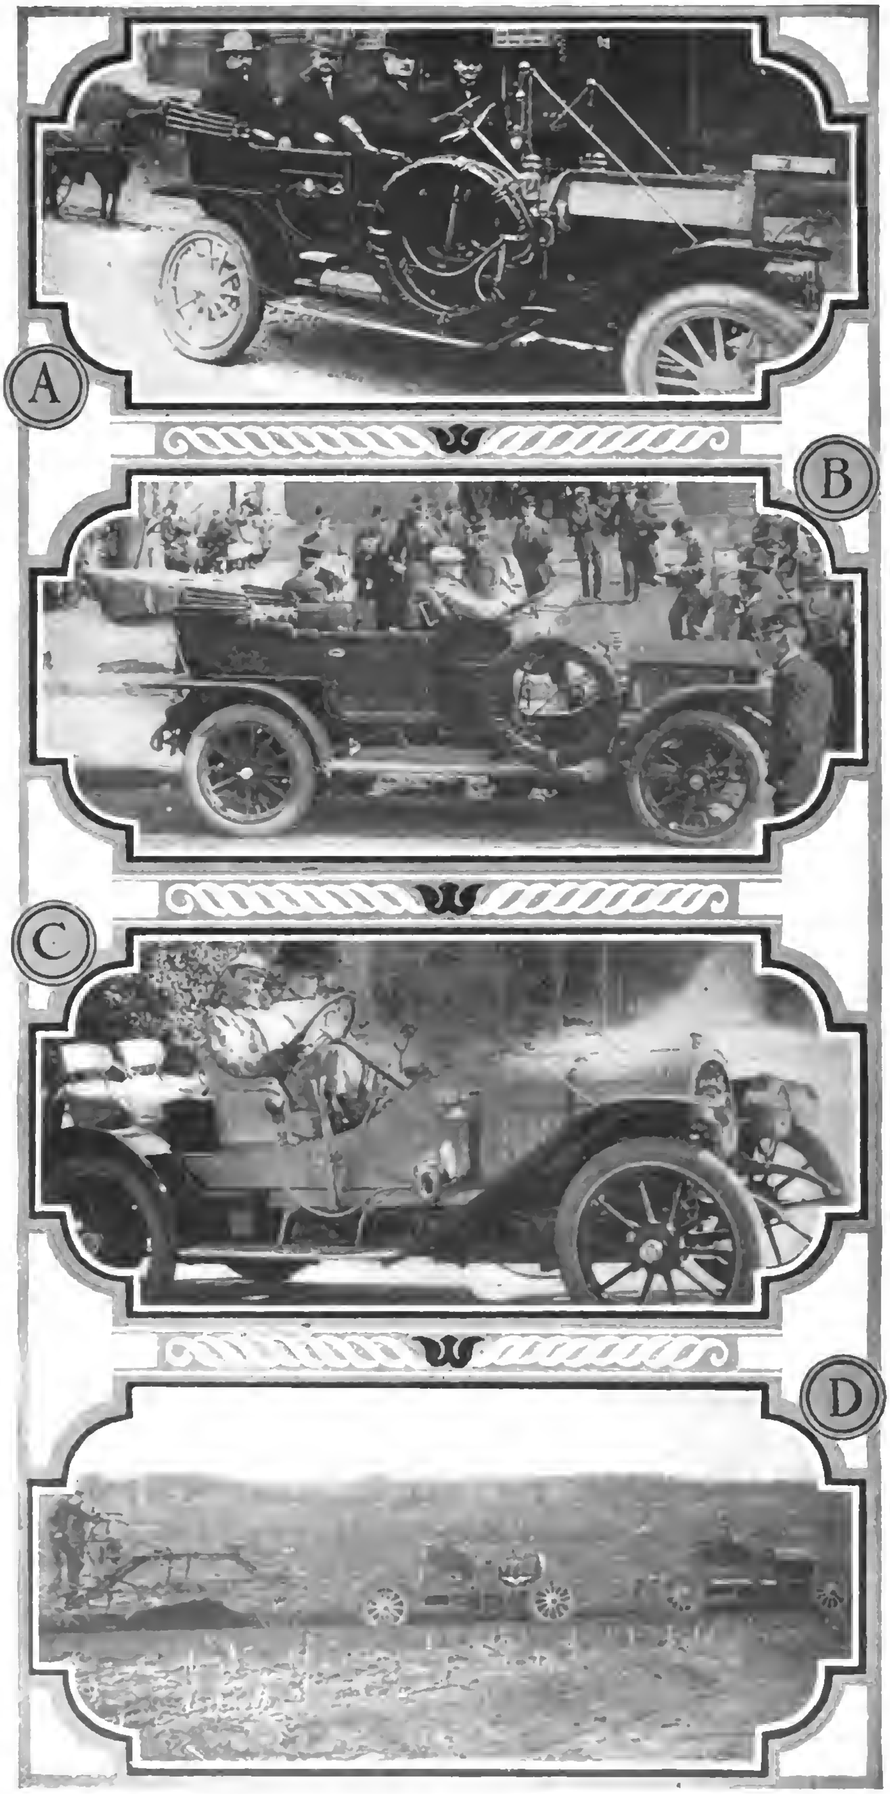
The tour will start from this city August 15, and end in Washington, D. C., two weeks later. The itinerary, as at present outlined (slight changes may be necessary where the pathfinders discover that hotel accommodations in summer resort towns may be inadequate), includes the following principal cities and towns: Philadelphia; Morristown, N. J.; West Point, N. Y.; Lenox, Mass.; New London, Conn.; Boston, Mass.; Portsmouth, N. H.; Portland, Me.; Plattsburg, N. Y.; Saratoga, N. Y.; Binghamton, N. Y.; Harrisburg, Pa.; Gettysburg, Pa.; Baltimore, Md., and Washington, D. C.—approximately 1,700 miles.

The historic feature of the run will doubtless appeal strongly to the tourists, such revolutionary landmarks as Independence Hall, Philadelphia; the battlefields of Trenton, Princeton, Morristown, Stony Point, Bunker Hill, Concord and other lesser conflicts being on the route; not to mention Gettysburg, Frederick and other fields of strife which will recall the terrible days of 1861-65. The pathfinder will start from this city June 15.

Experts Will Discuss Good Roads

Savannah, Ga., June 6—All is in readiness for the annual meeting of the Federation of Good Roads which will convene in Savannah Wednesday.

The sessions will be full of interest and will be held in the Guards' Hall, where talks on practical road-making will be the order of each day's session. Judge W. F. Eve is president.



A—Party of Omaha City Officials in Inter-State Car Inspecting the City
B—President Taft Going Home From Church in His White Steamer, Millbury, Mass.
C—Frank L. Chance, Famous Baseball Player, at the Wheel of His Pope-Hartford
D—Great Western Cars Pulling Plows in Work Near Indiana Factory

MAKING A DEMONSTRATION

(A) As exemplifying the widespread use of the automobile by municipalities and municipal officers the first picture shown is that of Omaha's mayor and chief of police in an Inter-State car. At the wheel is J. J. Donahue, chief of police of that thriving Western city, while the man beside him is the mayor, J. C. Dahlman, often spoken of as the "Cowboy Mayor." The other occupants of the car are George Rogers and C. J. Karbach, secretary of the fire and police commission. All three of the city officers shown are enthusiastic over the application of the automobile to many difficult problems of city administration.

(B) In marked contrast to all of his predecessors, President Taft has taken to the automobile not for isolated use, but for continuous and permanent use, availing himself of its help at any and all times. In this use, too, he shows considerable partiality to the White steamer, the picture showing him about to enter his White car at Millbury, Mass., upon the occasion of his recent visit there. The picture shows the Chief Executive leaving the Unitarian Church with his aunt, Miss Delia C. Torrey.

(C) Now, the baseball man is in the limelight, this being essentially his time of year, all of the major and minor leagues having just got fairly started. The picture shows one famous player who has taken to the automobile, Captain Frank L. Chance, manager, captain, and first baseman of the Chicago National League club, more familiarly known as "The Cubs." The car of Mr. Chance's choice, the one at which he handles the wheel, is a Pope-Hartford, purchased during the Winter at Los Angeles from the Pope agents there.

(D) In the modern scheme of testing out a car before calling it finished, nothing is too strenuous for the ubiquitous tester to tackle, nothing feazes him. Here is shown a pair of them, employed by the Great Western Automobile Company, Peru, Ind., helping out on some heavy plowing. The front machine is attached to the second by means of a chain while the rear automobile has a stout wire cable connecting it with the plow. This road work is excellent in two ways; it makes the roads better for other people, and it serves as a very good test-out for the cars.

The Carnegie Steel Company officials are going to have a tour through the Pittsburg district and the Mahoning and Shenango valleys. They will start from Pittsburg June 16 and will make a run to Bedford Springs, Pa., 120 miles and return.

In the Realm of the Makers

The American Dismountable Rim Company, of Cleveland, Ohio, was incorporated with an authorized capital of $50,000 by George B. Harris and others, to manufacture a patented automobile rim.

The Pierce Motor Company, of Racine, Wis., has completed its plans and specifications for 1911 Pierce-Racine cars. The first model will be issued about July 1. It is said that the 1911 car shows few changes over the 1910 car. The draftsmen and designer are now turning their attention to plans and specifications for 1912 cars.

The Cartercar Company, of Pontiac, Mich., has taken an option on several blocks of land adjoining its factory, and plans are now being made for extensive additions to the plant. The work will be pushed rapidly, and it is the intention to have the additions completed in time to begin turning out the 1911 models early in the Fall. It is expected that the additions will enable the output to be doubled in 1911.

The Federal Rubber Company has opened its own branch in Atlanta, Ga., at 170 Peachtree street, where will be carried a full and complete line of automobile tires and tubes of its manufacture, together with a full line of solid and truck tires, as well as its complete line of molded goods. This branch will be in charge of G. M. Seewald, late of the firm of Alexander Seewald Company, formerly local representatives of Morgan & Wright.

Branch managers of the Diamond Rubber Company recently held a conference in Akron. Among those who attended were: E. P. Weber, Boston; E. H. Fitch, Philadelphia; N. E. Oliver, Buffalo; L. K. Ritterhouse, Pittsburg; C. B. Myers, Cleveland; C. H. Smith, Chicago; W. E. Roby, Minneapolis; H. J. Lee, Atlanta; E. B. Tozier, Cincinnati; A. L. Gustin, Kansas City; H. J. Woodard, New York; J. G. Goudie, Detroit, and C. E. Matterson, San Francisco.

The Royal Rubber Company, one of the newer rubber plants of Akron, will soon start the erection of extensive additions to its plant, which occupies the old buildings of the Empire Mower & Reaper Company. The Royal company proposes to increase its output to include motorcycle and automobile tires. Up to the present time it has confined its output to druggists' supplies. O. C. Alling, of New York, is president of the company; J. H. Baird, New York, vice-president and superintendent; T. O. Evans, Akron, secretary, and J. C. Gibson, Akron, treasurer and general manager.

A by-law authorizing the sale of three and one-half acres of the recently acquired 20-acre factory site to the Regal Motor Company has been passed by the Windsor (Ont.) Council by a vote of 378 for and 21 against. The deal will be closed and the company will break ground for a plant.

O. H. Sebring, head of the Sebring Automobile Works, of Sebring, Ohio, has announced that a plant 500 feet long will be built in Sebring for the manufacture of the "Sebring Six." Mr. Sebring says the plant will employ 700 men and will cost $200,000.

The Middleby Automobile Company, of Reading, Pa., has recently completed extensive improvements to its factory, including a foundry, paint shop, upholstering and wood-working department. This means the employment of about fifty more men. The company is now turning out a large touring car, a toy tonneau, a single and double rumble and a surrey.

Nashville's first auto factory was assured by the taking out of a charter for the Southern Motor Works last week by officers of the company now at Jackson, and prominent Nashville capitalists. The capital stock of the new company is fixed at $400,000, and Exile Burkitt, of Jackson, has been elected president, A. H. Robinson, of Nashville, vice-president, and W. H. Collier, manager. The incorporators of the company are: A. H. Robinson, Exile Burkitt, Johnson Bransford, J. H. Ambrose, J. L. Wisdom, G. M. Neely, G. W. Killebrew, and J. W. Love. The old Phœnix cotton mill has been secured and will be fitted up for the factory. This work is already under way and early next month the removal of the machinery from Jackson will begin.

Doings in the Garage World

The Toledo Garage & Supply Company has opened a garage at 713 Jefferson avenue, Toledo, where in addition to doing a garage and supply business it will conduct a repair department.

The Krouse Motor Car Company, 317-321 North Broad street, Philadelphia, is the first concern to take advantage of the improved pavement on Market street and has just established a branch house on that thoroughfare at No. 615. William C. Chambers has been appointed manager.

The Weber Implement Company, the St. Louis agent for the Mitchell, has been appointed representative in Eastern Missouri and Southern Illinois for the Rapid truck. A garage will be maintained at 4921 Delmar boulevard, where a repair shop and truck maintenance department will be installed. J. E. Burton will have charge of the truck department.

The Whittaker Motor Car Company has changed its name to the American Garage Company, and is now installed in a pretentious garage at 5875-81 Delmar avenue, St. Louis. The building contains 15,700 square feet of floor space, and will accommodate 90 cars. In addition to the agency for the Everett "thirty" the company has obtained that of the Rambler. An electric charging plant will be maintained. The members of the firm are A. G. Whittaker and Ira L. Bell.

Among the Various Agencies

S. H. Marvel, 1607 Hunting Park avenue, Philadelphia, has been awarded the local agency for the Wisco, a Janesville, Wis., product.

George B. Clay and H. E. Browne have taken the Philadelphia agency for the Cameron car, with headquarters at 1318 Ridge avenue.

The Commercial Automobile Company has secured the agency for the Edison storage battery in St. Louis territory. The company will retain the agency for the Frayer-Miller truck.

C. S. Cummings, of the Seattle branch of the Metropolitan Motor Car Company, reports that he has secured the local agency for the "Lancia" car. This concern has recently added $5,000 of automobile accessories.

Harrington & Green, with temporary offices at 310 Odd Fellows' Temple, have just acquired the Philadelphia sales rights for the Firestone-Columbus. P. M. Green and E. Harrington constitute the new company.

The Gray Motor Car Company has taken the St. Louis agency for the Kline-Kar. W. Ashley Gray, the moving spirit of the company, formerly was connected with the Dorris company. He is maintaining offices in the Liggett Building.

George R. Dunville has been appointed to the agency in St. Louis of the Kisselkar. This agency formerly was held by the Acme Automobile Company, which has retired from business. Mr. Dunville is located at 502 South Seventh street.

THE HARRIS "SILENT SALESMAN"

To attract attention to its long-established and well-known product, the A. W. Harris Oil Company, of Providence, R. I., is giving away free to its dealers the excellent store and garage fixture illustrated

herewith. It is called the "Silent Salesman" counter display, and should prove of inestimable value to dealers in attracting attention to the Harris product. Dealers desiring to install this sale-provoker will be supplied on request.

Seen in the Show Window

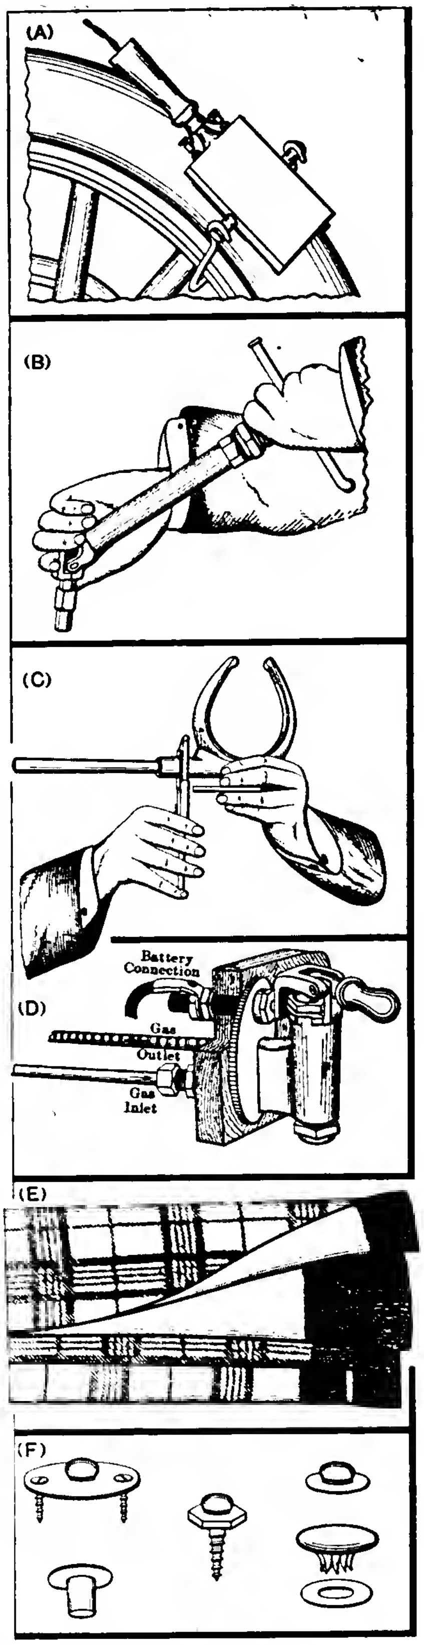
AWAKENING to the cost of tires, autoists are permitting themselves to study economy, and the ways of the wise. Among the things that help out in the battle for lower cost of maintenance is the vulcanizing equipment, which permits of healing the wounds of the tires before "mildew" chews up the fabric. The Auto "Eleck-Trick" Vulcanizer (Fig. A), made by James L. Gibney & Brothers, Philadelphia, Pa., is offered to that class of autoists who prefer to consult the interest of their own pocketbook rather than to call upon the makers of tires for advice when it is too late to do anything else about it.

This vulcanizer is operated on the electrical principle, uses either direct or alternating current, and the voltage is that which is used in electric lighting everywhere.

BEFORE starting out for an extended tour, it is in the path of wisdom to examine the tool kit to note if all the wrenches are present and accounted for. The "Auto Clé," with its ten possibilities, is so designed that it will handle that number of different sizes of hexagon heads of nuts, and they may be tightened up in any position. As a socket wrench, the one as here illustrated (see Fig. B) is recommended for its utility, and it may be had from dealers who make a point of looking after the interests of customers, but the safest plan is to have a set (they come in a mahogany case) in the tool kit.

COMMON prudence demands that an extra set of tires be taken along, and how to store them is a matter that sorely puzzles the average autoist not a little. Nelson S. Gotshell, Chicago, Ill., having struggled with this matter, finally solved the problem in the manner as here shown, and he now offers the "Non-Stop Adjustable Tire Carrier" (C) to those who appreciate the thief-proof properties of a secure tire carrier. It is made in black enamel, polished brass, and nickel finish, and is taking hold of the affections of the autoists who have the least trouble on the road.

DEMAND for a satisfactory gas lighting system has been long and persistent, and the Motor Specialties Company, Motor Mart, Boston, offers a solution of this problem which has the endorsement of the New Englander, who is noted for his acumen. The "Flash Auto-Lighter," as shown at D, comprises a dashboard equipment which is compact, good-looking and rugged. The connections for the gas and battery are all on the back, so that they are accessible under the hood, back of the motor, but they are protected from the weather and the tinker. The lights are turned on or off by a single movement using a lever, and the whole equipment is within easy reach of the man at the wheel.



(A) "Elec-Trick" Vulcanizer
(B) The Ten-Way "Auto-Cle"
(C) "Non-Stop Tire Carrier"
(D) The "Flash Auto-Lighter"
(E) N. O. B. Mills' Rubber-Lined Robes
(F) Usefuls for Home Auto Upholstery

EVERY autoist purchases his favorite car on a fine day, and he aims to take advantage of bright weather when he goes out for a ride. If he is caught in the rain it is possible that he will not be prepared for the worst. The Northern Ohio Blanket Mills, realizing that the sun will not shine all the time, make provision for inclement weather, and provide far-sighted autoists with all sorts of blankets and shawls, both warm and weather-proof, and in the many styles, one of which is here shown (E). Rubber lined robes are a prime favorite. They look well, keep out the wind, and last for years.

FOR the autoist who wants to do his own repair work to the upholstery of his automobile, or the body maker who deals in materials of this sort in a large way, the fasteners made by the United States Fastener Company, Boston, Mass., are offered in great variety, some of which are shown here (D). Many autoists, especially those who have a garage, a place for everything, and everything in its place, keep fasteners in one place; they come handy at an unexpected moment.

THE ease-loving automobile owner, who does his own driving, and yet balks at the job of pumping tires, will welcome the announcement of the Prest-O-Lite Company, of Indianapolis that they have perfected and placed on the market a new Prest-O-Tire tube, which in actual service has proven to be a veritable little giant in the filling of automobile tires. It is somewhat larger than the original type marketed by the company, carrying sufficient gas to satisfactorily inflate any of the larger size tires, above the 36 x 4, now coming into such general use. While this new Prest-O-Tire tube is a trifle bulkier than the early model, it is yet so small that a half-dozen tubes can easily be carried in a tool box, being only 1 5-8 inches in diameter and a foot long. The same puncturing valve can be used on both tire tubes, so that it is not necessary for a new valve to be purchased. It is sold upon the well-known Prest-O-Lite plan of exchange. That is, when exhausted it can be exchanged for a new one at almost any dealer's, merely by paying a small exchange fee, this scheme having proved eminently satisfactory in the company's Prest-O-Lite business.

THE AUTOMOBILE

Good Roads Tour Reaches New York

GAYLY decked with flags and streamers of all colors and bearing numerous evidences of their unusually hard experience on the long trip from Atlanta, sixty-five of the seventy-three original starters in the National Good Roads Tour, held under the auspices of the New York *Herald* and Atlanta *Journal*, swung past the reviewing car in front of the *Herald* building, Monday night, and were formally dismissed after being checked.

Many occupants of the cars still wore their travel-stained clothing, but a number had taken advantage of the stops along the way to refresh their appearance, especially the ladies, and at the finish of the long run they looked as if they had only motored from the City Hall. But the cars seemed like veterans just in from a hard campaign. Their official numbers and banners were awry and in other ways they showed the effects of their experience up in the mountains.

A STOP AS THE AUTOMOBILES ROUNDED A CURVE APPROACHING CHARLOTTE

Tourists Coming Into Winston-Salem

Natives View the Start from Spartansburg

But their motors were running smoothly and true and so far as their efficiency was concerned a large majority of the machines seemed perfectly capable of duplicating the trip without re-tuning.

Sixty-five of the original starters trundled past the finishing mark while eight cripples were left at various points en route, forced to yield to the exigencies of Jupiter Pluvius and accidents of the road.

The effect of such a tour cannot help but be an aid to good roadmaking throughout the country and especially in the sections traversed by the route of the tour.

The purpose of the enterprise was to foster and crystallize sentiment for good roads, the importance of which is universally recognized, and it is believed that the New York *Herald* and Atlanta *Journal* are combined in a fine effort.

The reception of the tourists at New York was conducted upon elaborate lines. The final day's run from Philadelphia was accomplished over excellent roads, the quality of which is reflected in the fact that 48 of the contesting cars had perfect road scores for that section of the trip.

The head of the column reached Perth Amboy ready to cross to Staten Island before noon, and the Richmond County Automobile Club was summoned in a hurry to act as escorts. It had not been thought that the tourists would arrive in this vicinity until later in the day, and the early appearance of the cars caused a lively scurrying among the club members.

The classification, running time and penalties follow:

CLASSIFICATION OF AUTOMOBILES WHICH WERE ENTERED

Class 1—Nos 20, 23, 31, 33 and 37.
Class 2—Nos. 7, 19, 22, 41, 43, 64 and 67.
Class 3—Nos. 8, 9, 10, 12, 14, 24, 50, 51, 53, 57 and 59.
Class 4—Nos. 16, 17, 28, 42, 44, 47, 48, 52, 55, 62 and 65.
Class 5—Nos. 2, 5, 15, 21, 25, 34, 35, 36, 39, 40, 46, 49, 56 and 69.
Class 6—Nos. 11, 13, 29, 38, 58 and 61.
Class 7—Nos. 1, 3, 4, 6, 30, 32, 45 and 63.
Non-Starters—Nos. 18, 26, 27, 54, 60, 66 and 68.

RUNNING TIME OF THE VARIOUS CLASSES OF CARS

June 6, 7 and 8—Classes 4, 5, 6 and 7, 9:00; classes 2 and 3, 9:54; class 1, 10:48.
June 9—Classes 4, 5, 6 and 7, 10:00; classes 2 and 3, 11:00; class 1, 12:00.
June 10—Classes 4, 5, 6 and 7, 11:00; classes 2 and 3, 12:06; class 1, 13:12.
June 11—Classes 4, 5, 6 and 7, 8:00; classes 2 and 3, 8:48; class 1, 9:36.
June 13—Classes 4, 5, 6 and 7, 4:30; classes 2 and 3, 4:57, class 1, 5:24.

Roads Were None Too Good En Route to Charlotte

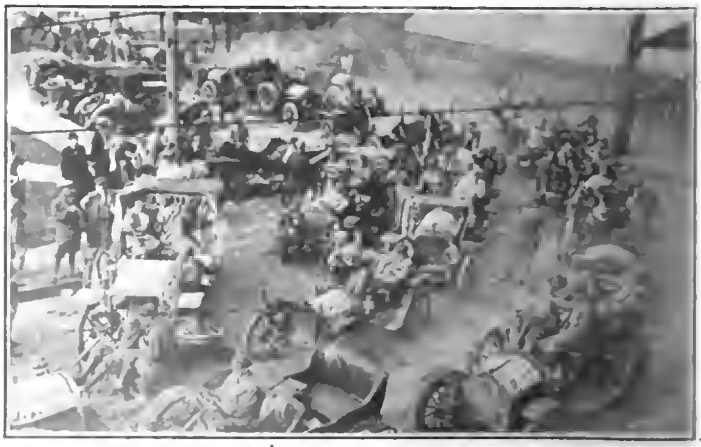
PENALTIES AS AWARDED FOR EACH DAY

June 6—No. 21, 50 points; No. 25, 43 points; No. 42, 77 points; No. 55, 12 points; No. 65, 77 points; No. 67, 193 points; No. 47, 304 points; No. 44, 688 points.

June 7—No. 21, 17 points; No. 29, 48 points; No. 39, 17 points; No. 43, 164 points; No. 48, 105 points; No. 55, 48 points; No. 69, 20 points; No. 44, 267 points; No. 55, 333 points.

June 8—No. 44, 2 points; No. 48, 175 points.

Pacemaker Calls Halt to Parade Into Spartansburg



Tourists Lined Up at Charlotte

Pacemaker Crossing Bridge Out of Charlotte, N. C.

Regal Checking In at Gettysburg

June 9—No. 2, 83 points; No. 3, 160 points; No. 4, 50 points; No. 11, 107 points; No. 12, 92 points; No. 14, 253 points; No. 15, 73 points; No. 16, 149 points; No. 17, 63 points; No. 20, 5 points; No. 22, 145 points; No. 24, 201 points; No. 25, 312 points; No. 31, 146 points; No. 34, 171 points; No. 35, 134 points; No. 36, 89 points; No. 38, 104 points, No. 40, 68 points; No. 45, 133 points; No. 46, 115 points; No. 48, 524 points; No. 52, 181 points; No.

A Noonday Halt Between Towns

56, 16 points; No. 58, 278 points; No. 61, 100 points; No. 62, 169 points; No. 65, 265 points.

The penalties as here given for June 9th have an allowance coming to them of 41 points, due to the fact that the judges were unable to get through on time, although it is true that they transferred their flag to 4 or 5 cars each time that they were stalled, and the difference in time, due to the delay, makes the 41 points which are to be subtracted from the points given.

The cars which came through on time, and have a clean score for June 9 are as follows: Nos. 13, 19, 30, 49, 53 and 57.

June 10—The cars which started and went through with a clean score for this date were Nos. 11, 13, 14, 15, 16, 17, 22, 25, 30, 34, 35, 38, 56, 62, 2, 3, 4, 6, 19, 20, 45, 46, 49, 53, 57, 61 and 65.

June 11—The cars which started and went through with a clean score were Nos. 2, 3, 4, 5, 8, 11, 13, 14, 15, 16, 17, 19, 22, 25, 27, 28, 29, 30, 31, 34, 35, 36, 38, 40, 45, 46, 49, 53, 56, 57, 61, 62, 63, 65, 24 and 28.

June 13—Points against cars which did not have clean scores were No. 21, Pope-Hartford, 32; No. 39, Selden, 74; No. 50, Cole, 1; No. 52, Oakland, 27; No. 69, Columbia, 12.

Checking Out at Martinsville

CHICAGO TROPHY TO BE WON BY THE BEST CAR IN THE RUNABOUT CLASS

CINCINNATI, O., June 15—Starting from here on June 14 and finishing at Chicago, Ill., on June 30, the Seventh Annual Reliability Tour Contest under the auspices of the A. A. A., for the Charles J. Glidden Trophy for touring cars, and the Chicago Trophy for runabouts and miniature tonneaus, with 38 cars in line, represented for the most part 1910 offerings, divided into 26 contestants and 12 automobiles marked "Official." Of the contestants there are 14 strugglers for the coveted Glidden Cup and 12 debaters for the Chicago Trophy. The names of the contesting cars in the respective divisions are as follows:

Automobiles Entered in the Chicago Trophy Class

No. 100, Moline; No 101; Moline; No. 102, Moline; No. 103, Lexington; No. 104, Cole; No. 105, Parry; No. 106, Falcar; No. 107, Maxwell; No. 108, Cartercar; No. 109, Cartercar; No. 110, Lexington; No. 111, Westcott.

Automobiles Entered in the Glidden Trophy Class

No. 1, Premier; No. 2, Premier; No. 3, Premier; No. 4, Chalmers; No. 5, Chalmers; No. 6, Cole; No. 7, Maxwell; No. 8, Cartercar; No. 9, Parry; No. 10, Glide; No. 11, Ohio; No. 12, Ohio; No. 14, Pennsylvania; No. 15, Cino.

Details Observed When the Cars Were Being Inspected

In general, the models entered for both trophies carry the vintage of 1910, and are of the same type as seen on the streets in the different cities every day. The three Moline entries for the Chicago trophy class are 1911 models, differing from Moline 1910 cars in that the stroke of the piston is longer than formerly, the cylinder sizes being 4 inches bore and 6 inches stroke. As a further advance over last year, the chassis frame is of the drop type. There are only two 6-cylinder cars in the contest, a Premier and a Pennsylvania, both Glidden contesters. All of the automobiles entered in the Chicago Trophy class are of the 4-cylinder type, excepting a 2-cylinder Cartercar, and it is worthy of particular note that this is the first time that a friction drive has competed for Glidden honors. All three Cartercars are fitted with the usual friction gearset which is so well known in the cars of this make.

Ignition is by magneto in every automobile entered for both prizes excepting for the 2-cylinder Cartercars. Among the types of magnetos employed, the Bosch system is on 9 of the contesting cars, 11 are fitted with Splitdorf magnetos, Remy has 2, Eisemann 1, and Kurtz carries 1. From the above it will be observed that this is a magneto year.

The fuel systems employed on the cars include 16 Schebler carbureter outfits on as many of the cars; the Mayer carbureter is on the 3 Chalmers contestants; the Maxwell cars have their own make, and the Stromberg carbureter is on two of the automobiles, and the rear guard is brought up with 1 Miller and 1 Brush.

It was in 1904 that the first annual run was started from New York and Boston and finished at St. Louis, covering 1,318 miles, counting from New York. In 1905 the tour began and ended in New York; its itinerary included Hartford, Bretton Woods, Concord, and Worcester. It was for this run that Charles J. Glidden put up the now famous Glidden Trophy, and it was awarded to Percy P. Pierce, driving a Pierce car, the distance being 871 miles. In 1906 the tour started at Buffalo, ran east through the principal cities in Central New York, north along the shores of Lake Champlain, and crossed the frontier line into Canada, swerved to the east from Montreal to Quebec, then south into Maine, finishing at Bretton Woods, a distance of 1,135 miles. In this tour, Percy P. Pierce defended his possession of the trophy with a Pierce car. As a second interesting part of the 1906 event, Paul H. Deming, chairman of the Touring Board, put up a trophy which was awarded to C. W. Kelsey driving a Maxwell car. In 1907 the tour started at Cleveland, ran west to Chicago, thence in an easterly direction, crossing the States of Indiana, Ohio, Pennsylvania, and Maryland, passed through Baltimore on its way to Philadelphia, and ended by crossing New Jersey to New York City, covering a distance of 1,570 miles. It was in this year that the deed of the Glidden Trophy was so changed that the award was made to the club whose team fin-

ITINERARY FOR THE 1910 TOURING CONTEST

Starting Dates A.M.	Starting Points	Intermediate Stops	Miles	Finishing Points	Day's Miles
June 14	Cincinnati	Lexington	83.3	Louisville	162.0

16 Running Days—average per day, 178.2 miles

ished with the greatest number of points to its credit. The Automobile Club of Buffalo was represented by 2 Pierce "Great-Arrows," 2 Thomas "Flyers," and 1 Packard.

In 1908 the tour started at Buffalo, ran south to Pittsburg, east to Philadelphia, north to Albany, east to Boston, north to the White Mountains, and south to Saratoga, covering 1,670 miles. The club teams for this year were the Buffalo Automobile Club No. 1, comprising 3 Pierce-Arrow cars, the Columbia Automobile Club team, comprising 3 Peerless cars, and the Chicago Motor Club team made up of 2 Haines cars and 1 Oldsmobile; the result was a tie. An attempt was made to wipe out the tie by running the cars from Saratoga to Syracuse to Buffalo, and then over the original course until all but one team was eliminated. The Buffalo team was at the starting line for the run the morning following the finish at Saratoga, but the other teams failed to show up, and the Buffalonians refused to cross the line. The cup, under the circumstances, could not be awarded, and it remained in the archives of the A. A. A. The 1909 tour started from Detroit, Mich., ran west to Chicago, north to Minneapolis, south to Council Bluffs, west to Denver, crossed Nebraska to Kansas City, covering a distance of 2,637 miles. In the meantime the Glidden Trophy deed of gift was amended so that it might be won by an individual, and it fell to the Pierce-Arrow entrant.

FACING THE TECHNICAL COMMITTEE AT CINCINNATI BEFORE THE START

Various Incidents of the First Day

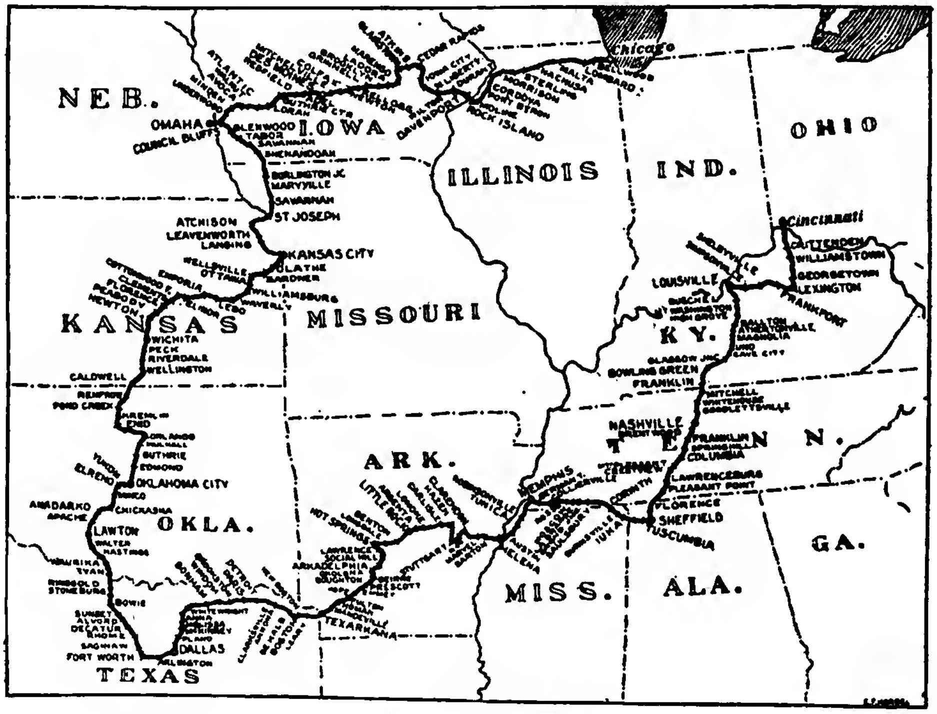
The four cars which lost out in the Glidden class were: No. 4, Chalmers, driven by Matson, by dropping a pin out of the emergency brake rod; No. 6, Cole, was fined 30 points for having to twice clean out the gasoline line to the carbureter; No. 9, Parry, which took on gasoline after leaving Lexington, and No. 14, Ohio, was given 22 points for taking on gasoline outside of a control, repairing water pump, and retiming magneto, which had to be done because a paper pin in the magneto shaft broke.

Those who lost out in the Chicago Trophy ranks were: No. 104, Cole, which, in trying to pass between a Moline car and an approaching horse vehicle, collided with the latter, breaking a wheel, which cost 1,042 points. The wheel was replaced by a new one which was procured from Louisville, and the work was so quickly done that the car covered lost ground and checked in on time; No. 106, Falcar, lost 60 points by having to put on a new magneto, a collar on the original one having slipped, putting the timing out and necessitating the replacement; No. 110, Lexington, lost 4 points for dropping a pin from the brake rod, which was replaced; and No. 111, Westcott, was burdened with 6 points for making two carbureter adjustments.

Interest Runs High Along the Route

It was the privilege of the tourists to admire the Blue Grass country around Lexington, to have a glimpse of the big stock farms with their whitewashed fences, colonial types of houses and to speculate on the witticisms of the local wags who sat on the fences and watched the automobiles go by. The colored folks straggled in from their haunts for quite a distance, and playing a subdued rôle, which is their part in the South, they were picturesque from the point of view of the tourists, which did not prevent them from presenting their own version of the affair.

From the crossing of the bridge to Covington, which took the tourists out of Ohio into Old Kentucky, was but a matter of a few minutes, and a Southern atmosphere surrounded the caravan at once. The roads were extremely good, taking them as a whole; piles of broken stone here and there along the way gave the impression that they were being maintained, and an occasional man engaged in breaking stone lent substance to the conclusion. The prognosticators of the party said that there must be a great many automobiles in Kentucky, and they based their conclusions on the behavior of the horses which were passed as the tour went on; the horses were not afraid of the automobiles, they were used to them.



MAP OF STATES AND PRINCIPAL CITIES THROUGH WHICH THE TOUR GOES

Wonderful View From Skyline Drive Near Canon City, Showing Mountains and Valleys

In Wonder House of Nature

By B. B. MORRIS

CANON CITY, COLO., June 13—Among the wonders of Colorado—that land where wonderful things seem ordinary in comparison with the superlative charms of the real attractions—is the Skyline drive, which threads the summit of the mountains adjacent to this city.

The roadway, smooth as a billiard table and thirty feet wide, is about 800 feet above the level of the bottom of the canon upon which the city stands and 8,000 feet above the level of the ocean.

Through the marvelously dry, clear air of Colorado, that sparkles and stimulates like bubbling wine, the view from the Skyline drive affords a series of pictures, excelled nowhere on earth. From the vantage point of the ridge the sight is unobstructed for miles, and looking out across the gorge the picture of the mountains, with their bases shrouded in purple shadows and their heads standing sharply into the eternal white, is inspiring enough to form the basis of the World's future masterpiece of painting.

One of the magnificent tours available for automobiles is one starting at Denver and passing through Colorado Springs. All the way southward on this leg of the journey, the tourist is in sight of the very backbone of the continent. From the spike-like points of Long's Peak, which lies back of Denver, to the shadows of Pike's Peak, near Colorado Springs, the scenery is gorgeous, although the course lies along as flat a bit of desert as exists outdoors.

Turning westward at Colorado Springs and skirting the foothills of Pike's Peak, the tourist enters the gorge of the Arkansas and the marvels of nature increase apace with each mile traversed. Canon City nestles snugly in a little valley that was hollowed out long before history began and is almost entirely surrounded by walls of porphyry, granite and limestone that tower into the cloudless sky. The Skyline drive was built by the labor of convicts to a large extent and has been carefully constructed in every detail.

At the foot of the precipice, upon which the drive runs, is the Royal Gorge boulevard. another magnificent touring road. An excursion into this part of the country would be incomplete without a trip over both these masterpieces of scenic road-building. The way from Colorado Springs to Canon City is being constructed and the few gaps that now exist will soon be filled with excellently surfaced roads which will take some of the adventure out of the tour, but which will add much to the comfort and equanimity of the traveler. The return to Denver might be the eastern route, via Elizabeth and Parker. The whole trip is slightly less than 300 miles long.

During the recent run of the Santa Fé Trail Association the participants had a glorious experience. Many of the members explored portions of the adjacent mountains where even the hardy cayuses of the prospector might have found trouble in going and all were full of enthusiasm about what they saw and found.

The pictures on this page give some idea of the party making the trip, it being a very large one, of the kinds of roads met, of the scenery which they delighted in, and many other things which would be a great source of pleasure to the Eastern man.

Assemblage of Cars on the Prairie as Used by the Santa Fé Trail Association

Automobile Apparel

Tussah Wrap

Coat of Blanket Cloth

Touring Coat

White Auto Coat

WITH the touring season rapidly approaching it is not too much to expect that the lady autoist will migrate department storeward in quest of raiment in keeping with prevailing style tendencies, and more nearly in accord with the dictates of road experience, having in mind the fact that the sun does not shine all the time. As an indication of some of the possibilities which should be of more than passing interest to the woman autoist, the reproductions here offered are claimed to be up to the minute.

On short motor drives out to the country club, or other nearby points, a coat of tussah or mohair in white or a creamy tone, with gay linings and turned-over collar and cuffs to match the lining is all that is necessary. The model shown is of biscuit-colored tussah, and completely covers the lingerie frock beneath. The lining and cuff and collar facings are of changeable blue and green taffeta, while the hat is in two shades of blue.

The looser the coat, the smarter the effect it seems. Paul Poiret has produced many of these loose, raglan-like models this season. The feature of the raglan cut is the seamless shoulder, producing a baglike fit over shoulders and arm. This coat may be donned over the daintiest frock without fear of crushing it. It is built of a lightweight, waterproof fabric, woven to withstand dust and rain. The hat, a closely fitting turban of mixed red and white straw, has a trimming of Chantecler pompons.

Dust-proof Hood

White coats are vastly becoming and look most fresh and charming against the summer background of trees and lawns. The white coat illustrated is made of English mohair and is a very dainty little model for summer wear about town. The bonnet is a Gage model of cream lace straw with ribbon trimmings in green.

No Parisienne thinks of going to the races without a pretty motor wrap tucked away in the tonneau, to don after sundown when the air grows chill. These big, wool coats are immensely chic, and that shown in the illustration is one of the very smartest of the new models. It is built of light, yet delightfully warm, wood brown blanket stuff, and the model is an entirely new one, with apron panel at the front, strapped collar, and mannish sleeve buttoned together at the wrist.

As a head covering, the hood which is shown here is designed to meet the needs of the fair autoist who has a penchant for roughing it. It is not only rainproof, but affords adequate protection when the wind blows stoutly, likewise it is invincible to dust, so that it presents all the advantages of the protective devices in use among racing drivers. To the woman of snap it offers additional advantages; a deft fold and a fanciful twist will so alter it that it will present any one of a diversity of shapes. This hood, which may be had in many waterproof fabrics, is being brought out by Sands & Maxfield, 86 North Eleventh street, Newark, N. J.

›tudies in Aviation Theory and Practice

By MARIUS C. KRARUP

he aeroplane is, at the present stage ıed mainly by staying on the ground The aviator who follows a different many chances. Tumbler aeroplanes, in geons, have not yet been produced, and ' were produced, that the power plant ıld continue to function properly in · that the aviator himself would find the loop-the-loop man of the circus. : to cope with the problem of equilibri- ır, a score of European and American furnished the solution long ago, but in analyzing the problem, is not often d constructive. Prom- inion that the preservation of equilibri- an art, and that unskilful aviators will alling precipitously to the ground. Be- s the means for accomplishing equilibri- ın at present attained, it seems neces- -cut understanding on this point. The ıishes perhaps the nearest parallel. Its ous waves is not absolute. The art of sists in maintaining it. Something more aeroplane. The bird is, perhaps, self- rings are outstretched, its nervous and ed. But shot it falls, and falls fast. An automobile is pretty well balanced on the ground, as a rule. Few object to its lack of equilibrium. Yet, it can be upset. The sense of sight in the driver and his ability to steer constitute the safeguards against loss of equilibrium with an automobile.

Approaching the subject through these parallels, it seems clear that the equilibrium to be asked of the aeroplane must be superior to that of the automobile, mostly because the aviator has not the automobile driver's chance to see and estimate in advance the foes of equilibrium which beset his path; also because in his case he can not often steer clear of these foes, as they may overtake him. The aeroplane must be self-righting or easily righted after a serious disturbance of its balance, because serious disturbances are unavoidable in bad weather. But if the aeroplane was so completely self-righting that the aviator could not steer himself to destruction, this would mean, evidently, that he could not steer at all beyond a certain very small angle of deviation from his course in any direction.

The aviator who contends for the "art" of preserving his balance is at least partly right. But can he preserve it with the machines at present at his command? Practice says no; only in fine weather. Theory says no; only in fine weather. This must be made clear. Any disturbance which throws the machine up in front or up in the rear should, according to the art, be corrected by means of the tiltplanes, but if the disturbance exceeds the range of efficient rudder action (which is about 20 degrees on either side of normal, air-cleaving position) while the momentum operates in nearly the old direction (and this is the nature of a disturbance) the value of the tilt-planes for restoring equilibrium is for the moment—a most precious moment—reduced to nil. The art is helpless, unless, as noted below, much reserve power is instantly available. If the machine is carried sideways with a gust, the tilter becomes equally useless. If the lateral equilibrium is disturbed, the effect of ailerons or warping of the planes is reduced instead of strengthened. If all three disturbances take place at once, in the degree mentioned, all three inabilities ensue. Only one factor serves equilibrium in these cases, and that is independent of the aviator, at least so far as its direction is concerned. This is the power. In the aeroplane of to-day, it acts constantly in the same relation to the main planes, and if the propeller thrust is sufficient, the machine will be shot forward, in any position given it by the wind, and the control planes, by virtue of the speed given the machine in the new direction and by the aviator's art, may be used to bring the machine gradually back to equilibrium. But, if the thrust is insufficient to cope with the position of the machine, the chance for escape vanishes.

For example, if the machine is pointed steeply upward, the propeller thrust may be insufficient to maintain the speed required for sustentation, and in that case the tilt-plane control will do no good.

(To be continued.)

Special Motors and Twin Motors

30 feet span and 5 feet fore-and-aft and area of about 300 square feet, besides ould not be counted on for support, are ight of 450 pounds, exclusive of motor, ine and aviator. The maximum weight erefore, be estimated at 1 1-2 pounds. er operating conditions, say for starts nt the most difficult periods in flight, a lift allowance of 3 pounds for each missible. By adding 50 square feet to a biplane's wing area at the rear edge, where the addition does not add materially to the resistance against propulsion, there is thus a net gain of 75 pounds lifting capacity. The designer who contemplates the employment of a motor whose weight has been cut down to 75 pounds, with more or less risk of inferior operation due to this reduction of the motor weights which have been found conducive to reliability in automobile practice, is always confronted with the other alternative of increasing the lifting capacity of his machine instead. And the means at his command to this end are so numerous and so easily applied that

the introduction of uncertainties in the power plant, even to the slightest degree, seems to be purely a relic from that past stage in aeronautics when all efforts were concentrated upon getting lift enough to leave the ground, it being at that time still unknown how easily this could be accomplished. If the designer, for reasons of equilibrium (which is a little intolerant of broad planes) does not wish to gain all the carrying capacity, which he may need for the sake of employing a thoroughly tried motor, by adding area at the rear edge of his planes, he has tilts and curvature of the planes to work with. His plans may contemplate a normal flying or starting tilt of 7 to 10 degrees. By raising this to 10 to 13 degrees, he will gain an additional lifting capacity of at least 1 pound per square foot, and while he will also need a little more power to propel his machine at the higher tilt at any contemplated speed, the net gain, assuming that he will employ the same power as first planned, will amount to at least 1-2 pound per square foot. Owing to the power consumed in the propulsion of those elements of the structure which create resistance to its propulsion without helping to lift, there is a net gain from higher tilt as well as from higher area. There is a similar net gain from higher curvature. If the designer's plans contemplate planes with 1-30 curvature, as is customary, he may add about 2 pounds gross carrying capacity per square foot and probably about 1-2 to 3-4 pound net—power requirements for a given speed considered. If it is supposed that the designer chooses to gain a total of 1 pound additional carrying capacity from all of the three sources at his command, as he may easily do in most instances without going to extremes in any construction features, he will have provided for carrying 300 pounds more of motor weight, and it remains with him and his judgment whether he will place these 300 pounds into one highly reliable motor or will prefer to divide the chance of motor troubles between two independent engines. As no automobile motor has been developed as yet which works dependably at its top rating, including top speed and maximum explosive charges, and especially none whose lubrication and cooling are quite automatic and satisfactory at maximum power development, it seems that for the present the employment of twin motors, whether intended to work simultaneously and synchronized or with one as an auxiliary to be switched into operation when the other gives out, represents that class of expedients which should be restricted to the field of experimentation, preferably for a considerable length of time, in a laboratory on *terra firma*.

As an example of a flying machine in which all the elements which produce carrying capacity have been utilized in high degree, the Demoiselle, designed by Santos Dumont, may be mentioned. With a high tilt, apparently more than 15 to 20 degrees, and a high curvature, varying in the different portions of the planes, it carries a weight of about 660 pounds with a wing surface of only about 108 square feet. The motor has 35 to 50 horsepower. Its tilter plane and steering planes are at the rear. But, by utilizing all the factors mentioned almost to the full, Santos Dumont has gotten into a new difficulty, having left very little range for the action of his control planes. If the machine dips by reason of the action of an irregular gust of wind, there are not sufficient means for compensating this tendency, the means having been exhausted by normally using the high tilts for sustentation which should be used only for control. And this accounts for the relatively poor results achieved with this inexpensive type of flying machine.

New Wright Machines at Indianapolis

VISITORS at the aviation meet on the Indianapolis Speedway, during the present week, were offered an opportunity to see five Wright biplanes navigating the atmosphere. The Wright company entered this number of machines, it is stated, and they were operated by as many members of the company's team of performing aviators who have been trained by the brothers themselves.

Interesting details of construction of these machines are shown in the accompanying photographs. The view of the tilter planes shows the addition of two small vertical surfaces, which are immobile "stabilizers" not heretofore favored by the Wrights. These surfaces will retard lateral, irregular motions under average weather conditions and will steady the effect of steering control movements, especially for beginners. At the rear of these machines a horizontal plane is added, which serves a similar steadying purpose for up-and-down movements, under average weather conditions, but it is also subject to control in the same manner as the front tilter planes are. This change is the same as was illustrated in these pages last week in a view of the new French-built Wright machines. In the view of the propeller shown herewith it will be noticed that the blade is hollow transversely, as indicated by the white curved line, but this is not a new feature. It dates back to Lilienthal and greatly increases the efficiency, especially at low speed. Another interesting feature is the use of tubes for guiding the chains and permitting the crossing of the chains for one of the propellers.

Small vertical "stabilizers" added to the tilter-plane control in new Wright fliers

How to Disregard the Rules of the Road

Presenting four dangerous situations, each of which is in violation of the rules of the road, offering an excellent opportunity to wreck the automobiles, and injure the occupants thereof, especially in mucky weather when the pavement is slippery, and particularly if the drivers ignore Newton's laws.

AUTOMOBILES are sufficiently high-priced to make a dent in the memory of the man who pays for one, provided it is wrecked on the road as the result of a deliberate violation of the rules which are laid down for safe driving. Acting on the theory that information cannot be imparted efficiently by a direct method, it is deemed expedient to show the wrong way, so that the driver who wishes to wreck his automobile will have no difficulty in selecting some one of the situations which will best serve the end sought.

Before discussing the situation in detail, it will be necessary to bring out one or two points in relation to road performance which ought to be well understood, if it is desired to have a first-class wreck. The tractive effort of an automobile depends upon the character of the tires used, their condition, and the weight or, better yet, the distribution of weight, upon the four wheels of the car as a primary consideration. Next, the road condition must be studied. Asphalt pavement, when it is dry, defeats slipping very well indeed; but in a wet condition, especially if the pavement has not been cleaned, the oil-like consistency of the débris will retard to a marked degree any attempt at bringing a speeding car to a state of rest, which condition, in the face of the fact that an automobile cannot be stopped within a certain distance anyway, if it is going at a certain speed, represents all that is necessary if a collision is courted.

Last year an attempt was made to show in a practical way that which was perfectly well understood theoretically, i. e., the distance in which a car may be brought to rest is settled by the speed at which it is going, and not by the struggle of the driver to apply the brakes with greater force, if the exigency is greater. The test was conducted on Long Island under well-defined conditions in the presence of a committee of skilled engineers, and it reresulted in average results which may be stated as follows:

Distance Required to Arrest Motion of Vehicles

Seven-passenger touring car at 40 miles per hour	67 feet
Seven-passenger touring car at 20 miles per hour	16 feet
Two horses and carriage at 25 miles per hour	64 feet
Motorcycle at 40 miles per hour	66 feet

After many attempts it was found that horses could not be stopped any quicker than automobiles, and it was also ascertained that motorcycles followed the same law, so that the practical test, which was conducted under a many-angled set of conditions, merely demonstrated that theoretical deductions will serve as a good guide, provided the road condition is properly represented, considering any given automobile, and of course the test served as a further indication of the efficacy of the law of the moving mass, hringing into prominence the limitations of brakes, which under certain conditions, become incapacitated, as when they are applied with too much force, thus causing the wheels to skid, when the braking effect is reduced to a minimum, whereas the driver may labor under the impression that he is accomplishing the maximum.

Fig. 1—How to shoot out of a lateral and hit a passing automobile even if it is on its own side of the street

In estimating what will be the performance of an automobile while it is being brought to a standstill, it is necessary to consider the situation from two points of view—(a) if the automobile is traveling in a straight line and (b) if the automobile is going around a curve. The shortest possible distance in which the motion can be arrested will be as fixed in (a); in other words, when the automobile is traveling in a straight line. The conditions (b) will depend upon the radius of the curvature, as well as upon the distribution of weight on the wheels of the automobile, and the adhesion of the tires to the roadbed. On a curve the centrifugal force of the mass must be lower than the force of adhesion of the tires on the road, if skidding is to be avoided. If the driver is particularly anxious to have his automobile skid into the gutter, all he will have to do is to speed up to the point where the centrifugal force of the mass will be greater than the adhesion of the tires to the road. If the radius of the turn is short, and the roadbed is slippery, it will not be necessary for the driver to do much speeding.

Some automobiles perform differently from others, depending upon the distribution of weight upon the four wheels as they contact with the roadbed, and upon the center of gravity of the car as a whole. It is almost unnecessary to furnish a means of predicting just what the speed will have to be to induce skidding on a curve. The average driver seems to be able to accomplish this condition without having to memorize a formula which will offer the facility of forecasting it. At all events, if v represents the speed of the car, in miles per hour and r the radius of the

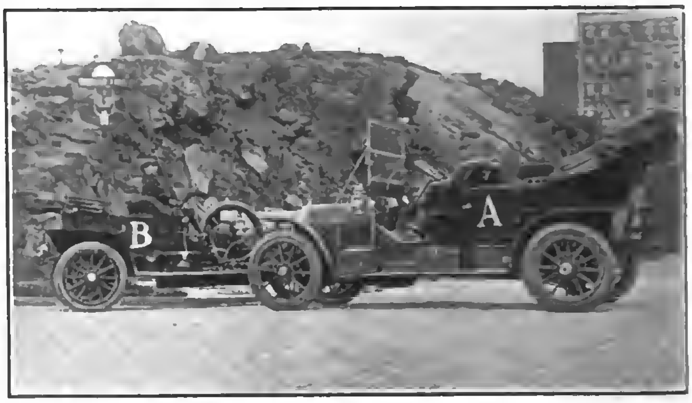

Fig. 2—How to cut in ahead of an automobile and prevent it from stopping quick enough to save trouble

curve in feet, with W for the weight of the automobile, then taking gas equal to 32.2 (the gravitational component) the following will hold:

$$v = \sqrt{\frac{2016\,g\,r}{W}} \div 1.46.$$

This is the velocity which will equal the adhesion of the tires and make skidding imminent. Of course there are a number of variables, and if the road is slippery and bad the velocity will be greatly in excess of that necessary to produce skidding.

A very interesting situation is suggested by Fig. 1. The automobile, which is emerging out of a side street, is also in direct line with a car which is going about its business on the main street. In this particular case the pavement was in good shape.

and while the driver was making a strenuous effort to stop his automobile, it is fortunate for both cars that he succeeded in doing so before the car which came down the lateral intercepted the one which is traveling on the main street. The driver of the car on the main street had a right to be there; the one which came down the lateral was in duty bound to drive cautiously.

Referring to Fig. 2, a second possibility is depicted in which the car A is shown as going up the street on the right side, which is legal driving. The car B, however, was traveling in the opposite direction, and on its right side until it came to the lateral, toward which it was turned. The car A was in its legal position, but the driver of car B was looking for trouble and turned sharply to the left, crossing the street in front of car A, putting the automobile in just such a position as would produce a collision, which was avoided in this case because it was not done on purpose.

A direct reversal of the conditions as shown in Fig. 2 are presented in Fig. 3, in which the car A is traveling up the avenue on the right side of the street, but the car B, when it came to a cross street, cut in ahead of the car A, for the purpose of turning out of the avenue into the lateral. It was obviously wrong driving, and it is just this character of road performance which is bound to lead to serious accidents in the majority of cases.

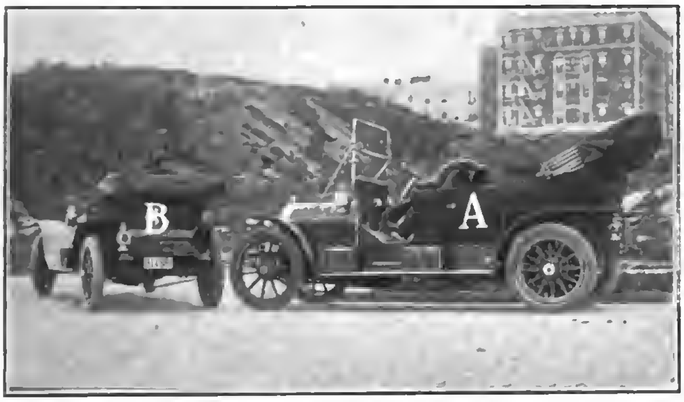

Fig. 3—Another ingenious way to get in line with a passing automobile and cause a wreck

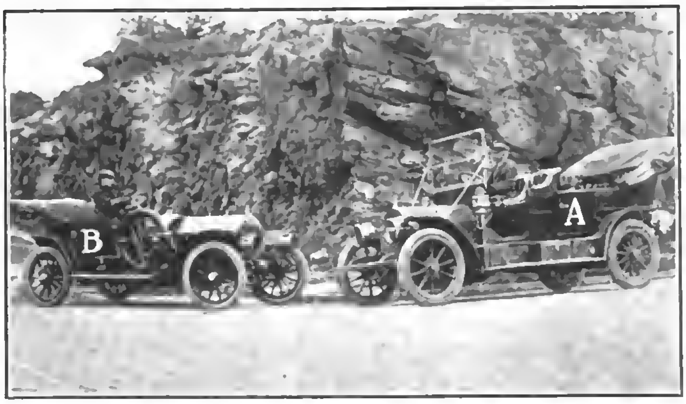

Fig. 4—One of the cleverest methods in vogue. This way almost invariably leads to a serious wreck

A very good way to wreck an automobile, with an excellent chance of bringing down a brace of them, is shown in Fig. 4. In this case the car A was traveling up the avenue on the right side, which is legal driving, and the car B shot out of the lateral, cut the in corner, which is wrong driving in any event, placing itself in line with the car A in such a way that the required distance in which to arrest motion was not afforded. Were this done in real life, instead of being premeditated, the seriousness of the situation is only too apparent. To bring wreckless driving to the absolute limit, it is necessary to do all of the wrong things that are here indicated, and, in addition, maintain the brakes in a state of bad repair, as they are in many cases in practice.

In the Process of Rejuvenating the Old Automobile

By J. B. MERCER

Working drawings of an up-to-date fore-door type of automobile body arranged for a Franklin Model H car. The new design is contrived for the convenience of an owner of an old automobile of this make if it is desired to bring the style and appearance up to the minute.

WHEN the body is out of style, the automobile is out of vogue; the only way to take advantage of the further service which the automobile may be capable of rendering is to build a new body and substitute it for the one which is at the bottom of the trouble. It is a dangerous undertaking to build a new body for a given make and model of automobile without first drawing the body to scale, making sure that it will fit on the particular automobile for which it is to be made. In a word, boots may be ordered by number with a fair measure of certainty, but automobile bodies cannot be built that way.

Referring to Fig. 1, which represents the Franklin Model H type of car as it would appear were it equipped with the fore-door style of body as here depicted. The specifications, covering the construction of this body, call for sheet aluminum, steel angle pieces, and castings to a certain extent, built up on a simple structure, such as may be hand fashioned of wood in an ordinary repair shop. Figs, 2, 3, and 4 are of the side, front, and top in elevation. Referring to Fig. 2, the framing is indicated by dotted lines. The pillar A makes the framing around the door; this is a continuous bent piece of ash extending from the top line of the seat all the way around, and terminating at the dash B. The pillar A is fitted to the curve of the seat, and the outer surface is finished so that it is in the plane of the seat panel. To prevent the joint from showing in the finished body work, this construction is rcommended, since it allows the moulding which is placed on the seat to offset sufficiently to provide a good joint. Below the seat line the pillar is fitted back on to the underbody for a distance of 3-4 of an inch, which is agreeable to the further effort, as when the moulding is placed along the edge of the panel from the dash to the seat, when it will rest in line with the vertical moulding of the seat.

The pillar forms an offset measuring from the side of the body equal to the offset of the seat at its point of contact with the same, and the dash in front is brought out to the same line. The fastenings of the pillar to the body are by screws which pass through the panel and into the body framing. The underbody (as it will be found in the Model H Franklin car) will not have to be changed, and one of the advantages of this construction lies in the case with which the new work may be added. The dash will have to be new, however, and it should be 3-4 of an inch thick, measuring up to the dimensions given in the drawing. The lock-post C is framed into the pillar at the bottom, and to the side rail at the top. The surfaces of the sides, and the door, should be covered with No. 16 gauge aluminum, fastened under the moulding at the top, to the curvature of the dash, and to the outer edge of the pillar. It should be turned in around the doorway, and at the joints of the front of the side of the seat.

The upright curve moulding, which gives effect at the pillar, should be riveted to the panel. On the right side, the framing and the moulding should be the same as on the left side, excepting that there is to be no cut in the door on the left side.

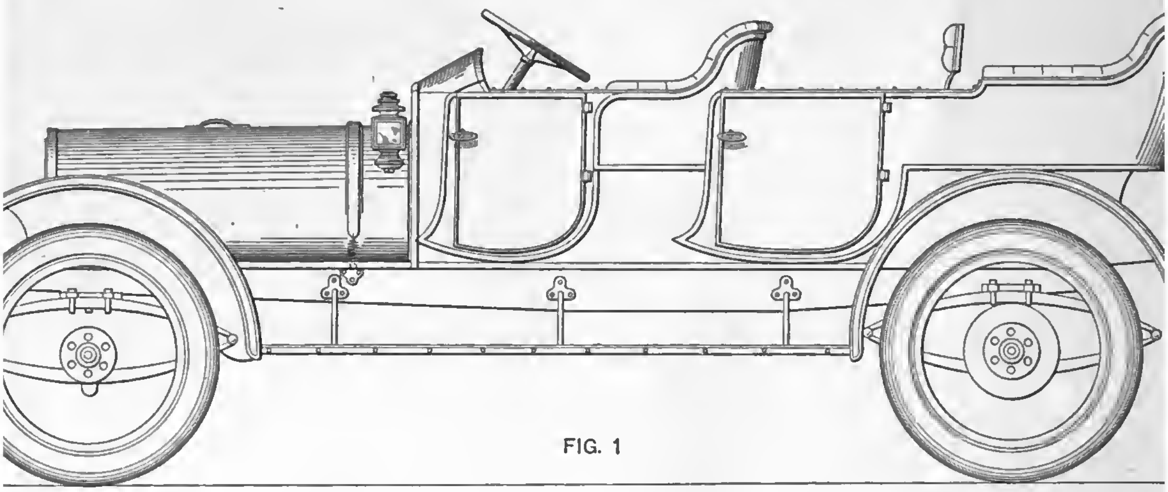

FIG. 1

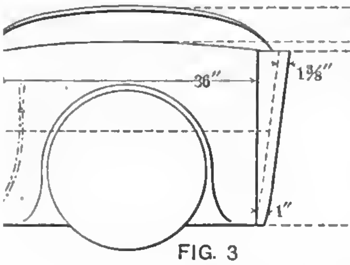

FIG. 3

It would not be so bad were the body kept in the oom until the chassis is overhauled.

Accessibility is a Much Sought-for Je

Is it not rather strange that makers of automobile tenaciously to the conventional designs which do n accessibility of the parts which are the most likely to order? Why should a carbureter, for illustration, be tween a red-hot exhaust manifold and a chassis frame, if it is of the type that is provided with four or five adjustments, and is so contrived that the new owner to go through a series of maneuvers for perhaps two days after the automobile is delivered into his keeping. this very inaccessibility of the carbureter is at the bott reason why the automobile is delivered to the purchas a state of incompleteness that he will have to tune i wants to go anywhere. Why should not the designer c tuning up if he is so short of ingenuity that he is co place the carbureter (of the type which must be adju place where it cannot be got at?

Forced Lubrication—Trend in English P

By R. K. MORCOM

(Second Installment)

Dealing with the problems of lubrication with especial reference to force feed methods, showing how plain bearings are designed, and the results obtained. Very simple oil grooves are shown, and it is claimed that all that is necessary is a circumferential groove which will allow the oil to enter, so that a supply of oil is assured at the point of minimum film pressure. This is the second installment of the article as it was abstracted from a paper by R. K. Morcom, and read before the Inst. of Auto. Eng. (British), May 11, 1910.

THE chief points favoring forced lubrication brought out by the trials were its rapid adaptability to various conditions, its very positive maintenance of the all-important oil film, and the simplicity of the provisions necessary to ensure perfect lubrication. With splash and gravity systems elaborate oil grooves, troughs and oil ways are required, and often they are cut without due regard to theoretical considerations. With forced lubrication very simple oil grooves are satisfactory. All that is necessary is to provide a circumferential groove whereby a supply of oil is ensured it whatever point the minimum film pressure exists; the oil at this point will be 'orced right along the bearing, ensuring a perfect supply. Where nore circulation is required, one or more horizontal grooves may e cut in the bearing at suitable points, forming practically an il pad, and also by increasing the circulation, having an importnt cooling effect on the bearing. Circumferential oil grooves hould not form a continuous band, but should be staggered, thus reventing the formation of a ridge on the journal due to lapping action.

Figs. 6 to 8 give suitable designs of oil grooves for forced lubrication.

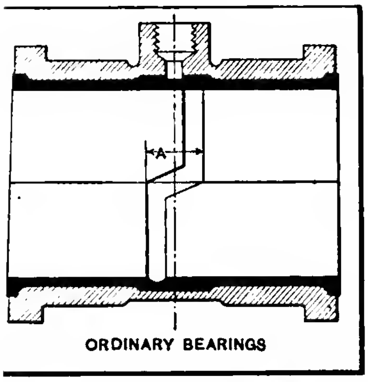

Fig. 6—Ordinary bearing with white tal lining, designed for forced lubrition

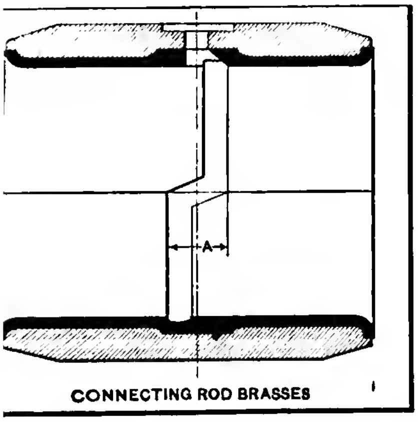
From various experiments it has been shown that bearings with forced lubrication will carry greater loads per square inch than others (this is largely due to the cooling effect of the copious supply and the certainty of the distribution), and it is interesting to consider the forces acting upon bearings in a motor car engine and those existing in a stationary engine of larger size. The load curves in Figs. 9 11 are fairly typical. The short period of reversal is noticeable the petrol engine diagrams. The loads and rubbing speeds in neither case are very high, and are exceeded in many so-called slow-speed engines, and considerably exceeded in steam turbines.



g. 7—Connecting rod bearing with e metal lining, designed for forced lu- ition

The extent to which forced lubrication is applied varies with different makers. Some apply it to main bearings only, and others to main bearings and crankpins; others carry it to the gudgeon pin, and in some cases it is also carried outside to detail sion.

There seems little rea pump is included in the d the pressure at any rate gine.

To consider the appli parts of the engine in de ings in a forced-lubricati closed in, and provided exists can be kept very cl or trough systems dirt n collect in the open oil quent trouble. The oili forced lubrication is ver tive, whereas with splas care is often required to ensure a correct s these and other bearings in which reversals ta film is maintained by forced lubrication.

For oiling the gudgeon pins which are heavi comparatively small reciprocating motion (see to be said in favor of forced feed. There is to "cake" and often carbonize on the crank ca ton head, and the drip system usually arrang lubrication may be a source of trouble, carbo bon dropping into the oil ways, and causing wear or clogging of the oil hole. Also, the oil is heated by the piston, and may be very hot and thin when it reaches its point of application.

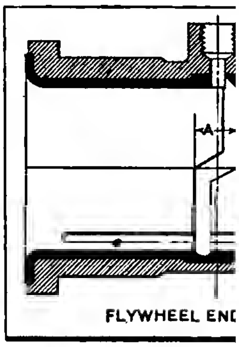


Fig. 8—Flywheel end length, with white me ranged for forced lubric

With forced lubrication supplied through a hollow rod or external pipe, a supply of clean, pure oil is ensured. One of the great merits of forced lubrication is that it is easy to prevent excessive oil being carried up while with splash lubrication the difficulty of quate supply to the gudgeon pins often leads cation of the pistons, and subsequent trout valves and ignition. A sheet of metal with placed just to clear the big ends has been fo practice.

The forced system requires means for preventing the efflux of oil from the main bearings. This is easily done by properly designed end plates, and baffles or thrower rings on the shaft.

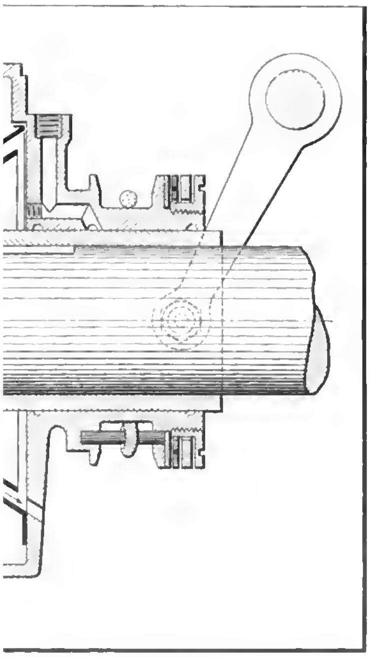
mechanism t an ordinary n locking the ame time has e pressure of in accordance 1 case and—by ordinary brake f bringing a needed, much ie without it, a French captain of artillery, and nobiles and railway cars. Briefly, e that of a centrifugal brake brought 1 in turn actuating a normal brake red type. The leverages regulating ioes may be increased, or the diamty be increased, without fear of ext sudden application of the mechanp the wheels from rotating, whether erwise, since under all circumstances ie live wheel axle which determines sure. In the accompanying illustraed by the driver to push the clutch he flanged sleeve, which is keyed to the intermediate ring. By this action pressed against the adjacent surcssure proportional to the driver's time the weights, which are provided are free to move radially between 1 to the flanged sleeve, are thrown lrical surface of the friction ring. is engaged to rotate with the wheel ugal pressure is sufficient to make it rotate is transmitted by a cable everage sufficient to produce a very strong effect if the centrifugal action of the weights is pronounced. It seems from the description that the driver's braking effort, when applied to the lever, is simultaneously applied to an ordinary brake, which in automobiles may be the external wheel brake or may operate internally in the drum, parallel with the centrifugally actuated brake, by dividing the drum surface into belts, one of which receives pressure from the ordinary brake and the other from the centrifugal brake. In whatever manner the ordinary brake action is arranged, its surfaces and leverages are so adjusted that this brake alone is incapable of locking the wheels at high speed. It is stated that the coefficient of friction between a brake shoe and a drum is much increased when the rapidity of motion of the revolving parts is reduced, and that this accounts for the very slight initial effect of ordinary brake action (the momentum alone, it is said, being insufficient to explain the observed results). In accordance herewith the combined action of the centrifugal brake and the ordinary brake, both operated at the same time, is shown graphically in the accompanying diagram, which also shows the curve of the simple customary brake action for comparison. A lengthy description of the Hallot system is given in *La Vie Automobile* for March 12 and a mathematical discussion of the interdependent forces set in motion by this compound braking system is presented in *La Technique Automobile et Aérienne* for April 15.



mitting braking effort to the more akes. Hallot brake system

Celluloid which does not burn may find new employments in automobiles and aeroplanes and is already displacing the old inflammable celluloid for cinematograph films. It is no longer a product of gun cotton, camphor and alcohol. The cellulose base is in the form of special acetates (acetic acid taking the place of nitric acid in the whole process), held in solution in tetrachlorides of acetylene or in suitable mixtures of denatured alcohol, acetic ether and amylic acetate. The material, called cellite, was developed by Dr. Eichengrün, a German savant, and is produced industrially by Bayer, Liesegang & Badische Anilin Company, of Darmstadt, Germany. Instead of the expensive Japanese camphor, the inventor has succeeded in making a synthetic camphor whose composition may be varied so as to produce celluloids, or cellites, more or less hard, and even as elastic as rubber. For other purposes than photographic films, in which perfect transparency is required, the new material will be cheaper than the old. The author intimates that the Eastman Company and the American Celluloid Company, the world's principal producers of films, may have been licensed to use the new process. In Franch, Dr. Clément Botrelle has developed another uninflammable celluloid in which there is substituted for the ethyl ether usually employed in the manufacture an ether of silicious base (Botrelle uses a hex-ethylic disilicate) which, when it evaporates, does not only bind the nitrated cellulose together, but also coats it with silica.—*Le Génie Civil,* May 14.

Elaborate investigations of offset of crankshafts by v. Doblhoff were referred to in these columns in the issue of May 26. In his continued report on this subject the author enters upon consideration of the reactions upon the motor and the motor suspension of the changed torque elements of the crankshaft, these reactions being among the causes of vibration in automobiles and therefore important. It is noted that with offset crankshaft the piston pressure enters as a factor in constructing the parallelograms of the tangential forces acting and reacting at the crankpin, while in a straight motor the piston pressures are the same on both sides of the shaft and compensate themselves. The conditions differ somewhat, as between single, double and four-cylinder motors, and according to whether the cylinders are cast singly or in batteries, some of the stresses being balanced and annulled when the cylinders are cast *en bloc.* To arrive at his formulas the author is compelled to assume certain dimensions of the motor parts and he averages these from a number of actual four-cylinder designs. On this basis he develops graphically complete diagrams and curves showing the modifications in nearly all of the forces set going in five types of motors; namely, one normal motor, one with crankshaft offset one-fourth of the crankthrow, one with one-half offset, one with three-fourth offset and one with offset equal to the whole crankthrow. The friction of pistons (apart from the friction due to the expansive pressure of piston rings) is shown to decrease rapidly with small offset and then again to increase very rapidly at high offset, due of course to the high values on the compression and exhaust strokes. The balancing of the four-cylinder motor is shown not to be affected by the offset. A table is presented giving the numerical values for the various forces involved, and the total result is in favor of one-half offset, as previously mentioned. As incidental advantages, perhaps superior to the gains in mechanical utilization of power, the author mentions that the camshaft may be placed nearer to the crankshaft, if valves are all placed on one side, opposite to the offset, where they also ought to be for thermic reasons. By this disposition the camshaft gears can be made smaller, and no intermediate gears will be required, while noise will be reduced. To get these advantages in full measure it will, however, be necessary to cut a slit for the connecting-rod in the lower portion of the cylinder wall, and the author shows how this should preferably be done. The offset motor should be designed to turn "right" instead of "left," as is customary. Then the cylinders can be placed a little to the right under the bonnet; the camshaft, the valves and all auxiliary organs, as pump and magneto, can be placed to the left, where they are accessible, and there will be ample room left for the steering pillar and gear to enter the bonnet to the right, and the exhaust can be taken rearward on the left in the usual way without interfering with pedals and steering gear.—*Der Motorwagen,* May 10 and 20.

The square motor seems definitely abandoned. The ratio of stroke divided by bore oscillates from 1.2 to 1.4 for single cylinders, with an upward tendency. The long-stroke motors have shown what they can do in the recent voiturette races. A 100 x 120 gives about 12 horsepower: a 100 x 140 gives already 14 horsepower; a 100 x 180 exceeds 18 horsepower; and finally a 100 x 250 gives more than 30 horsepower with a fuel consumption lower than that of the 100 x 120. While the 100 x 250 will not become general, it is an assured fact that the 100 x 120 and even the 100 x 130 will presently prevail over the square type. In four-cylinder and six-cylinder motors the increase in the ratio of stroke to bore is still more notable. Motors of 75 x 125 and even 75 x 150 are current to-day, also 65 x 105 and 65 x 130. In brief, theory says long motors with high piston speed, and practice does not contradict the theory.—*La Vie Automobile,* May 14.

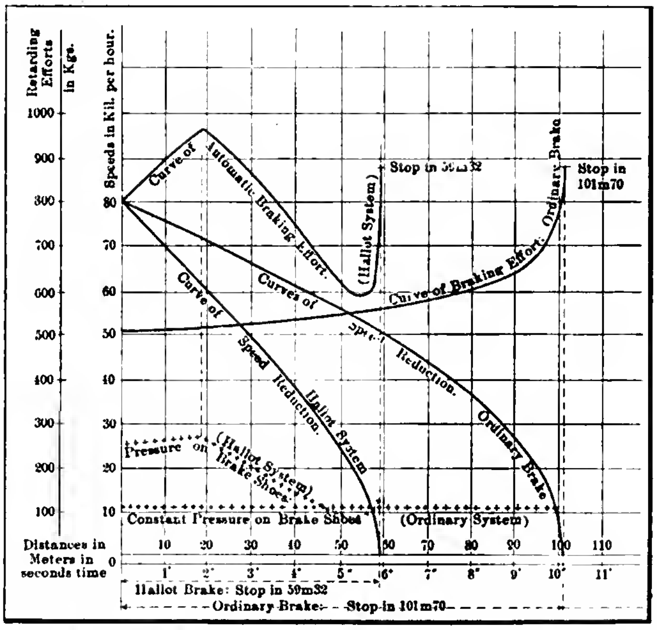
In a treatise on ball and roller bearings in *Technique Moderne* for April the author calls attention to the frequency with which the maximum stresses figured on by designers and according to which the dimensions of the bearing members are selected, are calculated from normal running conditions of the vehicle, while the balls or rollers and the races are in reality subjected to much heavier strains when the brakes are applied. In calculating formulas for maximum loads he sets aside the tensile strength and the elongation of the steel used in the bearing members as unimportant in comparison with the elastic limit and the modulus of elasticity and arrives at the result that, for a given diameter of the bearing and also given transverse dimensions, a roller bearing in which the rollers are rounded and run in races of similiarly rounded cross-section, and in which a suitable cage is provided, will not only support loads nearly four times as large as those a ball or ordinary roller bearing will endure, but may also be more easily mounted and dismounted.

Those interested in synthetic rubber and its economical production will find in *Engineering* (London) for May 13 an exposition of the work which has been done in this direction, with a list of the workers who have been or are engaged in it, the chemical difficulties met when organic substances are subjected to violent reactions, and a statement of the latest results.

When a glass bell in which a fly is captive is placed on a most minutely accurate pair of scientific scales, it weighs exactly the same, whether the fly sits on the wall or flies around the air in the bell. From an article by F. Bendemann in *Zeitschrift des Vereines Deutscher Ingenieure.*

"To build an aerial propeller without a more or less hollow pressure surface would nowadays scarcely occur to any designer," says C. Eberhardt in the preface to his important work, "Theory and Calculation of Air Screws, with Examples and Experimental Results from Practice." The author, whose untimely accident was recently announced, had for a number of years been the leading designing engineer in connection with the German military dirigible balloons, and as such had opportunity to verify in practice those design formulas for propellers which are placed at the disposal of the reader in the work referred to. If he had not found a very close correspondence between theory and practice he would not have dared, he says, to recommend his results for practical application by others. Throughout the book the mathematical deductions are presented as simply as possible, while the reasoning is submitted step by step to the reader's judgment. Good judgment is more important to the working engineer than mathematics, the author admits, but can only be developed on the basis of rich experience in the special field in which it must be exercised. Lilienthal's experimental research on the subject he has usually found correct and applicable, as far as it goes. And in accordance with this early investigator, the arching of the propeller surface should decrease in degree as the linear velocity increases. In the propeller of the Wright machines it is found, however, that the arching or curvature is about 1-26 near the hub and increases to about 1-20 at the ends, which is not considered correct, but probably is dictated by considerations of strength and the comparatively small importance of the propeller's efficiency in the portions whose velocity is smallest.—Published by M. Krayn, Berlin, W.; price 6 mark.

A certain steam motor builder in one of the northern counties still uses "flat" drills, even for drilling holes that should bear some resemblance to a circle.—*Commercial Motor,* June 2.



Comparative diagram of stop action with the Hallot system and with ordinary brakes

ɔns That Arise—General in Scope

Outlining the importance of using pure ingredients in the manufacture of storage battery solutions, and affording methods of testing in order to locate iron, copper, mercury, nitrates, and chlorine in electrolyte. The effect of temperature is discussed and acid strength for each temperature change is taken up.

Iron may carelessness; the aver- of determining if the cells are "dead," using a screwdriver as a means of short-circuiting the plates or elements of the battery; the screwdriver will be partially dissolved in the electrolyte. Iron is also present in sulphuric acid, which is made from iron pyrites; this character of sulphuric acid should not be used in the manufacture of sulphuric acid electrolyte. Mercury may come from the thermometer bulb; if one is broken during the taking of temperature, this trouble will be imminent. Hydrometers, as used in battery work, should be shot-ballasted; mercurial poisoning will then be avoided. Copper comes from the close proximity of the copper leads and brass terminals used in connecting up the batteries.

[103]—Which of the impurities is the most damaging?

Nitrates, perhaps; chlorine is very detrimental; mercury is much to be avoided; copper is not so bad; iron has a very bad effect upon the strength of the supporting grids.

[104]—How much of these ingredients may be tolerated in batteries?

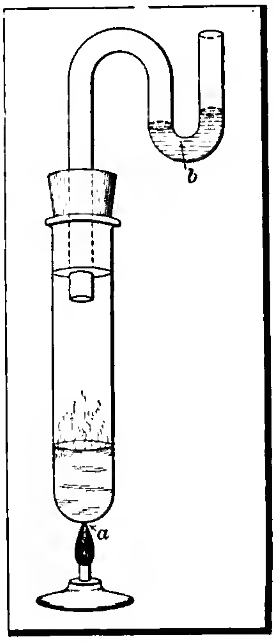
The merest trace will have its effect in time; just enough to strongly indicate the presence of a nitrate, chlorine, or iron, will be sufficient to demand that the battery be subjected to a purifying process.

[105]—By what method can a battery be rid of such undesirable elements?

(a) Charge the battery to drive out all the sulphion; (b) substitute pure electrolyte for the contaminated solution; (c) repeat this performance as many times as may be necessary, discharging the battery each time in its fresh bath of electrolyte before substituting the new and pure electrolyte. During each new charge some of the impurity will be driven off.

[106]—How may a test for chlorine be made if it is suspected to be present in a storage battery and it is desired to purge the battery of this dreaded impurity?

To a small quantity of the electrolyte of the battery in a test tube, add a few drops of nitrate of silver in solution: a curdy white precipitate, if it forms, will denote the presence of the chlorine. The white formation is soluble in ammonia water, and is precipitated out by nitric acid. This precipitate is chloride of silver, which will melt to a horny mass, and when exposed to light, turns violet.



Nitrate test tube which is used when it is desired to locate a mere trace of nitrate in electrolyte

[107]—By what method may iron be detected in a battery?

The per salts of iron are foxy red. In solution with yellow prussiate of potassium the yield is dark prussiate of blue, and this fact leads to prompt detection. Proto salts of iron, on the other hand, are green, and their solutions precipitate with red prussiate of potassium; use solutions of potassium in making the respective tests.

[108]—In what way may mercury be detected if it is present in a battery?

Mercurious salts deliver a black precipitate if limewater is added. The precipitate will be olive green if iodide of potassium is used instead of lime water. For mercuric salts, on the other hand, the precipitate will be yellow if lime water is added, and it will be scarlet if iodide of potassium is added.

[109]—What is the nature of the test which is utilized to detect copper in a battery?

To the electrolyte add liquor potassæ. A blue precipitate will fall down; it will prove out as copper if it turns black when boiled.

Report on Cast Iron Test Bars

(Second and Last Installment)

IN order that we may be able to construct a formula to be used in the design of a beam made of material whose crushing and tensile strength are not equal, we must know the ratio be-veen them. It may be reduced as follows (referring to Fig. 1, ıne 9 issue, page 1053):

Let M = bending moment $= \frac{Pl}{4}$ for load at center of span.

P = load at center.
l = length between supports.
S_c = compressive strength.
S_t = tensile strength.
b = breadth of beam.
d = depth of beam.
a = distance to extreme fiber on compression side.
f = distance to extreme fiber on tension side.
K = ratio compressive strength to tensile strength.

All dimensions are in inches.

We have the moment of resistance on the compression side

$$\int_o^a b\sigma y\,dy = \int_o^a bS_c\frac{y^2}{a}dy = \frac{ba^2}{3}S_c$$

d in like manner we find the moment of resistance on the ısion side to be $\frac{bf^2}{3}S_t$. Since these two resistances are on ›osite sides of the neutral axis they must be equal, or

$$\frac{ba^2}{3}S_c = \frac{bf^2}{3}S_t \text{ or } \frac{a^2}{f^2} = \frac{S_t}{S_c} = \frac{1}{K}$$

$$\therefore f = a\sqrt{K}$$

ince the sum of these two resistances must be equal to the ding moment we have

$$M = \frac{ba^2}{3}S_c + \frac{bf^2}{3}S_t$$

stituting KS_t or S_c

$$M = \frac{bS_t}{3}(Ka^2+f^2) = \frac{Pl}{4}$$

$$Pl = \frac{4}{3}bS_t(Ka^2+f^2) = \frac{8}{3}bS_ta^2K$$

$$d = a+f = a(1+\sqrt{K})$$

$$\therefore a^2 = \frac{d^2}{(1+\sqrt{K})^2}$$

tituting again

$$Pl = \frac{8}{3}bd^2\frac{K}{(1+\sqrt{K})^2}S_t$$

$$S_t = \frac{3}{8}\frac{(1+\sqrt{K})^2}{8K}\frac{Pl}{bd^2}$$

e substitute 1.747 for K we get $S_t = \frac{Pl}{1.155\,bd^2}$ or Clark's ıla.

cing the average compressive strength of cast iron as ›o lb. per sq. in., and the average tensile strength as 28,000, = 4, we have

$$S_t = \frac{Pl}{1.185\,bd^2}$$

Applying this formula as Mr. Nagle does Cla we have

$$\frac{2372 \times 1.185 \times 2 \times 1 \times 1}{2.4} = 23$$

As will be seen, this formula gives results with those obtained from the test.

A. A. CARY. It is unfortunate that the value study of metals and alloys, by use of the pyro scope, is not more widely appreciated. I fe that by such means all variations such as note paper can be most satisfactorily accounted for. the fact is now generally recognized that m chemical composition may possess widely dif properties which are quickly recognized by m ination.

Chemical analyses, as given in Table 1 of t doubtedly of considerable value in the investiga but without a physical examination our knowle of the metal to withstand stresses and strair tain. Not only will investigations of this k cause of the variations noted in Mr. Nagle's pa give us the information needed to produce a uniformity.

PROF. T. M. PHETTEPLACE. It would be int whether a thorough sand-blasting would hav different results seemed to be obtained by clea of the material.

THE AUTHOR. Since the paper was written portunity to examine some instructive record (of three each) of round test bars. The bars in diameter, rough, on 12-inch supports, the bre corrected for actual diameters. The deflectio rected.

BREAKING LOADS IN POUNDS, DEFLECTIO TO 0.15 IN.

1........	3,276	3,185	3,044	4,400	4,005	2,913	3,276	3,3
2........	3,367	3,276	3,162	3,100	3,913	3,003	3,185	3,2
3........	3,276	3,534	3,255	3,500	3,640	3,115	3,026	2,9

The three bars in each set were cast in thre No. 1, or the upper line, being cast from the ladle, No. 2 from the middle, and No. 3 from will be observed that in eight of these eleven lected from the two nearest in agreement, came of the pour, and that all of the extreme varia in either the first or last pour. If we have or would differ as much as 22 per cent, while if out of three nearest in agreement, those two more than 2 per cent. or 3 per cent.

I am very glad that Mr. Peek has taken up solution of fitting a formula to the facts. Wh stration or Clark's is the correct, or the bette attempt to say, but it is a pleasure to find that agree so well with the facts. I trust that this p ish the old form of formula from the text bo

Professor Gregory has made an oversight in t my bars. Being twice as wide as his, the deflect very great variations: as 4 by 0.09 = 0.36 to by 0.09 = 0.72 to 0.45.

I have had no experience with bars 1 inch by 1 but I think that 0.15 inch deflection would be in machinery castings.

The Relation of Weight to Roadability

Editor THE AUTOMOBILE:

[2,289]—Generally speaking, is a light or a heavy weight car preferable for use on sandy roads? The various advocates fail to agree on this point. Surely there must be some principle involved. Perhaps some reader of THE AUTOMOBILE will be able to evolve a reasonable answer. FRANCIS E. LESTER.

Messilia Park, N. H.

There must be sufficient traction to transfer the power of the motor, as it is demanded in the process of driving the automobile, to serve the end. This is a matter which is controlled by the weight on the driving wheels. Every automobile, be it light or heavy, seems to satisfy this demand. If the going is bad, there must be power enough to drive the automobile when the wheels sink into the roadbed. If the wheels are of large diameter, the situation seems to be improved. Under the circumstances it would appear as if three points must be considered, i e.:

(a) The power must be adequate for the purpose.

(b) The traction must be enough to prevent the road wheels from slipping.

(c) The diameter of the road wheels must be large enough to keep the grade within that which an automobile can negotiate; they travel up grade all the time that they are in a depression.

A Question in Relation to Front Wheels

Editor THE AUTOMOBILE:

[2,290]—Will you state why makers of automobiles set the front wheels out of the vertical plane? J. B. WILSON.

Toronto, Canada.

It is desired that the wheels ride on "plumb" spokes; the road is given a camber; the wheels are set to the same angle from the horizontal, in order that they will ride on plumb spokes.

Why Are Cylinders Beveled at the Bottom?

Editor THE AUTOMOBILE:

[2,291]—I went into a garage the other day and the repairmen were working on the cylinders of a motor, and I noticed that there was a bevel at the bottom of the cylinders. What is it for?

Buffalo, N. Y. CURIOUS.

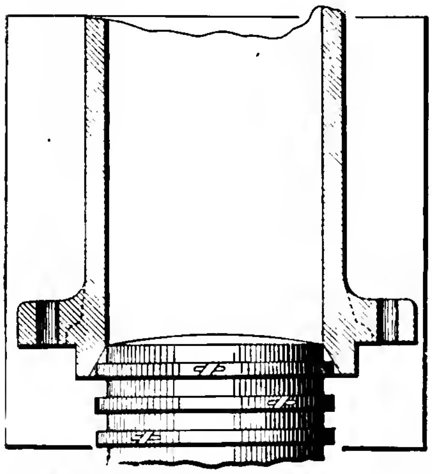


Fig. 1—Showing bevel at the bottom of the bore of the cylinder which is there to help enter the piston

The use of the bevel is shown in Fig. 1. When the piston is being put back into the cylinder the piston rings will be in the expanded position, and without the bevel it would be almost impossible to insert the piston without at least damaging the rings. With a suitable bevel and the use of two pieces of flat steel, the pistons may be put back into the cylinders, and the rings will close in without trouble.

Series Connection for Ignition Batteries

Editor THE AUTOMOBILE:

[2,292]—What is the right method of connecting ignition batteries, using, say, five dry cells? NEW OWNER.

Erie, Pa.

See Fig. 2. The inter-connections are from zinc to carbon in each case; one lead from the interrupter goes to the zinc at one end and the other lead to the carbon.

Gasoline Will Cause Carbon Accumulations

Editor THE AUTOMOBILE:

[2,293]—I do not see how the use of a limited amount of good lubricating oil will result in an accumulation of carbon in the combustion chamber of a motor, but the carbon does accumulate, and I am at a loss to account for it. SUBSCRIBER.

Nashville, Tenn.

Referring to Fig. 3, A represents the motor cylinder, B is the piston and C is the mixture which is too rich in gasoline, and carbon is precipitated out. The figure to the left, in the same view, is of a retort in which D is the carbonaceous material which is placed in the hermetically sealed chamber for the purpose of distilling off the more volatile matter, and the residuum is carbon. The door C of the chamber must be tight enough to exclude air. E represents a fire built on a grate in a fire box under the chamber D. Fuel is placed on the grate through the door B: draft is through A, and the grate up the chimney G; ashes are shown at F. The combustion chamber of a motor is to all intents and purposes a chamber such as that shown at D, and if carbonaceous material is placed in the combustion chamber C of the motor cylinder, without enough oxygen to burn the carbon, the residuum will be the very carbon complained of, nor does it matter that the carbonaceous material is in the hydrocarbon form known as automobile gasoline. The way to avoid this carbon formation is not to use too much gasoline.

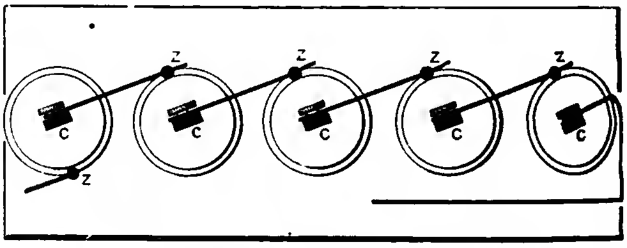

Fig. 2—Showing series connections of dry cells of battery as used in ignition work

Depends Upon Pressure or Gravity Feed

Editor THE AUTOMOBILE:

[2,294]—Will you please answer the following questions through the columns of your paper:

1. How are gasoline tanks on automobiles located with reference to the floor of the car? Are the bottoms of tanks above, below or on the level with floor in general?
2. What is the usual capacity of gasoline tanks now in use?
3. What are the shapes in use?
4. Is there such a thing as standard sizes, or does each company make its own particular shapes and sizes?

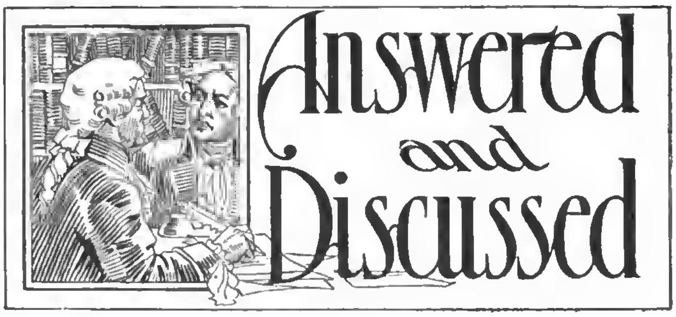
Bridgeport, Conn. JAMES S. HALL.

1. In gravity feed work the gasoline tank must be located at least one foot above the float bowl of the carbureter, which condition is independent of every other consideration. In pressure feed work the gasoline tank is located below the deck of the body, and generally below the top of the chassis frame.

2. The capacity of the gasoline tank for a 50-horsepower touring car is about 20 gallons. For a 30-horsepower touring car it is about 16 gallons, and for a 20-horsepower car it is about 10 gallons. A five-gallon tank will feed a "one lunger" for 100 miles.

3. Round or oval tanks are preferred; walls without curves bulge out unless they are braced by means of surge plates, of which two are used in most tanks.

4. Each company uses a gasoline tank which will fit into the space available in view of the design, and the placing of other essentials.



Transformer for Recharging Storage Batteries

Editor THE AUTOMOBILE:

[2,295]—Will you kindly describe in your "Letters Interesting, Answered and Discussed" how to construct cheaply an efficient transformer for recharging storage batteries, say from alternating current (110 volts), as supplied for lighting purposes, and the ordinary storage battery, 6 volts, 60 amperes? G. H. J.

San Mateo, Cal.

Storage batteries cannot be charged by means of a transformer. The transformer would still deliver an alternating current, and since an alternating current delivers its impulses in alternate directions the battery would be discharged as much as it would be charged per cycle of the alternating current. A mercury rectifier will do this work. They are not easy to make in an experimental way, but one can be had at a reasonable price from some one of the big electrical companies who manufacture them.

Look Out for Secondary Moments in Speeding

Editor THE AUTOMOBILE:

[2,296]—As the rating of the horsepower of an automobile is based on piston travel of 1,000 ft. per minute, hence a 3 3-4 x 4 stroke, 4-cylinder car, must make 1,500 revolutions per minute. Is this a practical velocity of speed, and if not, what is considered a practical speed that will not abnormally injure the car? Are some cars built for higher speed than others, considering safety, and if so, what are the features to enable one car to run at a higher speed than another without injury? When is a car in such a condition that it can be called "worn out"? What condition can a car be in and not be said to be worn out? H. P. NICHOLS.

Nichols, Conn.

The speed named for a motor with a 4-inch stroke to obtain a piston travel of 1,000 feet per minute should not be unsafe. It is not possible to state offhand the safe speed of any motor; it depends upon the magnitude of the secondary moments beyond a certain speed, and the secondary moments in turn depend upon the weight of the reciprocating mass, and other unbalanced components. The design of the motor must be investigated, and calculations must be made from exact data, which can only be obtained as the result of a careful investigation.

An automobile is worn out when it is reduced to a state where it gets on the nerves of the owner.

How to Know When Tire Is Deflated

Editor THE AUTOMOBILE:

[2,297]—Do you know of any device which will let the chauffeur know when a tire becomes deflated, while running? If so, please give me the address of the manufacturer. R. M. HARBIN.

Rome, Ga.

A real, live chauffeur, were he paying attention to the automobile and the road ahead, would hear the differential gear when it is thrown into action, if one of the tires of the rear wheels flattens. When the two rear wheels are of the same diameter there is no relative motion of the sun and the planets of the differential gear. A dead chauffeur would not even know if a front tire should go down; a live one would see it. In the meantime, there are devices to be had at supply stores.

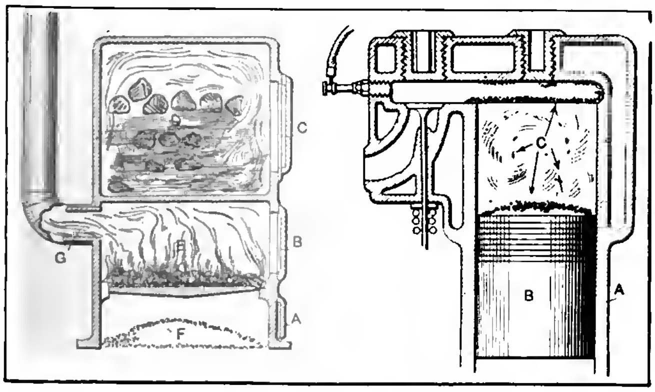


Fig. 3—Coke oven, showing its relation to the combustion chamber of a cylinder of a motor

Proper Gear Ratio for Motor Delivery Wagon

Editor THE AUTOMOBILE:

[2,298]—Kindly answer the following question through the columns of your paper. What should be the proper gear ratio for a motor delivery wagon of the following specifications: 1500 lbs. maximum load capacity; weight 2200 lbs.; motor 2-cylinder opposed, 4-cycle, water-cooled; 5-inch bore, 4-inch stroke; wheels 36 inches in diameter? F. L. S.

Toledo, Ohio.

In this connection it may be well to prefix the statement that delivery wagons are generally geared so that they travel too fast. The law of depreciation cannot be stated in such absolute figures that they may not be controverted by the wise, but in a general way the following will hold:

Speed in Miles per Hour	Life of the Car
5	100 per cent
10	25 per cent
20	6.25 per cent

The figures given are relative, so that the initial speed should be set in accordance with the characteristics of the automobile. Five miles per hour would probably be a good speed for a 4-ton car, so that in your case you might increase from five to eight miles per hour without seriously affecting the initial life. Under the circumstances, considering the difference between loaded and free speed of the motor, it would appear to be good practice to employ a gear ratio of 10:1. You probably will not care to advocate low speed, and it will be up to you to decide as to how much faster you wish to have the automobile go, thus leaving it to the purchaser to decide as to the magnitude of the repair bill.

Read "The Automobile"—See June 9 Issue

Editor THE AUTOMOBILE:

[2,299]—I have a car which is equipped with the Bosch High Tension Magneto for ignition only, and wish to equip it with an extra system so I will be able to start on the spark. Can this be done by using six dry cells, a single vibrator coil, and the timer and distributor of the magneto? Is it considered bad for an engine to be started on the spark? SUBSCRIBER.

DeLancey, N. Y.

Spark Should Not Be Retarded

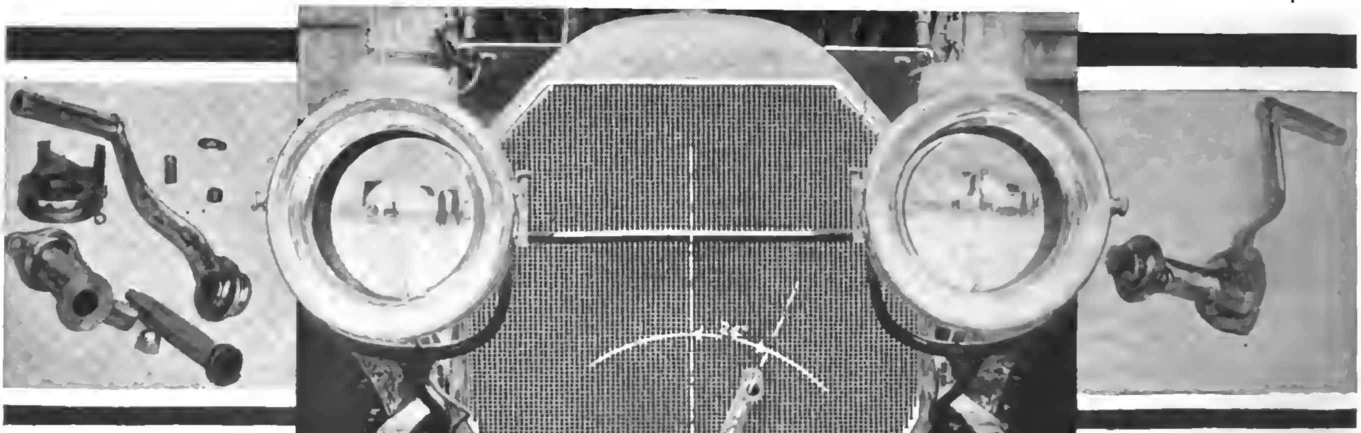
Editor THE AUTOMOBILE:

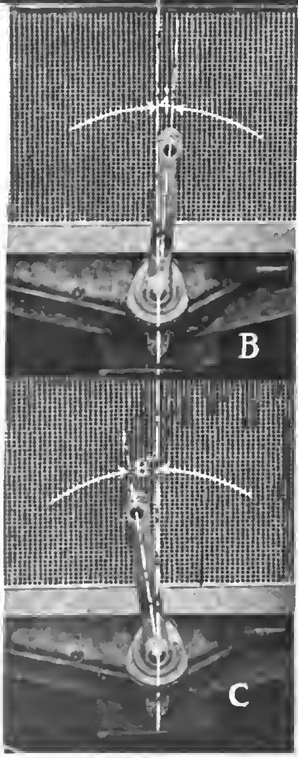
[2,300]—Will you kindly inform me if it is correct driving to have the spark advanced when going down a hill, shutting off the throttle entirely, and throwing out the clutch if the hill is not long enough to warrant cutting off the ignition entirely and coasting down? I have always understood that to leave the spark advanced is an excellent chance to cool off the motor while rolling down hill, and is also economical. Will you give me your valued opinion to settle an argument with one who always retards the spark when going down hill? E. L. G.

Flushing, N. Y.

The spark should not be retarded too much at any time whether going up or down hill or on a level. If the spark is cut off when a car is coasting, a muffler shot will be generated when the spark is thrown in again and the accumulation of mixture in the muffler and exhaust piping may be sufficient to disrupt the muffler. Running on a retarded spark causes undue heating of the automobile engine, and the exhaust valve is likely to be warped as well.

The Problems of Standardization Are Prominent





ACCESSORY makers serve all the automobile manufacturers, and in order to have the accessories on a standard basis it is necessary that each automobile maker conform to a given standard, so that the accessories will fit when they are delivered for use on the respective automobiles. There is nothing like a concrete illustration when it is desired to bring home to the makers of automobiles the reasons for conforming to a given standard, and for this occasion the Keystone safety starting handle is used as the illustration. This handle is now a regular part of Alco cars, and its value seems to be adequately demonstrated. It was used on a few of the cars during last year, and was made a regular part of the Alco equipment when the engineers of the company found that it had the two virtues which are necessary from a practical point of view. It is not enough that an equipment will perform a function, so that when the device was first applied and it was found to be capable of performing its function, there still remained the question of ruggedness in service. It took some time to find out just what part would have to be redesigned in order that the equipment as a whole would be stable, and the illustrations here shown are of the final equipment as it is used on Alco cars.

The complete safety starting handle is shown singly at the right of View A, and the component parts are given at the left of the same view. In View A the starting crank is shown rotated 24 degrees to the right of the vertical line, at which point the back kick began in the experiment which was conducted for the purpose of showing how far in the reverse direction the crank would travel before its mechanism would bring it into the release position. In View B the releasing mechanism is just letting go; the angle is 4 degrees to the right of the vertical line, so that the difference between the angle in View A and the angle in View B is the distance of angular travel which must be displaced in order to effect the release of the crank during a back kick. This angle as shown is 20 degrees. In View C the crank stands 8 degrees to the left of the vertical center, which is the position the crank took in the worst case, which 8 degrees represent the point at which the crank jaws are absolutely clear, with no chance whatever of interference between the jaws and the driving pin.

Having shown that the starting crank will release if the motor rotates in reverse, and that the angle of reverse travel is inside of 24 degrees, and that the difference between the point where the crank begins to reverse and the position of absolute clearance is inside of 32 degrees, it is unnecessary to produce any further reasoning with a view to indicating how well the hazards due to back kicks are cared for by this equipment. It is designed for this purpose, and is doing the character of work in practice which makes it wholly unnecessary to more than point out the facts. The illustrations show a starting crank of the usual design, a supporting bracket, crankshaft, a ratchet and a finger with relating small parts. The hub of the crank handle has a groove turned in it and forms a part in the ratchet-like construction. The other part of the ratchet has a drilled hole in which is a steel ball kept in place by a small spring. This form of ratchet works extremely well in practice and is entirely free from backlash. On the relating part of the ratchet is a cam or inclined wedge-shaped piece, located on the inner side, which fits over the finger on the bracket. In cranking the automobile, the handle turns freely in the right-hand direction, and the finger is then at the bottom of the inclined surface, but as soon as the backward move takes place, the cam presses against the finger and forces the handle out of engagement. The extreme movement of the handle is limited by the shoulder at the end of this cam piece.

If safety starting cranks are to be considered desirable in automobile work, it then remains to have automobiles so standardized that they can be applied without having to be especially designed for each make of car, not only for the reason that special designs are more costly, but on the further ground that mistakes are likely to creep in every time a new design is encountered, so that having arrived at a satisfactory basis for the safety starting crank, it remains to so design automobiles that it can be attached to them at will without having to redesign either.

The illustrations here afforded were placed at the disposal of The Automobile by William R. Webster, M.E., of Philadelphia, Pa., who is the inventor of the Keystone safety starting crank, and as it is here shown, it represents Alco practice.

Fuel System of Stearns Model 30-60

Some facts in relation to the gasoline storage and the method of feeding it to the carbureter, showing how it is put under pressure and controlled by a float in the auxiliary tank on the dash, so that it feeds to the carbureter by gravity. The carbureter is of the double-jet type, but one float-bowl serves for both nozzles, and the things to do if the carbureter demands attention are discussed.

DESCRIPTIONS of automobiles, while they afford a certain amount of information, general in its character, even so, the purchaser of a car must either be taught by the maker's representative how to manipulate adjustments, if the necessity arises, or technical papers, if they are to be up to a fitting standard, face the necessity of presenting specific information which may be used in the process of tuning up the automobiles. If purchasers can get from makers' instruction books data which will be sufficiently comprehensive to serve the purpose, it will be a good idea for them to do so, but an instruction book will be of no value at all, unless it is carefully read, and with a further understanding that the instructions and the automobile be compared, so that the purchaser will be sufficiently familiar with the situation to warrant him in making an adjustment on the road.

It is not prudent to undertake to adjust the ignition or the fuel system of an automobile in the absence of familiarity and at a distance from home, with the chances of disarranging the system beyond the skill of the owner to further cope with the problem. If a car will run at all, one unfamiliar with the situation will be justified in undertaking the tuning-up process in some place where he can get assistance if necessary; there is a chance that he might by tinkering with the delicate adjustments so derange the power plant that he will fail to make the motor run at all—assistance will then be necessary.

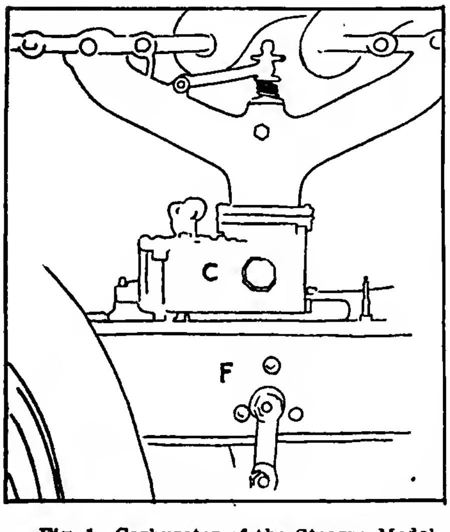


Fig. 1—Carbureter of the Stearns Model 30-60, showing how it is partly below the chassis frame

It would be an ambitious undertaking for a technical paper to present in detail the ignition and fuel system of every automobile made; there are but 52 issues of the paper per year, while of types of automobiles there are upward of 1,000. The great danger in presenting matter to readers lies in giving them too much; it is the old story of the needle in the haystack—there is too much hay. To avoid undue complication, it will be in the path of wisdom to present details of some one system at a time, and even that as briefly as possible.

For this occasion the fuel system of the Model 30-60 Stearns automobile is taken as the subject. Briefly stated, this system comprises:

(A) A gasoline tank located at rear of chassis under pressure.

(B) An auxiliary gasoline tank located on the dash to the right side of the automobile, not under pressure.

(C) A pressure regulator located on the dash under the bonnet just in front of the auxiliary gasoline tank.

(D) A hand pump located on the dash to the left side outside of the oil pump, the two pumps being alongside of each other.

(E) A double-jet carbureter located on the left side of the automobile in a mid-position on the horizontal line of the motor, partially hidden by the chassis frame F, the carbureter being indicated by C, Fig. 1.

(F) Piping which leads from the gasoline tank along the right side of the chassis frame to the auxiliary or dash-tank, which is shown in section.

(G) Piping from the combustion chambers in one of the cylinders of the motor to the pressure regulator, which receives gas under compression.

(H) Pressure pipe leading from the pressure regulator to the pressure side of the gasoline system.

Become Familiar With the Carbureter Adjustments

Referring again to Fig. 1, the carbureter C is placed so low down that it comes behind the chassis frame F for the most part; this was a necessity, due to the fact that the feed from the auxiliary gasolinc tank, which is located on the dash, is by gravity. It was stated that pressure is employed for the purpose of feeding the gasoline from the main tank at the rear of the chassis to auxiliary tank on dash. A section of auxiliary tank, shown in Fig. 2, discloses gasoline feed pipe P1, which leads from main tank to filter F, and as the arrows point, the gasoline supply leads into the auxiliary tank T, through a hole in the top, by a needle valve N; if the float is buoyed up sufficiently to press the needle onto its seat, which buoyancy is due to gasoline in the tank, the needle valve will stop off the pressure when the gasoline level is high enough to raise the float to which the needle valve is attached. The gasoline in the tank does not, therefore, have to be under pressure, and it flows by gravity through the pipe P2 out of the bottom of this tank to the carbureter, as shown in Fig. 3, entering at the top of the bowl B, through the fitting F.

The carbureter is of the float-feed type, so that a copper float, which is inside of the bowl B, stops the flow of gasoline from flowing through the fitting F into the bowl just when the level raises to that of the nozzles in the main housing of the carbureter C. This carbureter has two sets of air passageways, P1 and P2, with a nozzle in each, and air openings, shown as circles in Fig. 3. To vary the amount of air which can enter through the circular ports shown:

(A) Back off the wing nuts W1 and W2 of the smaller of the two bowls, which is marked P1, then slide the bottom casting around, noting the extent to which the holes will be covered by the sleeved portion of the lower casting. The sleeve extends up into the casting P1, and has openings in it which register with the openings in the casting P1, but by sliding the sleeve around when the wing nuts W1 and W2 are backed off, the holes will fall away from their registered position and more or less close up the air passages. When the adjustment is made, the wing nuts W1 and W2 must be screwed up tight again to hold it in place.

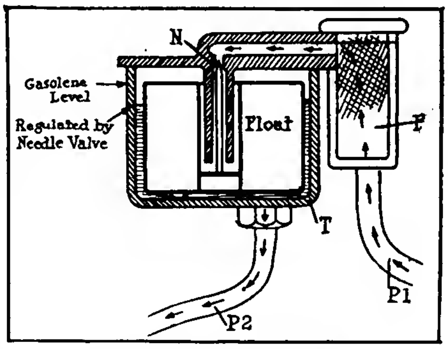

Fig. 2—Section of auxiliary gasoline tank on the dash, and means of limiting the flow of gasoline under pressure by a float.

If it is desired to adjust the air passages of the larger (inside air valve) the wing nuts W3 and W4 (the latter being shown in dotted lines) should be backed off when the passageways in the casting P2 may be throttled in the manner as described for the smaller bowl P1. The operator will have to exercise some care in making these adjustments, and the wing nuts W3 and W4 must be tightened up again when the operation is completed.

The spring S1 at the bottom of the carbureter C, Fig. 3, controls the automatic air valve on the larger of the two carbureters; this spring is very light; the pressure must be carefully regulated; the weight of the valve is almost sufficient to prevent the valve from opening, excepting at the higher speed, when more air is required in order that the mixture will be in the proper ratio of gasoline to air.

The spring S2 on the carbureter C, Fig. 3, is relatively stout and it is placed to hold the accelerator in the closed position. The lever L1 swings in the direction of the arrow when the accelerator foot pedal is pressed, there being a system of links and rods between the foot pedal of the accelerator and the lever L1 for the purpose of imparting the desired motion. The spring S2 must be adjusted to that strength which will keep the accelerator in the closed position against all the forces which are likely to be brought against it, excepting positive pressure on the foot pedal at the will of the operator.

Of the troubles which are likely to be experienced with the carbureter, the most prolific one may come from impurities in the gasoline; should water accumulate it may be run out of the bottom of the bowl B through the drain-cock D; but should the carbureter flood, the cover T over the float bowl B would have to be taken off, which may be done by backing off four screws. The needle valve seat is attached to the cover and will come away with it. The primer valve is also fitted to the cover and will come off with it. With the cover off, the float bowl will be exposed to view, and the needle valve will be found in a hole in the center of the float bowl; the bowl and the valve may be lifted out and by placing the needle valve in the valve seat member, which is attached to the cover, it will be possible to determine if the needle valve is tight by the simple expedient of pressing it against its seat and blowing through the hole in the fitting F. If the valve is not tight it will have to be ground in. It is also necessary to observe if the priming valve is tight on its seat; if it is not the carbureter will flood. The priming valve has a spring on it, and a fork lever L shaped like a bell crank is placed to lift the timing valve off of its seat against the pressure of the spring. It may be that the fork, which engages a washer on the valve stem, will prevent the valve from seating when the valve is supposed to be closed. If this is found to be true, file away enough of the fork to let the valve seat. If the valve stem is battered up so that it will not make a tight seat it must be ground in. It will be possible to note this condition if flooding continues after the needle valve, which is actuated by the float, is made tight.

Before putting the cover T back, clean out the float bowl. If water is present it will not flow through the sieve in the bottom, and it will have to be absorbed by a clean cloth to get rid of it. This is one of the strange things about fine-mesh sieves, chamois skin, and like filters. If the filter is first wetted with gasoline. water will not then flow through, but if the sieve is first wetted with water, gasoline will not flow through. This odd situation may be carried so far as to say that if part of the sieve is wetted with water and another part with gasoline, water will flow through the part which is wetted by water and gasoline will flow through the part which is wetted by gasoline.

It would be a natural assumption that the length of the needle stem, which is placed in the float bowl and is concentric therewith, will be fixed by the maker so that considering the buoyancy of the float, gasoline will raise in the bowl to the proper level to match with the height of the two nozzles in the respective air chambers. Should this not be the case, the carbureter will either flood or it will stop off the gasoline, tending to "starve" the mixture; flooding would be the most serious difficulty, but this might be overcome by placing this piece of cork on the cross bar which prevents the needle stem from passing clear through the hole in the float. The piece of cork would have the facility of raising the height of the stem so that it would press against its seat were the buoyancy of the float below the requirement. If the float leaks, it will, of course, become loggy and fail to serve its end. In this event the hole must be located and stopped up. This might be done with a soldering iron, but in the absence of one in the kit, a match may be whittled to a sharp point, and after enlarging the hole a little, the match may be screwed in tight. If the match is dry when it is screwed in, it will swell when it becomes gasoline soaked and stay in the hole long enough to let the autoist get home with his car.

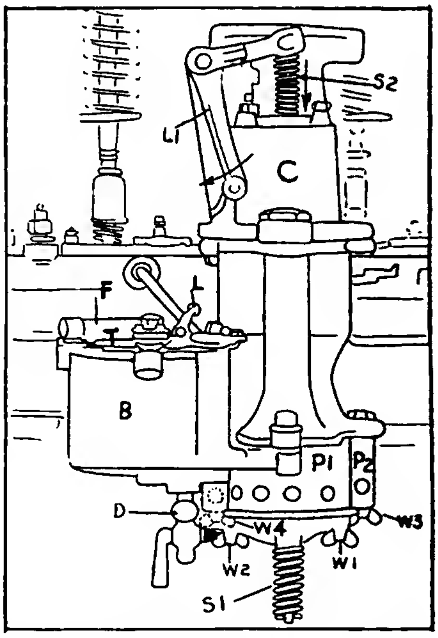

Fig. 3—Carbureter as it would look were the chassis frame removed, with letter references to aid in the discussion.

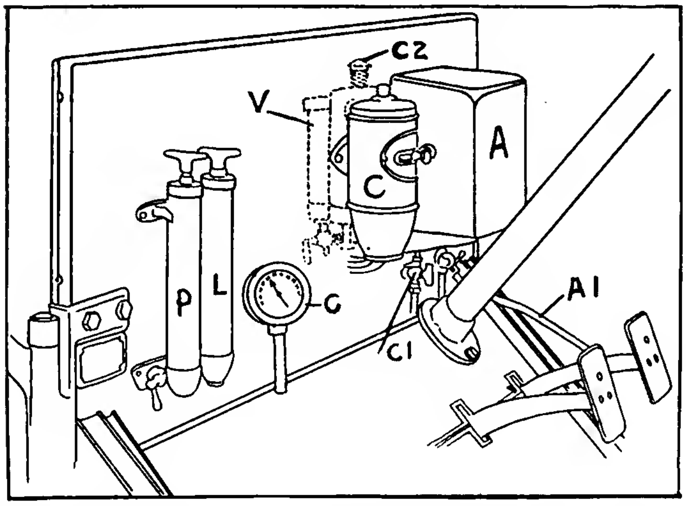

Fig. 4—Dash of the Stearns Model 30-60, showing placing of the auxiliary gasoline tank, pressure gauge, pressure pump, and dash-coil

Become Acquainted With the Dashboard Equipment

Fig. 4 shows the dashboard equipment. A is a mahogany cover over the auxiliary gasoline tank, a section of which is given in Fig. 2. C represents the dash-coil of the Bosch dual ignition system, which was described last week. P is the pump by means of which pressure may be supplied to the gasoline system, and G is the gauge which tells how much pressure is on the gasoline system. V is the automatic pressure valve, shown in dotted lines, it being on the back of the dashboard under the hood , as before stated. A1 is the accelerator foot pedal.

If the pressure on the gasoline system is not sufficient to cause the gasoline to flow into the auxiliary tank A, there will be a shortage of gasoline, but this will be discoverable by opening the cock in the bottom of the tank to see if gasoline flows out. If it does not it will then be known that the tank A is empty. If it is desired to examine the carbureter to the extent of taking off the cover of the float bowl the cock C1 may be closed to shut off the flow of gasoline to the carbureter; if this is not done gasoline will continue to flow through the system out of the

Automobile Law Chart for States Which Regulate

By XENOPHON P. HUDDY, LL.D.

Gist of the automobile laws of all the States in the Union which regulate the use of automobiles through special laws. The information afforded includes the status of non-residents, the legal speed, equipment required, and penalty imposed for a conviction.

COMPLETE, accurate and up-to-date, this chart of the automobile laws of the various states contains the principal and important requirements with which automobilists should be familiar. In those states where non-residents are exempt from local registration, the exemption applies where the automobilist is duly registered in his home state and when he carries his home state number tags and other credentials. The speed rates are indicated in the chart in numbers only, it being understood that the lowest rates apply to built-up sections of cities and villages, the next rate to sections of municipalities not closely built up, and the highest rate to the open country. Automobiles should, of course, be equipped with brakes and a signaling device. As this is assumed, only the provisions concerning lights are given herein. The penalties stated in the chart are indicated in a general way. Those who contemplate traveling in a state which does not exempt non-residents should write and obtain the necessary license. More detailed information in regard to the requirements of the automobile laws may be obtained by writing to the various officials having charge of registering and licensing motor vehicles.

	Registry	Non-Resident	Speed	Equipment	Penalty
Alabama	Probate Judge, 25c.	Not exempt	8 m.	Brakes & muffler	$20 to $200, 1 to 6 mo.
California	Sec. St. $2	Exempt	10 m. 20 m.	2 white L. forward, 1 red rear	$100 to $250
Connecticut	Sec. St. $6 to $30—h.p.	Exempt 10 d.	25 m.	2 white L. forward, 1 red rear	Max. $500 or 1 yr. or both
Delaware	Sec. St. $5	Exempt	12 m. 20 m.	Brakes and horn	$25 to $100
Dist. Columbia	Auto board $2	Exempt 10 d.	12m. W'sh 20m. O.C.	2 white L. forward, 1 red rear	$5 to $250
Florida	Sec. St. $2	Exempt 30 d.	Reasonable 4m. curves, etc.	2 L.	Max. $100 & imp.
Illinois	Sec. St. $2	Exempt	10 m. 15 m. 20 m.	2 white L. forward, 1 red rear	$10 to $200
Indiana	Sec. St. $1	Exempt	8 m. 15 m. 20 m.	"Lighted lamps"	$50 to $200
Iowa	Sec. St. $5	Exempt	12 m. 15 m. 20 m.	1 white L. forward, 1 red rear	$25 to $50 & imp.
Kansas	No state law	Exempt	10 m. 20 m.	1 or more L. forward	Max. $100
Kentucky	No state law	Exempt	15 m.	1 white L. forward, 1 red rear	$10 to $100
Maine	Sec. St. $2	Exempt	8 m. 15 m.	1 L.	$50, 10 d.
Maryland	Com. M. V., $6 to $18—h.p.	Exempt 7 d. sp. permit	12 m. 18 m. 25 m.	2 white L. forward, 1 red rear	$50 to $500 90 d.
Massachusetts	Mass. High. Com., $5 to $25—h.p.	Exempt 10 d.	15 m. 20 m.	2 white L. forward, 1 red rear	$10 to $100
Michigan	Sec. St. $3	Exempt	10 m. 15 m. 25 m.	2 white L. forward, 1 red rear	$25 to $100 and imp.
Minnesota	Sec. St. $1.50	Exempt	25 m.	2 white L. forward, 1 red rear	Not in auto law. See crim. stat.
Missouri	Sec. St. $5	Exempt 20 d.	8 m. 10 m. 15 m.	2 white L. forward, 1 red rear	$25 to $500
Nebraska	Sec. St. $1	Exempt	10 m. 15 m. 20 m.	1 or more white L. forward, 1 red rear	$25 to $50 and imp.
Nevada	Sec. St.	Exempt	10 m. 15 m. 20 m.	1 or more lights forward	$25 to $50 or imp.
N. Hampshire	Sec. St. $10	Exempt 10 d.	10 m. 25 m.	Lamps	$10 to $50
New Jersey	Com. M. V. $3 to $10—h.p.	Not exempt 8 d. sp. license	12 m. 25 m.	2 white L. forward, 1 red rear	$100 to $200
New York (New law in effect Aug. 1, 1910.)	Sec. St. $5 to $25—h.p.	Exempt	30 m.	2 white L. forward, 1 red rear	$100 and other penalties
North Carolina	Sec. St. $5	Exempt	8 m. 12 m. 25 m.	2 white L. forward, 1 red rear	$50
North Dakota	No state law	Exempt	8 m. 25 m.	2 white L.	$10 to $25
Ohio	Sec. St. $5	Exempt	8 m. 15 m. 20 m.	2 white L. forward, 1 red rear	$25 to $100
Oregon	Sec. St. $3	Exempt	8 m. 25 m.	1 white L. forward, 1 red rear	$25 to $100
Pennsylvania	St. H. Dp. $5 to $15—h.p.	Exempt 10 d.	25 m.	2 white L. forward, 1 red rear	$10 to $200
Rhode Island	Bd. of P. R. $5 to $25	Exempt 10 d.	15 m. 25 m.	1 or more white L. forward, 1 red rear	$200 to $500 or imp. 60 to 90 d.
South Carolina	No state law	Exempt	15 m.	1 white L. forward, 1 red rear	$10 to $150 or imp. 30 d.
South Dakota	Sec. St. $1	Exempt	10 m. 15 m.	White L. forward, 1 red rear	$25 to $50
Tennessee	Sec. St. $2	Not exempt	20 m.	Usual L. equipment sufficient	$25 to $100
Texas	Co. Cl. 50c.	Not exempt	8 m. 18 m.	1 light	$5 to $100
Utah	Sec. St. $2	Exempt	10 m. 15 m. 20 m.	2 white L. forward, 1 red rear	Misdemean'r
Vermont	Sec. St. $1, 75c. h.p. sec. reg., 50c. h. p. 3d reg.	Exempt 10 d.	10 m. 25 m.	1 white L. forward, 1 red rear	$50 or 6 mo.
Virginia	Sec. $2	Not exempt	12 m. 15 m.	1 white L. forward, 1 red rear	$10 or 30 d.
Washington	Sec. St. $2	Not exempt	12 m. 25 m	1 or more white L. forward	Max. $100
West Virginia	Auditor	Not exempt			
Wisconsin	Sec. St.	Exempt	12 m. 25 m.	1 white L. forward	$10 to $25

Tells of Good Roads' Importance

SOUTH BEND, IND., June 13—Three hundred or more good roads enthusiasts, including highway commissioners from every township in Berrien county, prominent farmers and others, met last week in Benton Harbor, Mich., and heard good talks on good roads and the manner of constructing them. The meeting was held under the auspices of the Berrien County Good Roads Association.

Lengthen Course for Grand Prize

On account of urgency and number of requests that have been made of W. K. Vanderbilt, Jr., president of the Motor Cups Holding Company, promoter of the Grand Prize race of the Automobile Club of America, to lengthen the course for the big event, the company has decided to make the course 379.2 miles instead of 278.08, as was announced at the beginning of the season. The race will be held October 15.

ATLANTA, June 13—Below the shadowy line of Mason and Dixon, that arbitrary boundary which has always carried with it so much of significance and in this day so much of mystery and romance, the automobile club, as it is known in the North and East and West, is practically an unknown quantity save for such shining example as that set by the Atlanta Automobile Association and a very few other similar organizations.

The reason for the scarcity of automobile clubs in a section as rich, potent and progressive as the South, where social organizations and business associations are so notably complete and efficient, is a little obscure until one views the subject from the standpoint of the South itself. Below the Mason and Dixon line the motor car's invasion has been too recent to allow of sufficient time to form real clubs, except in a few instances like the subject of this sketch.

The conservatism of the South is expressed in its club life in speaking terms, as is evidenced by such organizations as the Pickwick and Boston Clubs of New Orleans, the Piedmont and Capitol City Clubs of Atlanta, the Watauga of Nashville and the Pendennis of Louisville, as well as such associations as the world-famed Washington Artillery of the Crescent City. But the vogue of the motor has swept over the South, and as a result here and there organizations of motordom are beginning to make their appearance. One of the pioneers in this line of activity is the Atlanta Automobile Association, which has for its object the advertising of Atlanta through the medium of the splendid speedway that has been installed near the "New York of the South."

The idea that lay at the base of the association was to place the city of Atlanta before the attention of the world. After studious consideration of all the ways and means that would be likely to accomplish this result, the men who are behind the organization decided that a speedway of the highest type would answer the purpose better than anything else, and thereupon they set about securing the land necessary for such an enterprise.

Their preliminary plans showed that 302 acres were required for the track and its buildings and not an inkling of their purpose was allowed to leak out until all the land had been rounded up and irretrievably placed under contract.

The impression was given out that a new cemetery was projected, to account for the purchase of the small farms that constituted the bulk of the desired property. The plan was to hold a race meeting during the week of the first automobile show of the South last fall, and as the movement did not really get under way until May 1, 1909, some extremely quick action was required.

Atlanta is a lively city, a metropolis of its section, but it is only number forty-three in the list of American cities as far as population is concerned. So it took a high quality of nerve to undertake such a project as that of installing a great speedway. However, the men behind the movement were intensely civic. They figured that if the race meetings made some money, so far so good; but if the balance sheets showed a loss it could be written off against an immense credit of advertising for the city. They were amply able to stand a loss in such a cause.

Securing the land commenced May 1, 1909, and was finished June 10. Bids were asked immediately, but some of the largest contractors in the country declared that the work could not be done in the short time that remained before the dates of the proposed meeting. At last one contractor said he would undertake the job if there was no rock work in the excavation. He was given a free hand and with a giant force of steam shovels, railroad trains and mule and man power he was able to complete the job within the time limit.

Atlanta was full of tourists at the time of the big show and the five-day race meeting, really the opening of the speedway, proved a vast success from every viewpoint. Numerous records were broken and several new world's marks were set. The attendance was enormous and not a life was sacrificed.

This spring the race meeting was not a success, but plans are now being laid to make the coming fall meeting the greatest thing of its kind ever seen in the South.

Stock in the association was offered to the general public, but the response was not of sufficient volume and Asa Candler, Sr., one of the most progressive citizens of the South, dug down into his own pocket to make up the deficiency. The organization contains the names of many of the most prominent men of Atlanta, who have given freely of their time and money to make this enterprise a success.

Aside from the speedway and its appurtenances, the association has a neat little clubhouse, tastefully fitted up for social features. After the recent spring meeting the prediction was made with more or less freedom that the Atlanta Automobile Association was dead. Such was not the case. An absolute loss in any business enterprise is disagreeable, but the men behind the association did not figure it a loss when they were obliged to make up the deficit. They considered such payments merely in the light of liquidating an excellent advertising bill.

But for the coming fall meeting nothing but success can be seen. Everybody is enthusiastic about its prospects and the whole association is working as a man to insure a large and representative entry list and a giant attendance during the races.

It is always refreshing to discover evidence of civic pride and progressive spirit and the motive of this association in making the Speedway project possible may be described as both. The object it sought to attain was wider than the automobile or the city of Atlanta—it was aimed to bring about the general welfare and commercial advancement of the whole of sunny Dixieland. And in passing it may be noted that it has accomplished much in that direction.

The good work done by the Atlanta Automobile Association and the stimulation to motoring given by the Good Roads and Glidden Tours through the South this spring have resulted in much activity in that line. But the honors of the pioneer must be laid at the feet of the enterprising, active and intelligent Atlanta Automobile Association.

Coming Events in the Automobiling World

June 20-July 6....Detroit, Mich., Industrial Exposition, Detroit Board of Commerce.

opposed by poverty-stricken
of resistance to the onward march
s its balance wheel, and compels
ry croaking which greets the car
l machine which races into the
look well to its mainspring and to
profusely lubricate all the working parts; the proprietors of musicless tones, like the comets which fall upon the velvet-like envelope of earth, do more good than harm; they are crisped to dust as they ricochet from billow to billow, but the energy they possess is absorbed by the surroundings, and warmth, which is life, is taken up by the body which receives the blow.

* * *

Antiquity holds in the hollow of its withered hand the foundation of all progress. The first wheel, as it is pictured here, just as it was uncovered in a mummy-pit at Nineveh, 2000 B. C., is the rude prototype of the wheel of the very automobile which causes rare comment to-day. Would the originator of that wheel have listened to progress as it has taken on its present garb? No. The wiseacres who gathered around the throne of the Pharaoh of that day would have pointed out that ruin was concealed in every fiber of a pneumatic tire.

* * *

History justifies antiquity, but the antique has no place in active life—it belongs in a museum.

* * *

Shall we quake with fear because the automobile industry has accumulated force which is worth $500,000,000 per annum? Is progress an asset or a liability? If an asset, is it possible to have too much? If a liability, how comes it that the world has extended such liberal credit?

* * *

Considering the fact that the demand for steel as used in automobile work is 133,000 tons per year at the present time, and that this steel comes from the same hole in the ground as that which goes to make steel rails, knives, baby carriages, and bridges—allowing that mine labor is paid for its hire in either event—what kind of logic is it that says there is danger in mining the raw material for this particular 133,000 tons of steel?

* * *

Remembering that $160,000,000 worth of machine tools are now being utilized in the automobile business; that they would not have been in demand without it; that it took 43,000,000 man-days to build these machine tools; and that money was paid to all this labor—was it imprudent to employ the labor?

Allowing that 40,000 freight cars will be but enough to accommodate a year's output of automobiles during transportation, is it a risk for the railroad companies to furnish them?

* * *

In the plants where freight cars are made labor is employed, and the question is, Were the men in general work, or doing automobile work when the 40,000 freight cars were being made? Just think of it—4,800,000 pneumatic tires are made and used in a single year, all because of the automobile. This small effort requires the expenditure of $100,000,000 or more per year; is it imprudent to pay the cotton growers for their product? Will the negroes in South American wildernesses be hurt physically or morally by the opportunity to earn sustenance? Are the American artisans who make an honest living building tires damaged beyond repair by the money they thus receive?

But the story is not half told; as a small part of the situation, 1,000,000,000 gallons of automobile gasoline are consumed in a year; a small matter of $14,000,000. The question is ripe for the asking: Is Standard Oil money a menace to the community?

* * *

We build roads; what for? In order that automobiles may be used to advantage, and to realize the greatest measure of economy, remembering that the automobile and the road on which it travels constitute the complete conveyance—not the automobile alone. Are the roads, since they are in all truth but a part of the automobiles, wrong to have?

* * *

Is the farmer who uses the road justified in demanding that it be suppressed merely because it is a part of the automobile.

* * *

The building of automobiles, and their use in commercial pursuits, will deprive the farmers of the horse market they have enjoyed ever since women were released from the task of drawing coal out of the mines of Wales and the plow in the fields. Will this be an economic wrong? If so, why was it not wrong to substitute horses for women? We still have quite a few women with us; why allow them to rest in idleness?

* * *

Will the farmers be damaged if farm labor is commandeered?

* * *

Is the farmer so dull that he will not be able to employ the same farm labor indirectly and to better advantage? Is he not clever enough to see that he will get more out of the labor in this indirect way than would be possible directly?

* * *

Is it not true that a laborer can grow more wheat running a lathe in a shop than he can pushing a plow (in the old way) in the field?

* * *

If the laborer proves to be a better man at growing wheat on a lathe—in a shop, so to speak—than he could in the old way, will he not be in a position to purchase more of that wheat for his own use?

* * *

In a word, is money absorbed from other industries by the automobile industry, as the learned are wont to proclaim, when, as a canvass of the situation shows, the building of automobiles adds to the sum total of energy in the world? Energy is made valuable to man in his environment when it is lifted up by activity from the sea-level of inactivity, and placed alongside of other kindred forms of energy.

* * *

Were the automobile a plaything all the energy put into it would be put into play; would there then be too much play? Who can tell? We earn the right to play when we work.

But the automobile is not a plaything; it is the next step on the great stairway of human progress. Let us climb down the stairs of progress right now, and learn, perchance, wherein the error, if one there is, lies.

6000 to 4000 B. C.—Medians, Persians, Assyrians and Egyptians managed to drag burdens placed across the forked branches of a felled tree.

5000 to 3000 B. C.—The same peoples built sledges and rolled them on logs. Tiles show funerals with white oxen drawing the corpse on these conveyances.

4000 to 2000 B. C.—The Egyptian **plaustrum** is a cart on two solid wheels, drawn by horses.

2000 to 1000 B. C.—The Scythians, being nomadic, placed their huts on wheeled platforms and toured through Asia Minor.

Homer describes Juno's carriage by its "whirlwind wheels on iron axles, each with eight brass spokes."

1000 B. C. to our era.—Plinius reports that the chariot on four wheels came from the Phrygians before Rome was founded.

The oldest Roman vehicle, the **arcera**, mentioned in the Twelve Tables, was an ambulance.

Solon, the founder of Grecian law, ordered that no good woman should leave her house at night, unless in a carriage lighted by torches.

Cæsar went from Rome to Gaul in one week by relay coaches, but he issued an edict ordering moderation in the luxurious equipment of the litters employed by ladies.

The Etruscans are credited with the introduction of hoods for chariots.

0 to 300 A. D.—At the beginning of the Roman Empire the four wheeled carrucca, with seats for two only, was the gala vehicle. The driver sat in front and lower. This word is the origin of "carriage." The **pilentum** was an open city carriage for matrons. It had a canopy on four slim posts worked in gilt bronze, ivory or rare woods. Young girls sat in highly ornamented litters covered with drapes. Only women of bad reputation were prohibited by law from using conveyances of any sort. The **carpentum** looked like a richly carved baker's delivery wagon, and was drawn by two horses tandem when used by women, by four horses when used by men. It had either two or four wheels. The Roman **cisium** was a cabriolet hung by leather straps.

Middle Ages.—In the ignorance and poverty of the Middle Ages the use of vehicles languished. The use of leather straps for suspension was forgotten. Only the **thensa** survived. It was a two-wheeler used by the Romans for transporting the images of the gods, and was built in imitation of temple style, with columns, pilasters, etc. It was used for wheeling the images of the saints. Later all sorts of rough carts reappeared.

1294 A. D.—Philip of France made a sumptuary law prohibiting plain citizens from using carriages. Pope Gregory possessed a **caretta**, looking much like a prairie schooner. It was drawn by two horses tandem. Richard II. of England and some of his friends had **whirlicotes**.

1554 A. D.—Queen Mary went to coronation in a canopied chariot. The English sedan chair of 1581 was on wheels and much like a push chair for invalids. This century saw the introduction of leather braces again, the innovation coming from Hungary. Ladislaus of Hungary sent such a carriage as a present to Charles VII. of France.

1650 A. D.—Glass windows were introduced in French carriages.

1670 A. D.—**Steel springs were introduced at about the same time** in France and England. Charles II. formed the first Coachmakers' Company in 1677. A pamphlet was published in France extolling the virtues of carriages as against those of sedan chairs. **Cabriolets** came in 1672 from Florence, Italy. **Postchaises**, looking like sedan chairs on wheels, came at the end of this century.

1670 to 1700 A. D.—On the Continent the **Berlin** was the favorite type. It was a coupé sitting on the middle of long poles or springs reaching from front to rear wheels. The high driver's perch came in use through the **chariot à l'Anglaise**, at the same time as the landau, which looked like a modern coupé, but could be opened.

18th Century.—The high perch **phaeton** was used by young bloods of the George III. period. The **brlska** was on C springs with leather straps and remained in fashion into the early Victorian Era.

1804 A.D.—Obadiah Elliot patented elliptical springs. Napoleon's campaign carriage had bedroom and library and was a real military touring car drawn by two or four horses, sometimes by six.

1834 A. D.—The **hansom** was patented by Hansom of England.

With these dates available, which are offered to facilitate matters, it is hoped that the wise will point to the particular epoch back to which we are to go in quest of safe and sane finances, counting as the cash-box relates to methods which eliminate burdens that weigh down the part of the human race which is least able to resist. But why should idle cash be the gauge by which active men are to regulate effort; is the right to produce limited by the belief that money may spread out too thin in satisfying demand?

Two Hundred Cars Participate in Premier Roadability Run

PHILADELPHIA, June 13—Two hundred cars participated in the second annual roadability run of the local Premier representatives to Cape May on Saturday afternoon last. Of these, fully two-score came from New York, the itinerary of the latter contingent including a return trip as escort to the contestants in the Atlanta-New York Good Roads Run, who arrived here from Gettysburg yesterday. On the trip to Cape May, additional Premier cars joined the procession at Vineland, Bridgeton, Cape May Court House, and other points, and when the big line swung into Cape May there was much enthusiasm along the route to the big Hotel Cape May, the official headquarters.

Allen Shelden, president of The Motor Company, local Premier agents, was the host of the occasion. The mayors of this city and of Camden were among the guests.

The New York contingent left the metropolis on Friday morning, and had a veritable mud plug across Jersey to this city. The Gotham section was under the direction of R. M. Owen & Co.

There was a grand parade of all the cars in Cape May on Saturday night, and much red fire was set off to celebrate the occasion. A grand ball wound up the festivities, after which the prizes were distributed to the winning drivers. The Boards

Official Car of the New York Premier Contingent

of Trade of several of the larger towns along the route hung up cups for the car whose time most nearly approached the secret official figures established for the run to their respective cities—these in addition to the main trophies. Those who won these various cups and trophies were:

L. W. Mulford, of Narberth, Pa., the Vineland trophy. Official time, 99 minutes; actual time, 99 minutes, 10 seconds.

W. J. Hendren, of Manayunk, the Bridgeton trophy. Official time, 175 minutes, 44 seconds; actual time, 175 minutes, 24 seconds.

Benjamin J. Carroll, of Philadelphia, the Port Elizabeth trophy. Official time, 232 minutes, 36 seconds; actual time, 232 minutes, 40 seconds.

George Thompson, of Philadelphia, the Bellevue Hotel of Court House prize. Official time, 313 minutes, 34 seconds; actual time, 313 minutes.

C. H. Clinton, of Philadelphia, and L. N. Shakespeare, of Haverford, tied for the Cape May Hotel prize, the main trophy, each negotiating the route in the same time—365 minutes, 31 1-2 seconds; the official time was 365 minutes, 30 seconds.

John C. Cave, of Philadelphia, the Board of Trade prize. His time was 365 minutes.

This morning the New York Premier brigade followed the Atlanta-New York tour to the metropolis.

One peculiar feature of the run was that the weather, which in other not distant sections of the country caused the abandonment of several important events, was most delightful. When the

Line-up on 59th Street, New York, Before Start

tourists arrived at Cape May the sun was in evidence and had been for the greater part of the day.

Allen Shelden, the director of the run, who was largely instrumental in inaugurating the annual outing, was complimented for the thorough preparations he had made for the en-

New York Premierites Checking Out at Jersey City

tertainment of the more than 750 guests who composed the party. Fully two-score newspaper men were included in the number, no less than 10 cars being detailed to carry the writers.

News Notes from the Kentucky Metropolis

LOUISVILLE, KY., June 13—The first run of the season was held here on June 2 under the auspices of the Louisville Automobile Club, when Louisville motorists toured to Frankfort to witness the dedication of the new State capitol. The start was made at 7 o'clock in the morning near the entrance to Cherokee Park, where the cars had assembled. Roads between the two cities were in splendid condition.

Reo Plant to Be Greatly Enlarged

LANSING, MICH., June 13—Another expansion of the Reo Motor Car Company, both in the variety of the output and in the size of the factory, is in prospect. Portions of the old Bement plant, recently purchased from the Detroit Trust Company by R. E. Olds, are to be used as an auxiliary plant for the production of automobile trucks. Two styles of trucks will be turned out this year, one a light delivery wagon for laundries

iiant's Despair Hill Climb

Fifty thousand people cheered when Ralph DePalma, driving his big 200-horsepower Fiat, established a new record for the hill in the free-for-all. The new mark that he set is 1:28 2-5 for the 5,700-foot course, which has grades which at places are as great as 22 per cent. and sharp and dangerous curves at the Devil's Elbow, the Mountain House and the S turn beyond. He was the choice of the people for the record-breaking, owing to the power of his machine, and the crowd showed its appreciation when it learned that he had lowered the record 3 1-5 seconds.

The largest crowd that ever witnessed a climb up the hill lined the course. Automobilists came from all sections of eastern Pennsylvania, lower New York State and northern New Jersey and thousands of machines were parked on the mountainside.

The free-for-all was the event of the day and twelve cars entered it. The Fiat, conceded to be the winner, proved that the judgment of throng was right, while the Chadwick, driven by Len Zengle made great time up the hill and took second place in 1:37, the "Knox Giantess," with Disbrow at the wheel, was a little more than eight seconds slower and won third place. These two cars also maintained their respective positions in the invitation event, a sort of consolation for the drivers who did not win in the free-for-all, and from which the champion Fiat was barred. Zengle took first place in the invitation by daring driving around the sharp curves and by getting great speed out of his car in the straightaway, making the climb in 1:37 3-5, practically the same time as he made in the free-for-all, while Disbrow, with the "Knox Giantess," got to the top in second place in 1:44 3-5. A Matheson Six car won third place.

The famous Hollenback $1,000 trophy was won by Fred Belcher, who drove a Knox runabout, and who went up the hill like a demon, striking the curves with great speed and bounding over the steep finishing stretch to the top in 1:53 2-5. A Knox car also won the event last year, and if a Knox wins it again it will become permanent owner of the trophy. The Knox people took a large space of the prizes for the day too, getting three firsts out of nine events, two seconds and a third. In the Hollenback the Matheson Six car, which Wilkes-Barreans so earnestly hoped would win as it is manufactured here, took second place in 2:00 4-5, while Kincaid's National "40" was third.

Hamilton Beat Express Train to Philadelphia

Traveled 175 Miles Through the Air

Hamilton flew from Governor's Island, New York, to Philadelphia—Returned the same day—Weight was 74 pounds more than Curtiss was encumbered with in his flight from Albany to New York City—Hamilton had some ignition trouble in his return trip—He descended at South Amboy, N. J., on way back and splintered the propeller—New York Times and Philadelphia Public Ledger put up the prize—Public speculating as to the future of the aeroplane.

TRAVELING 175 miles through air, Charles K. Hamilton sailed from Governor's Island, in New York harbor, to Philadelphia and return in safety Monday. He used a Curtiss biplane of the same general character as that in which Glenn Hammond Curtiss recently flew from Albany to New York, but which, it was announced, weighed 74 pounds more than the machine used by Curtiss.

Hamilton's trip was accomplished without an untoward incident until he had nearly completed it, when ignition troubles in two of his cylinders caused him to descend in a swamp-meadow near South Amboy, N. J., where in making a landing he splintered one of the blades of his propeller and was obliged to make extensive repairs before continuing his voyage to the starting point.

This, however, was done after considerable delay and the aviator scudded across the Jersey lowlands and out over the broad reaches of New York harbor in the gathering gloom, reaching Governor's Island just before the lowering clouds and the darkness of night closed in upon him.

The trip was a record-breaker in some respects. It was the first round-trip ever undertaken with an aeroplane between two big centers of population. It involved passing over heavily populated areas, covered with large buildings which produce air-currents and eddies likely to disconcert the aviator. It all seemed ridiculously easy and simple until the very moment when vast crowds assembled about bulletin boards all over the country were ready to cheer the announcement of the successful completion of the flight. Then came a delay that lengthened into minutes and for nearly two hours no word of a definite character was received from the air sailor.

Even those who promoted the flight did not know what had become of Hamilton and his machine and all sorts of rumors were afloat as to their fate. Then came the news of the descent in the Jersey swamp and something like a groan of sympathy arose all over the land.

The start was scheduled to take place at 7 o'clock in the morning from the "made-ground" on the south side of the island and in spite of hazy weather conditions that promised rain and, perhaps, wind later in the day, Hamilton completed all his arrangements, and a few seconds after 7 o'clock gave the signal to let go. With a rush the machine started, but in tilting to leave the earth, the wooden propeller caught upon a stake and one of the blades was splintered beyond repair.

Fig. 1—Starting from Governor's Island on the long flight to Philadelphia

Glenn H. Curtiss volunteered to lend Hamilton the propeller that he had used in his Albany-New York flight, and in half an hour the aeroplane was ready for the trip, equipped with the Curtiss propeller. At 7:36 the actual start was made and the biplane rose gracefully and sailed toward the Statue of Liberty on Bedloe's Island. Then the aviator swerved to the right and crossed the bay in the direction of South Elizabeth.

Vast throngs lined every available point of vantage to get a glimpse of the aeroplane, the route being black with humanity practically all the way to Philadelphia. At an elevation of from 400 to 1000 feet or more, the out-bound trip was made with surprising steadiness. Rahway, Metuchen, New Brunswick, Monmouth Junction, Princeton Junction, Trenton, Bristol and Holmesburg Junction were passed in order and at 9:26 o'clock Hamilton swooped down upon the spot selected for his landing

Fig. 2—After the involuntary descent near South Amboy; carrying the plane out to a road

within the precincts of Philadelphia. Before he came to the ground, the aviator gave an extra exhibition of his facility in handling the machine, circling the field and dipping and rising at will amid the stunning applause of 100,000 persons.

The landing was made without accident, the flying time for the trip of 86.1 miles being 1 hour and 50 minutes.

The aviator delivered a message of greeting from Governor Hughes to Governor Stuart, of Pennsylvania, who was among the first to congratulate the young air sailor on the success of his daring trip. In return he was charged to deliver a message from the Pennsylvania and Philadelphia authorities to Mayor Gaynor, of New York, and the New York State officials.

Hamilton announced that he would start on the return trip within an hour and tore himself away from his host of admirers long enough to provide himself with a cup of coffee and some light refreshments.

In speaking of the first part of the trip he said that it had been without incident practically all the way, but that when he was approaching Philadelphia he noticed that one of his cylinders was missing fire. The motor was pretty well warmed up and gasoline and lubrication supplies were low. Hamilton complained that the quality of his oil was not exactly right and subsequent events showed that the trouble he experienced with foul sparkplugs might be chargeable to that fault.

It was a little over two hours before the aviator was ready to commence the homeward bound flight, and with his machine in apparently perfect condition Hamilton took his seat and gave the signal to start at 11:33 o'clock.

A mighty cheer greeted man and machine as the powerful engine gathered headway and rose above the heads of the crowd, turning to the right to pick up the Pennsylvania Railroad tracks.

The man-bird rose higher than on the first stage of the trip and settling into a fast pace shot northeastward toward the metropolis. Passing Bristol Hamilton threw out a number of peace-bombs, paper projectiles intended to demonstrate the efficiency of the aeroplane in times of war. These little packets rattled down about the heads of the spectators and gave significant promise of what might be the result of that variety of warfare in the next great campaign.

If the crowds were dense on the out-bound trip, those that stood and waited for a sight of Hamilton and his machine on his return voyage were of vastly greater proportions. It is safe to say that there has not been so much excitement in Trenton, the capital of New Jersey, since that Christmas Day about 135 years ago when Washington crossed the Delaware river and surprised the Hessians in their beds. Over the spots where the Hessian mercenaries had their camps and batteries Hamilton strewed another installment of peace-bombs, showing how much easier it would be for him to destroy a hostile army, single-handed, than it was for Washington to accomplish the same result by the military achievement that stands in history as one of the most astonishing feats of any war.

Fig. 3—Near a wood, ascending to clear the trees and to make time

Shooting past Princeton Junction, within sight of the historic university, the aviator took to the meadows south of the railroad tracks and with a sparkling burst of speed moved straight and steadily as far as Metuchen. It was a few miles back that Hamilton first noticed that a cylinder of his engine was missing again, and as he passed over the city he discovered that even with full throttle he could not get an explosion from that cylinder. In a moment another cylinder began to act badly and the aviator curved away from the railroad and was lost to sight over the Jersey lowlands and tidal flats. He found that it was doubtful if he could retrace his course on six cylinders and started to make an airline shoot toward Governor's Island before his power failed.

The sooting of his sparkplugs proved to be too serious, however, and the aeroplane sank lower and lower under the slackened power until the aviator was forced to make a landing. Some distance ahead of him, and in a territory with which he was not familiar, Hamilton discovered what seemed to be a grassy meadow, flat as a board and without obstruction of any kind. With a last effort he applied all the power his dirty motor could generate and, setting his gliding planes, shut off power and came down. The landing was made in a grass-covered swamp that looked like a meadow from above but which in reality was knee-deep in water and mud. The tough swamp grass searched the machinery, and when the aviator tried to disentangle it he found the propeller jammed so hard at its bearings that it became disabled. In a short time assistance came for man and machine and soon the aeroplane was lifted and carried to dry ground.

Messages were sent to Hamilton's family and the officials at Governor's Island and with all despatch another propeller was started toward the scene of the mishap. This arrived after several hours of unavoidable delay and was installed by a force of volunteer mechanics. With his sparkplugs clean once more he managed to make the final ascent of the trip, clearing the trees and crowds and rising only high enough to avoid the obstacles. The rest of his trip was without special incident.

The distance traveled on the return trip was 88.9 miles. The full distance of the round-trip was 175 miles. He started at 7:36 o'clock in the morning and returned at 6:40 o'clock in the evening. His flying time was 3:34, or an average of a little over 49 miles an hour for the entire flying time. On the outward trip he averaged 46.92 miles and on the return 51.36 miles an hour.

The flight was the result of an offer of a big prize by the New York *Times* and Philadelphia *Public Ledger* for a flight between the cities.

Technical Angle of the Hamilton Flight

Mr. Hamilton's flight from New York to Philadelphia and return was made possible by favorable weather and it was interrupted, it is said, through the sooting up of a sparkplug. Are any inferences to be drawn from either the substantial success of the trip or from the little incident which marred it toward its close? According to the best information, the fracture of a propeller blade, which also delayed the returning aviator, was due to unskilful handling of the machine by outsiders after it had landed. The distance of the flight and the time the machine was in the air have no bearing on design or construction, if it is assumed that the weather was uniformly propitious, but they do relate to motor construction or motor operation, owing to the thermic factors which enter at this point. It is usually conceded that sparkplugs very rarely give out under the best motor conditions. Poor lubricating oil would affect all the sparkplugs alike, unless the thermic conditions in one cylinder differed from those in the other cylinders. The inference would be that the motor was operated too close to the thermic limits, and that one cylinder, for some minute reason ultimately due to this general cause, developed so much heat as to "crack" the lubricating oil, preventing its complete combustion. A contributory cause to this effect would be the extra weight carried, in the form of a large gasoline supply. This compelled the aviator to use a high tilt, and the desire to make speed with high tilt compelled the operation of the motor at a high development of power, at which any imperfections in its thermic action and the efficiency of the cooling provisions would be accentuated.

Fig. 4—Greetings between Hamilton and his mother, with sympathetic onlookers

Owing to the persistent rain, the Oldsmobile owners' reunion at Empire City race track Saturday was smaller than its indications promised when all the plans had been completed. About 200 cars paraded from Olds headquarters at Fifty-first street and Broadway to the track where the exercises were to have been held. A. C. Stem proved the winner of the automobile offered free to the holder of the ticket drawn last from a secret receptacle. Aside from luncheon and the running of a foot race, the original program was not followed. The six races carded for the afternoon's sport were called off and the prizes, consisting of silver cups and blue ribbons, were awarded by lot

Society of Automobile Engineers Adds Members

Coker F. Clarkson, General Manager of the Society of Automobile Engineers, this week announced the election of the following new members of the Society: David Dwight Rowlands, Rider-Lewis Motor Car Co.; Clarence W. Spicer, Spicer Manufacturing Company; Christian Girl, Perfection Spring Co.; Arthur Holmes, H. H. Franklin Manufacturing Co.; Marcus Thompson Lathrop, Halcomb Steel Co.; Henry C. Wilson, Sub-Target Gun Co.; C. E. Reddig, Columbia Motor Car Co.; Joseph P. Lavigne, Lavigne Mfg. Co.; Edward R. Hewitt, Hewitt Motor Co.; Tracy Vere Buckwalter, Pennsylvania Railroad; H. P. Dodge, Ohio Electric Car Co.; H. C. Colburn, Colburn Automobile Co.; Irving W. Adams, High Frequency Ignition Coil Co.; John A. Mathews, Halcomb Steel Co.; W. H. Cameron, Willys-Overland Automobile Co.; Charles Archibald Ward, Pittsburg Motor Car Co.; Lars G. Nilson, Nilson-Miller Co.; Hugo C. Gibson, Requa-Gibson Co.; William Fleming Abel, Halcomb Steel Co.

Boston Show Dates; New Car Plant

Boston, June 13—Boston's next motor show will be held during the week of March 4-11, 1911. This was one of the things decided at the meeting of the Boston Automobile Dealers' Association. The election of officers resulted as follows: J. M. MacAlman, president; J. S. Hathaway, vice-president; F. A. Hinchcliffe, treasurer; Chester I. Campbell, secretary; directors, J. W. Maguire, E. A. Gilmore, F. E. Wing, C. F. Whitney, Charles E. Fay, A. P. Underhill and the officers named above. Mr. Campbell was chosen manager of the show.

Plans for the Orson plant, at Springfield, are rapidly crystallizing. It is stated that some $75,000 worth of machinery is on the way in addition to the big shipment already received. It is said that the first car will be finished sometime in July. From what has been given out, it is claimed that the Orson will have no less than 45 ball bearings; have mechanically oiled-valve stems; one-piece housing for the steering gear and some other features that will be entirely new. The horsepower is not stated. Nor has it been intimated what its makers may do relative to the Selden license.

H. B. Layman, formerly with the Packard, Winton, Alco and Ruttenburg plants, is president and general manager, with J. E. Davey, formerly with the Locomobile Company, as factory superintendent. Among the men interested in the car as stockholders, it is said, are W. K. Vanderbilt, Jr., Henry O. Havemeyer, Jr., James Stillman, Percy Rockefeller, Richard Sutro, Charles Gates and other well-known New York bankers. E. C. Kilbourne, of Springfield, a brother of Vice-Pres. H. M. Kilbourne, of the City Bank in New York has been named treasurer of the new concern.

Central Ohio News Features

Columbus, O., June 13—An elaborate system of parks and boulevards is projected by the residents of East Columbus; consequently plans by which to meet the expense of the improvement are now being made. Property owners along Alum creek have been asked to donate enough ground for the desired drives. The matter of improvement has been discussed for some time without obtaining results. Finally, an Improvement Association was formed, with O. A. Miller as president, Dennis Kelly, George Hardy, C. E. Richards and others as officers. It is proposed to raise $25,000.

At a special meeting of the Athens Automobile Club, held recently, the working committees for the coming year were appointed as follows: Laws and Ordinances, C. D. Hopkins; Grievance, H. D. Henry; Streets, Roads and Signs, A. A. Wolfe; Runs and Tours, F. B. Phillips; Membership, W. F. Mercer; Auditing, F. L. Alderman. Six new members were received into the club. Arrangements will be made for a number of club tours.

The Al-Ton Motor Accessory Company, Akron, O., was incorporated with a capital stock of $50,000 to make and deal in motors and motor parts. The incorporators are Clyde S. Pelton, H. T. Maranville, Edward W. Brouse, C. H. Maranville and Harry William.

The Perfect Tire Company, of Cleveland, was incorporated with a capital stock of $50,000 to make automobile tires and motors, and to deal in automobile parts. The incorporators are M. J. Kirby, William Eynon, Walter C. Eynon, W. A. Mayer, Frank L. Smith and Jacob Boeple.

The Charles Schiaer Motor Car Company, of Columbus, O., has taken the Central Ohio agency for the Everett. The territory includes about fifty counties in Central and Southern Ohio.

If plans which are under way are carried out Akron will have another large concern for the manufacture of automobile tires as well as rubber goods of every description. The Portage Rubber Company, of Akron, incorporated some time ago with a preliminary capital of $10,000 is the nucleus for the concern. Steps were taken recently to increase the capital stock to $1,000,000 and a board of directors was elected consisting of William Christy, John Kerch, John W. Miller, Judge Dayton, A. Doyle, A. S. Mottinger, James Christy, M. S. Long and H. A. Kendall, the latter of Cleveland.

A number of sites for the erection of the plant are under consideration and a deal will likely be closed in the near future. It is the intention to start the erection of the plant as soon as possible. At the start 300 men will be employed.

The annual outing given by the Diamond Rubber Company, at Akron, to its thousands of employees took place Saturday, June 11, at Silver Lake Park. Between 10,000 and 12,000 attended the affair.

News Mems. from the Missouri Metropolis

ST. LOUIS, June 13—The route for the three-day run of the St. Louis Manufacturers' and Dealers' Association on June 28-30 has been selected, and details for the contest are fast being completed. The run will be from St. Louis to Hannibal for the first night's control, from Hannibal to Mexico, Mo., for the second night's control, and from Mexico to St. Louis the third day. The distance is approximately 400 miles. The tour covers one of the best parts of Missouri. Originally it was planned to cross the river from Hannibal into Illinois, but the Buick pathfinding car demonstrated that the contemplated route was too long for a three-day run. The honor of being the first entrant and obtaining position No. 1 fell to the Lindsay Motor Car Company, which entered an Interstate car. There will, it is expected, be from 60 to 70 cars in the run. The numbers will be assigned according to the priority of the entry. The small numbers have the advantage, of course, of being the first to start in their order from each control. The Contest Committee, consisting of F. R. Tate, John H. Phillips and Charles E. Michel, has formally announced the appointment of J. D. Perry Lewis, of the Halsey Automobile Co., as referee. Checkers at controls will be Samuel Breadon, of the Western Automobile Company; Charles E. Michel, of the Union Electric Company; and Harry W. Blodgett, the association's attorney. The Technical Committee, as decided upon, is: George P. Dorris, of the Dorris Motor Car Company; A. R. Walton, of the Standard Six factory, and Stewart McDonald, of the Moon Motor Car Company. Two trophies are offered, the principal one being the St. Louis *Star* cup for touring cars, and the other a handsome cup for roadsters, donated by the association. The entry fee is $25, but $20 will be returned to those whose cars reach the first control. The Buick "Old Red Wing," the pathfinder, will act as pilot.

The Board of Police Commissioners has purchased a Ford touring car for Chief of Police Young. The Chief and Hobart Brinsmade, purchasing agent for the board, tried the car out before it was accepted, and found it satisfactory. The car is in extreme contrast to the runabout the St. Louis chief formerly was provided with. Chief Young makes a tour of every district in the city two or three times a week, and a good, substantial car was found necessary.

The Auto Transit Company of St. Louis has been formed, with J. J. Quinn the moving spirit. The company will incorporate for $25,000, the papers having already been prepared. Mr. Quinn announces that he will start a 5-cent fare automobile line from the city limits to Bailas Road, a distance of 2 1-2 miles. The new line is designed to carry passengers to the new suburban residence division of Winchester Park, and will be the first of its kind established in Missouri. The new district was isolated, as it is 2 1-2 miles from the nearest car line from the city. The automobile line, it is declared, will be a great aid to the real estate business in that section. The line will be conductorless, the Van Note tabulators and registers being substituted. Passengers will enter at the rear of the cars and alight from the front. The Van Note tabulators act in the manner of turnstiles, and are much in use on suburban car lines in many parts of the country.

The incorporators of the company are to be: J. J. Quinn, H. L. Van Note, W. D. Helman, and William A. Estep. Mr. Quinn announces that two light cars, each to carry five passengers, will be installed at once, and that subsequently other cars will be added as the demand grows.

Many local motorists attended the housewarming given by the Overland Motor Car Company of St. Louis, which has just incorporated and moved into its new quarters at 3907-9-11 Olive street. The incorporators of the St. Louis Overland Company are Jerome Harrington, T. B. Funk, Howard Harrington, W. M. Armour and C. S. Dines.

The University Automobile Company of St. Louis has been installed in its new garage at 5800-2-4 Delmar boulevard. The building is new and affords room for the garaging of 100 cars. The company will handle the Henry car in St. Louis territory.

The agency for the Van Dyke light delivery automobile has been placed with Kardell Brothers for St. Louis and St. Louis territory. Kardell Brothers handle also the Reo and the Fal.

The Lindell Motor Car Company of St. Louis has moved its salesrooms into new quarters at 4829 Delmar boulevard.

Hoosier Happenings from a Motor Viewpoint

SOUTH BEND, IND., June 13—Work has commenced on the erection of a one-story building on East Washington street, Goshen, Ind., which when completed will be used as a garage by J. E. Smith, agent for the Ford. The new building will be of brick and cement block and well equipped.

Representatives of fourteen northern Indiana counties met in the Federal building and organized an association which will take steps to have State and national legislation in behalf of good roads in this section of the State. Only recently have a large number of the tradesmen, manufacturers and laboring classes realized that good roads in this section will be of as much benefit to them as to the farmers, and the organization is the result of the interest taken by the public in general in the good roads convention recently held in this city at the Oliver Hotel. It was decided to take the matter of good roads legislation up with the nominees to be elected to the Legislature this fall and appoint a committee to draft a measure to be presented at the next session. Articles of incorporation were adopted by the association, which will be known as the Northern Indiana Good Roads Association. The association is expected to accept the offer of Carl G. Fisher, president of the Indianapolis Speedway, who, in a recent visit to the city, expressed his willingness to furnish $10,000 worth of crushed stone for the improvement of the highway between South Bend and Plymouth, Ind.

Marking Route for Kansas City Star Tour

LA JUNTA, COL., June 12—The pathfinding party of the Kansas City *Star* trophies tour arrived at La Junta at six o'clock to-night in the big six Stevens-Duryea, driven by M. C. Nolan, the Kansas City distributor. The route layers traveled over 221 miles at a 26-mile clip to-day, starting at 9:30 at Dodge City, Kan., stopping an hour and a half at noon for luncheon at Syracuse, Kan., a half hour in Lamar, Col., to allow a long funeral procession to pass and many times through the morning and afternoon for photographs.

The route, which is following the historic old Santa Fé trail from its origin in Kansas City to the Western terminus at Santa Fé, N. M., was accurately marked along the highway of '49 most of the time to-day. Besides the granite trail markers erected by the States of Kansas and Colorado and State historical societies, the pathfinding party came across grassy mounds that mark the ruts of the wheels of prairie schooners and the tread of the oxen. At one place the trail expanded to a width of 200 feet in which there were knee-deep tracks of the old freighters.

The party has had an almost unbroken relay of pilots since leaving Kansas City June 9, and many times has been escorted by dozens of cars. The projected route of the tour in all is 2,200 miles, which, so far, has been laid through Emporia, Hutchinson, Great Bend, Dodge City, Garden City, Kan.; Lamar, Las Animas and La Junta, Col.

One Clean Score in Carolina Endurance Run

RICHMOND, VA., June 13—The Carolina Endurance Run, promoted by the *Times-Despatch*, was one of the most splendid successes that the sport has known in this portion of the South. Ten cars, out of fourteen starters, finished the 409-mile trip in good shape, despite the fact that the last day's run was made through a rainstorm that not only drenched the drivers to the skin, but made the roads, in some places practically impassable. Although there were twenty-five cars entered in the run, only fourteen reported for the start on Tuesday morning, the remainder having been withdrawn for various good reasons, principal among which was that the garages, some of which had one or more cars entered, were forced to scratch their entries through the fact that every car in stock had been sold out.

One of the big features of the four-day trip was the hospitality shown the entrants by the people of Virginia and North Carolina at every checking point. It was a gay whirl of receptions, feasts, barbecues and every other sort of the best of good times, at every stop along the entire route, with the last point always making a strong bid to outdo the preceding one.

To one thing was the attention of the party particularly drawn—the superiority of the North Carolina roads over those of Virginia. With a few exceptions—a few miles out of South Hill and Lawrenceville—the Virginia roads were found to be indescribably bad. In many places mudholes two feet deep were encountered, through which it was necessary for the drivers to work their machines with rare care and judgment, to prevent serious accident, while in others huge boulders, that had been lying in the same identical spot since the first Indian trespassed upon the property of the pre-historic race, were encountered, and around which it would have puzzled a snake to have found its way. However, inconceivable as it may seem, the cars wended their way safely over these stretches, though it is puzzling even yet to the drivers just how they did it.

North Carolina is far more progressive in her roadbuilding than is Virginia, for Virginia has no roads that can compare with those in Franklin and Durham counties, North Carolina. The people down in Carolina believe in good roads with all their souls and both State and county make annual appropriations for their betterment and upkeep, an example which Virginia may well follow.

The White Special, owned by B. A. Blenner, which went over an embankment near Littleton on Tuesday afternoon, was dug out of the railroad cut into which it was precipitated and hoisted onto a freight car, arriving in Richmond Friday evening. Here, to the surprise of all who saw the feat, the car was cranked up and ran to the garage on her own power, without a hitch.

Following is the summary:

No. Car	Entrant	Score
	DIVISION 1	
15—Maxwell	Dr. Saml. McAnnally	123
23—Hupmobile	Richmond Motor Co.	243
	DIVISION 3	
10—Chalmers "30"	E. C. Pelouze	35
12—Chalmers "30"	J. T. Palmatory	196
5—Regal	S. Stagg	Disqualified
16—Maxwell	....	Disqualified
	DIVISION 4	
9—Buick 17	Foster Motor Car Co.	0
6—Rambler 53	E. J. Allen	43
13—Buick 17	R. Williams	98
18—Buick 17	J. R. Williams	224
4—Buick 17	T. E. Williams	No final exam.
3—White	B. A. Blenner	Disqualified
	DIVISION 5	
24—Speedwell	Jno. B. Alsop	20

Fuel System of Stearns Model 30-60

(*Continued from page* 1094)

main supply tank as long as pressure is indicated on the gauge.

If the pressure on the gauge G is not sufficient to raise gasoline out of the main tank, and fill the auxiliary tank A, it is a sign that the automatic valve V is out of adjustment; it should be so adjusted that it will admit gas from the cylinder of the motor until the gauge G shows sufficient pressure to afford a satisfactory supply of gasoline to run on. In adjusting the automatic valve V the proper way to go about it is to turn the adjusting screw on the top of the valve marked C2 one way or the other until the gauge registers the desired pressure; if the motor is shut down manipulate the pump P and note when the valve V shuts off the supply of air to the fuel system. It will make a slight hissing noise at the instant of closing.

It will be understood that the float chamber of the auxiliary gasoline tank must be open to the atmosphere or else gasoline will not freely flow under the force of gravity down to the carbureter.

There is one more extremely important point reserved to the last in this discussion, because it is the first thing to look for when trouble is encountered. By taking the mahogany cover off the auxiliary tank A, the knurled cap on the tank will intercept the eye. If this is screwed out a gauze filter will come with it. If the filter is scummed over it should be cleaned, but in screwing the filter back, unless it is fetched up tight, it will leak air. This leak must be stopped or the pressure on the gauge will die, and the gasoline will not be raised up to the auxiliary tank, so that there will be no supply available to the carbureter, and the motor will shut down for want of fuel. There may be a leak at some other point, as at any one of the joints in the piping system, considering any part of the piping between the auxiliary tank A and the main supply tank. The remaining and most likely place to find a leak will be at the filler cap of the main supply tank. The tool kit holds a special wrench which must be used in tightening up this filler cap; it will have to be perfectly air-tight or it will be impossible to go anywhere with the automobile. Pressure on the gasoline system is one of the conditions which cannot be disregarded if the automobile is to run with any degree of satisfaction, but if the leaks cannot be stopped it will then be necessary to work the pump P hard enough to maintain pressure, despite leaks, and in this way, it will be possible to run the automobile long enough to get home, or to a place of repair, where a bad leak may be stopped up. Finally, it is well not to become superstitious if trouble seems mysterious in character:

Aero Show Planned at St. Louis

Under the auspices of the Aero Club of St. Louis, the St. Louis National Aero Show has been organized, and will be held in the Coliseum Building, October 8 to 13, during the period when outdoor aeroplane and balloon events of international importance will take place in St. Louis.

Boston Children Given Outing

BOSTON, June 13—In a column, consisting of 218 automobiles, over 1,000 blind, crippled or orphaned children were given a fine outing on June 8 at Lake Massapoag. The affair was conducted by the Boston Automobile Dealers' Association and proved to be a success from every viewpoint.

Wheels of Progress Hum Busily in Detroit

DETROIT, MICH., June 13—Of the four or five new corporations identified with motoring here, one, the Detroit Monoplane Company, has capital stock of $20,000 paid in. with Fred Weinburg, 118 Alfred street, as the prime mover in the enterprise. Associated with him are his brother, Curt Weinburg, Ray Wilcox, William Anderson, and Alfred Brown. Several well-known members of the Aero Club of Michigan are said to have placed orders with the firm for planes.

The others are: the Shock Absorber Company, to manufacture a patented shock absorber; capital, $5,000; the Detroit Airless Tire & Rubber Company, the reorganized Dayton Airless Tire Company, which is moving to Detroit, has filed notice of its incorporation; capital, $1,500,000. Another event of the week in this line was the increase by the Demot Car Company, the present stockholders subscribing to an additional issue of $25,000 for factory alterations.

The Hale Motor & Machine Company, paid in capital, $125,000, has been incorporated by Charles Ritter, J. C. Hudson, L. J. Brennan, J. E. Dubois, and R. J. Brennan as trustees, all of Detroit, and S. E. Hale, of Cleveland.

Several other new companies are forming, but the details of these are not yet available. Among these are the Bailey Motor Car Company, to build delivery wagons and light trucks; the Johnson Roller Bearing Company, to make a new and different type of roller bearing; the Reynolds Motor Company, to build a new engine with rotary valves and other features; the Hastings Motor Car Company, to build a six-cylinder pleasure car with rotary valves; a new automobile bank; and several agency and selling companies.

It was announced that the W. A. Paterson Automobile Company, of Flint, Mich., an old established carriage firm which has just entered the automobile business and is building the Paterson "30," would establish in Windsor, Ont.

The past week also saw the tripling of the capitalization of three of the General Motors component companies in this State, these being the Marquette Motor Company, Saginaw, from $300,000 to $800,000; the Oakland Motor Car Company, Pontiac, from $200,000 to $800,000; and the Cartercar Company, Pontiac, from $350,000 to $650,000. The original total was $850,000 and the changes raise this to $2,250,000.

Great interest is being displayed here just now in the motor truck end of the industry, and a number of companies are forming to take up this work. The Oliver Motor Car Company is occupying for the present a building at the corner of Grand River and Harrison avenues, with about 5,000 square feet of floor space. This will only be used for the construction of the first few model or demonstrating wagons. Plans are being worked upon for a very large factory building, 300 feet long by 60 feet wide, four stories high for a depth of 90 feet, the balance being but two stories high. The whole will afford a total of 47,000 feet of floor space.

The first Oliver commercials will be of the light delivery type, although a one-ton truck is promised later. This first product will have a carrying capacity of 1,000 lbs., will be powered with a two-cylinder horizontal opposed engine of 4 1-2 in. bore and 4 1-2 in. stroke, a two-speed planetary transmission, made a unit with the engine, the whole forming a unit power plant which will be removable as a whole without removing anything else. The engine will be set down on a sub-frame, but will not be so low but that a bonnet will be used in front. Semi-elliptic springs will be used both front and rear, while the frame will be of pressed steel of channel section, smooth side out. The wheelbase will be 102 in., while the tread is standard. Wheels are large, and equipped with solid tires, 38 by 2 1-2 in. both front and rear. Final drive is by shaft. The very large honeycomb radiator is set in front under the bonnet.

For the coming year, a total output of between 300 and 500 is planned. The price of the wagons is doubtful as yet, but will be in the neighborhood of $1,400, fully equipped. Express bodies will be standard, but any form will be furnished on call.

The officers of the concern are: Lewis Schinnel, president; Paul Wagner, vice-president; Robert S. Hartenseine, treasurer; Frank A. Gies, secretary; and Charles F. Case, general manager.

When the buildings at present projected for the Reliance Motor Truck Company, of Owosso, Mich., have been completed, they will comprise the largest motor truck plant in the world. Announcement was made recently that the General Motors Company will at once commence work upon a number of additions to the present plant. These additions include a large assembly building, a body shop, a large paint shop, and a power plant, the whole of which will occupy 20 acres of ground. Machinery to the value of $150,000 has already been ordered. The plant has easy access to three large trunk railroads, giving unsurpassed shipping facilities.

Michigan Aero Club Plans Many Flights

DETROIT, June 13—Although the officers of the Michigan Aero Club, whose headquarters are in Detroit, have denied that they are planning to offer a prize for a Detroit-Toledo flight, several balloon flights are planned for the summer, and much other general activity in an aeronautical line.

Mexican Trip's First Stage Finished

DETROIT, June 15—Covered with Canadian mud, the Flanders "20" which is making a trip from Quebec to Mexico City ran into this city yesterday afternoon. The car was escorted around town by one day's factory output of Flanders cars, about 40 in all, and twice as many more privately owned Flanders cars. This morning it started for Toledo, Indianapolis and St. Louis. The car left Quebec June 6 and has been on the road nine days.

Speedwell Protest Checks Award

RICHMOND, VA., June 14—Because of the protest of John B. Alsop and Howard Wagner, of the Speedwell Motor Car Company, the award of the prizes in the *Times Dispatch* North Carolina Endurance Run will be postponed until the decision of the referee or the Contest Board is announced. The committee penalized the Speedwell one point each for two motor stops and eighteen points for being eighteen minutes late at Lawrenceville.

Fast Time at Kansas City Meet

KANSAS CITY, June 11—After several postponements the track meet at Elm Ridge was run this afternoon. Fifty thousand people saw Oldfield fail to beat the world's circular track record. The Knox won a five-mile free-for-all in which a Jackson and a Warren Detroit were placed. Time, 6:02 1-5. In the fifty-mile free-for-all the Knox won in 56:07, with a Cutting second in 59:04. Another Cutting was third in 60:04. The five-mile free-for-all handicap was won by Therman in an Auburn with a handicap of 70 seconds. Clark in a Cutting was second and Miller in a Warren-Detroit third. Winner's time was 5:48 2-5.

Maryland to Make Auto Treaties

BALTIMORE, June 13—Governor Crothers is preparing to establish reciprocal relations with Delaware and Pennsylvania by July 1. This will be the initial move to bring about such relations with every State in the Union.

Big Meeting for S.A.E. at Detroit in July

Divers Subjects Proposed for Discussion

HOWARD E. COFFIN, president of the Society of Automobile Engineers, has announced that the meetings of the society to be held at its convention in Detroit, July 28, 29, and 30, will be the largest ever attended by automobile engineers. There will be several professional sessions and that matters of the greatest interest will be presented and discussed by authorities is shown by the following list of proposed subjects, the most important of which will be taken up as fully as time will permit:

It will be a convention of designers and Detroit will have an opportunity to entertain all the chief engineers of the principal makers of automobiles in America, with a good contingent from abroad. The subjects to be discussed are: Gears; Commercial Cars; Electric Vehicles; Gasoline Motors; Materials and Treatment of Materials; Wheels, Rims, and Tires; Ignition; Ball, Roller, and Plain Bearings; Right and Left Hand Driving; Final Drive; Factory Systems; Contests; Miscellaneous Subjects.

The Society of Automobile Engineers. Its future intentions, and the benefits to be derived by its members.
Lines along which the work of the S. A. E. may be made of the greatest benefit to its members individually and to the motor car industry.
Specification and treatment of automobile materials generally.
Standard gauge, sizes, and chemical composition of sheet metals.
Standard sizes of seamless steel tubing.
Standard dies.
Standardization of square holes and keyways used in automobile construction.
Standardization of control mechanism—position of speed notches and actuation of planetary gear pedals.
Standardization of wheels and tires for commerical vehicles.
Nomenclature of motor car parts.
Responsibility of the motor car engineer as to safety of the car designed. Mechanical efficiency of spur and bevel gears. Form of tooth for quiet gears, both spur and bevel. Grinding methods for making quiet gears. Stub tooth and hot-rolled gears. Form of gear teeth for rear-axle bevel gears.
Design of pinions.

Types of Commercial Vehicles and Design Features

Mixed (gasoline-electric) systems.
Comparative merits of having a motor truck engine under a hood or under the seat (both vertical engines).
Proper power and speed of motors and trucks.
Does a transmission on a motor truck need to be heavier than on a touring car, using a motor of the same power?
Chain final drive for trucks and the importance of housing same.
How can the spark and throttle of commercial vehicles best be made fool-proof?
Is a chain-driven commercial vehicle as efficient with the differential separated from the transmission, and should there be more than one universal joint between, where the shaft does not exceed 36 inches in length?
Sliding gear transmissions for trucks.

The Electric Vehicle and Battery Problems

The Edison battery from actual tests; life from practical experience.
Low voltage motors for electric vehicle propulsion.
Recent improvements in electric storage batteries for both power and lighting.
Ampere-hour meters for electrics.
Relation of tire, battery and general repair maintenance cost.

About Gasoline Motors and Auxiliaries

Reports of motor tests.
Motor noises,
Cam shapes and valve operating mechanism.
Die-cast versus sand-cast bearings.
Carbureters.
What is the most quiet carbureter?
Helical timing gears.
Slide, piston and rotary versus poppet valves for gas engines.
Single—versus dual—versus en-bloc cylinder construction and advantages of each.
Three—versus five—versus two-bearing crankshaft construction.
Effect of T-head motor construction on fuel consumption.
Is the valve-in-the-head motor a more difficult one for the novice to operate?
Valve seat angles.
Cast-iron valves.
Power required to drive a motor car on various road surfaces at various speeds.
Foreign matter in commercial gasoline.
Ill-smelling and unsightly exhausts.
Two-cycle motors.
Determination of proper proportioning of cooling systems.
Air cooling.
Valve settings for racing cars.
Motor lubrication; constant level versus mechanical oiler with separate leads.
Chemical decarbonizers, are they safe and effective?
Clearance and limits for pistons, wrist-pins and valve lifters.
Advantages of a six-cylinder over a four-cylinder motor of equal rating.
Thermal and mechanical efficiency of motors for constant horsepower and variable number of cylinders, with special reference to gasoline economy of a six-cylinder motor and single cylinder motors for given kilogrammetric performance.

Automobile Materials and Treatment Demanded

The adoption of uniform symbols for the designation of heat and other treatments in connection with the specification of raw materials.
Hardening carbon steel and alloy steel gears.
Brake materials.
Best steel for ball races.
Casehardening camshafts and like pieces.
Proper materials for transmission gears and shafts for commercial vehicles.
The pyrometer: Its development and use.
The use of the Scleroscope for determining the hardness of metals.

Characteristics of Wheels, Rims, Tires, Etc.

Data on efficiency of pneumatic tires.
Clincher versus quick detachable tires.
Demountable rims.
Advisability or inadvisability of tire lugs.
Power consumption of tires versus their life.
Methods and appliances for carrying spare tires, rims and tools.
Wheel alignment, camber and foregather.

Magnetos, Spark Coils and Ignition Problems

Fixed ignition timing.
Dual versus double ignition systems.

High-tension versus low-tension magneto ignition systems.
Magneto efficiency.
Does the usual magneto arrangement give enough range of spark advance?
Direct or indirect causes of ignition knocks or chirping in large motors.

Ball Roller and Plain Bearings

Ball bearings versus roller bearings.
Live rear-axle bearings—on pinion, on differential, on axle; thrust bearings, from fiber and steel to annular and annular and thrust.
Advisability of providing universal joints with hall bearings.
The variation of current practice in anti-friction bearings. (Paper by D. F. Graham.)

Driver's Seat on Left Hand or Right Hand

Left-hand versus right-hand steering—operating levers in center.
Should the driver be on the left in those countries where the rule of the road is to keep to the right?
Chain versus shaft drive.
Worm drive.
Modern factory construction and its mechanical equipment.
Labor-saving schemes and devices in motor car production.
Shop progress.
Cork insert pulleys.
The engineer and the motor car contest. The lessons of the motor car contest.
Charts for racing drivers to fill in in making reports.
Automobile racing on a more scientific basis.
Leaf springs, their method of mounting and their proper treatment at the factory and in the hands of the customer.
Gradient of curves on roads.
Test data on frame sections.
Most suitable form of coupling between motor and motor-testing apparatus.
Transmission and rear axle noises.
Metal stampings.
Proper gear ratios in three- and four-speed transmissions.
Sheet metals.
Lubrication and lubricating devices (aside from motor) insuring proper lubrication.
Torpedo bodies.
Electric lighting.
Universal joints.
Best method of fastening universal joint sleeves.

Warner Turns His Attention to Aeroplanes

Beloit, Wis., June 13—Announcement was made to-day by colleagues of A. P. Warner, the aeroplane enthusiast, that the latter is planning in secret a unique new style of aeroplane different from any ever built before.

Mr. Warner has just disposed of his Herring-Curtiss aeroplane, in which he made numerous daring trips over Beloit, to Joseph Seymour, the racing driver. It is said Mr. Warner has hit upon numerous ideas of tremendous importance to aerial navigation, and these, with such points of advantage as were presented by his flights in the Herring-Curtiss machine, will be embodied in the new aeroplane. Among one of the aeroplane hobbies of Mr. Warner is one of knowing the exact speed of the machine at all times during flights and his invention of the aero-meter supplied that want, the aero-meter now being used on the aeroplane which Glenn Curtiss himself drives.

The shape of the new aeroplane which Mr. Warner is to build it is said is entirely different from any of those now being used and according to those who are close to the aerial navigator many other vital points which lend stability to the air craft are to be taken care of in a manner more efficient than in other aerial flyers.

Upon several occasions last Fall, Mr. Warner startled Beloit and surrounding country by daring flights in his Herring-Curtiss aeroplane, and the news that he is building in secret a new aerial craft on wonderfully unique plans of his own created a stir in this city.

Aiding Mr. Warner in his aeroplane building are experts who are employed in his factories in all phases of delicate mechanical work. With their assistance and with the efforts lent by men of science of Mr. Warner's acquaintance it is expected that the flights of the new model will surprise even those in closest touch with the world's new sport of aeronautics.

New Hampshire's Brilliant Good Roads Outlook

Concord, N. H., June 13—Judge W. B. Fellows, state auditor, announced to-day that so well had James E. French, chairman of the committee of appropriations, handled the finances this year, that it will be possible to complete the three big trunk highways without issuing the $200,000 worth of bonds that remained unissued to finance that project. These highways reach out from the mountains to the State borders, touching Massachusetts, Maine and the ocean, covering several hundred miles.

Jottings From Across Big Muddy

Omaha, Neb., June 13—The Maxwell-Briscoe branch in Omaha has moved into its new garage and salesroom at 2115 Farnam street. The new structure is probably the largest and one of the finest automobile buildings thus far completed in the city. It is two stories high, with 50 foot frontage on Farnam street, and is 128 feet deep.

The salesroom is 50 by 40 feet, with large show windows. The finishing is of maple throughout. Back of this is a room for demonstrators, a car of each model being kept there for that purpose. Also on the first floor is a stockroom for accessories and repair parts, 20 by 70 feet. On the second floor is a repair shop and stockroom. The washroom and storage-room are in the basement.

The *World-Herald* endurance run, which was the big auto event of last year in this part of the country, will be a feature of this season again, the *World-Herald* having offered another cup this year.

The South Omaha Automobile Company has opened a new garage at 436-40 North 25th street, South Omaha. Henry Petersen and his son, N. H. Petersen, are the proprietors. They will handle the Cartercar, Deal and Imperial cars.

The work of wrecking the building at 12th and Farnam streets, Omaha, to prepare for the big new garage of the Freeland Brothers-Ashley Company, is under way. The building will be four stories in height, and the Freeland Brothers-Ashley Company and the Apperson Sales agency will occupy practically all the space.

Omaha autoists are pushing a movement in favor of an auto show at the Nebraska state fair this year, and hope to have a building set apart for the exhibition of motor cars. It is believed that the idea will meet with favor owing to the growing popularity of the automobile among the farmers and rural residents.

Taxicab Company Is Common Carrier

Lansing, Mich., June 13—In a decision recently handed down by Attorney-General Bird a taxicab is held to be a common carrier, and as such all taxicab companies will have to make application to the State Railroad Commission for permission to increase or decrease their capitalization. This decision was the result of an application by the Detroit Taxicab Company to increase its capital stock from $5,000 to $100,000.

What's Doing Along Detroit's Automobile Row

DETROIT'S "Automobile Row"—as the selling agencies of cities are usually called—may be said to be in two parts, extending in two decidedly different directions. Thus, there is the Woodward avenue portion, extending northward from the center of the city, this being the principal thoroughfare of the city. Then, there is Jefferson avenue, which also extends outward from the center of the city, but in an easterly direction. This, too, is one of the principal streets. For the present, the buildings, agencies, and men along the former will be described, leaving the latter to some later date, the same applying to such agencies and salesrooms as are located on side streets.

Going out Woodward avenue, the first agency is that of the Buick Company, which is located way down town, standing virtually alone just below Campus Martius. This is a retail salesroom, handling the factory output in all branches, and working directly from the factory at Flint, forty-five miles away. Despite the location, far away from the other selling firms, this agency finds business brisk just now, with a decidedly greater call for the baby of the Buick line, Model 10. Much attention is now being paid to the new delivery wagon, this downtown location permitting access to merchants and retailers.

Above this, there is a break in the "Row" for a distance of nearly a mile, which brings one up nearly to the new site of the United States Motor Company, corner of Charlotte and Woodward avenues. This is a very large lot, with an old-fashioned brick building, which is now being torn down to make room for the more modern office building and garage. The present plans include a ground floor salesroom, garage, and agency for the Maxwell-Briscoe-McLeod Company, handling the Maxwell and Columbia cars. Part of the second or higher floors will also be at the service of this firm. The balance of the building will be devoted to the offices of the officers of the Detroit division of the company, just created.

Two blocks below this, on the corner of Sproat street, the Oldsmobile holds forth in a natty little one-story building, with a wide front and a great depth on Sproat street, the back part being the garage portion. The interior of the building, at least in the office part, is finished in weathered oak, which is very attractive. Following out its former lines, the Olds machines, originally Detroit-built, have a strong hold on the town, very many of the big model with the 40-in. wheels being seen on the streets, this being known as the Oldsmobile Limited.

Midway between the two, at the corner of Bagg street, there is a small group of agencies, with another building just going up. From Bagg street, going down, J. P. Schneider has the corner, by far the largest of the buildings. Next below this is the Detroit Motor Sales Company. Following that, the Remy Electric Company, and finally the Montgomery Motor Sales Company, and the Cartercar Company. The new building just below this has not been completed, nor has this place been definitely contracted for by an automobile firm, but it was built to rent as such.

Agencies: Hupmobile, Winton, Chalmers, Buick and Regal

Schneider is one of Detroit's oldest salesmen, being on Jefferson avenue, just east of Woodward, for a number of years, where he handled many of the most prominent American and foreign cars. By a peculiar irony of fate, the building he occupied then is now used by a horse outfitting firm, selling blankets, harness, saddles, etc. Schneider is now handling the Pierce-Arrow, Stevens-Duryea, and Baker Electric, a line of high-grade cars, this being peculiarly appropriate in this neighborhood, for years the home of Detroit's aristocracy. In passing, it might be mentioned that this city seems to have a peculiar leaning for the electric car, their number here being very great, and probably not equaled by any other city. Whether this is due to the fact that a number of electrics are built here or not is hard to determine, but the fact remains that there are many of this type of car upon the streets here.

The Detroit Motor Sales Company handles the Paige-Detroit and the Warren-Detroit, both made in the city, as the names would indicate. The former is a two-cycle car, selling at a low figure, while the latter is of the more usual four-cycle type, but also sells at a moderate price. The Electric Company, of course, sells the well-known Remy magneto, as well as the other ignition specialties of this Indiana firm. Quite an extensive line is handled by the Montgomery Sales Company, including as it does the American and Speedwell, with the cartercar sharing the salesroom. The latter is a friction-driven car, selling at a moderate price, while the other two cars are listed at higher prices,

Goodyear Tires Are Prominent on the Row. They Are Kept Here

the American, in particular, being an expensive car. In this line, the greatest demand seems to be for the Traveler, of which model it seems impossible to keep one in the salesroom floor. The Cartercar, too, is very popular in this city, being built so close by as to be practically a Detroit-made car.

Above this group, the selling houses skip another long distance to Parsons street, at least a half mile. Below this street, on the East side are the Postal-Doherty Auto Company, and the Michigan Motor Sales Company, sharing a large building, of 60 feet frontage and nearly triple that depth. The former is the selling agent for the White, while the latter is the State sales agent for the Oakland and Welch. Each firm has its own showroom, the front of the building being divided squarely in half by the driveway to the garage.

Diagonally across the street, but above Parsons street, are the city salesroom, charging station and garage of the Anderson Electric Company, makers of the Detroit Electric. This building has the same characteristic Detroit automobile sales building shape with two showrooms, one on either side of the wide drive. the remainder of the building being devoted to the working part of the establishment. The building is larger than those just described, being some 75 ft. front and correspondingly deep. The strong hold which the electric car has upon this city, as just spoken of, keeps this place busy at all times, although from a sales point of view, the floor is bare at all times, the cars selling faster than the factory can furnish them.

Above the next street, very properly named Selden, is a large group, consisting of Brush and the Apple Electric Company on the west side, and the agents for the Hupmobile, Stewart speedometer, Stromberg carbureter, Marmon cars, Winton, Chalmers, and Buick, quite a large and representative group, which might be said to be augmented by the Regal agency in the block above, but practically across the street from the last of the row, Buick, because there is no intervening building.

Everitt "30" Dwells in a Well-Equipped Building, as Shown

The Brush agency is, of course, a factory branch, and has in connection a large garage, this being located at the rear, and entered from the side street, Selden, to which it runs, the building being L-shaped. Next above this the Apple Electric Company has a small place, selling the storage batteries, magnetos, and other ignition apparatus, as well as the Aplco electric lighting system.

The Keeler-Hupp Company is the agent for the Hupmobile and shares a Detroit-style building with a sales agency for accessories, which latter has the Stromberg carbureter as well as the Stewart speedometer, both Chicago products. Collins & Co., having just taken on the Marmon state agency, have space in here also. The Winton Motor Carriage Company place is a factory branch and, of course, sells only the one car, the Winton. Although not a branch, the same is true of the Grant Bros. Automobile Company, dealing exclusively in the Chalmers product. Both of these, as well as Buick on the corner, have the typical floor layout referred to as the Detroit style of building.

This, with Regal, previously spoken of, concludes this group and the next is another short jump away, being some three blocks farther north at Garfield street. Below this is a group of one-story buildings, with the Standard Auto Company, selling the Packard, on the corner; C. F. Gilmour, selling the Mitchell, next, and below the latter, the Neal-Kitchel Motor Sales Company. The last named sells the Paterson 30, the Parry, K-R-I-T, and De Tamble, a long line, varying in price from $850 for the last to $1,400 for the first, but all medium-priced cars. The latter and the Empire Tire Company have the ground floor of a two-story building, the upper floor of which is also devoted to automobile products, Empire tires having part of it, and the Detroit Leather Works, making the Knight leather tires and tire protectors, the other parts. This is in one of the finest parts of the city, being just across the street from the Detroit Athletic Club.

Detroit "Electric" Lives in an Up-to-Date Garage

Across Garfield street is one of the newer buildings, built last year, but now fully occupied. This is a two-story building with the whole ground and second floors devoted to accessories, with but one exception, the agents for the Great Western, also selling as a side line the Everitt "30." The corner is occupied by the B. F. Goodrich Company, selling Goodrich tires and mechanical rubber goods, with a large repair department at the back, on Garfield street. The next store houses C. F. Splitdorf. Here are sold the Splitdorf ignition specialties, coils, magnetos, batteries, etc. Going on up, next is a general sales company, selling Sterling tires and Warner autometers. The rest of the ground floor is given over to the interests of Prest-O-Lite tanks, Emil Grossman with his wind shields and other specialties, and Wheeler & Schebler, while on the second floor are located the following, all well-known in the trade: R. E. Dietz & Rushmore Lamp Company; Lazarnick, the photographer; Auto-Automatic Windshield Company; Hubbard Engineering Company, representing Thermoid Rubber Company, Heinze Electric Company and Lumen Bearing Company; Sibley Motor Car Company; Bosch Magneto Company; and the Rubber Company of America, World tires. Just two doors above, close enough to be a part of the same group, is the Pennsylvania Rubber Company, in its recently opened office. The building, called the Edwin S. George Building, is so nearly composed of glass windows with corners and a roof, that it might be called a glass house. The result is very light showrooms, and a pleasant place to work.

Speaking of glass brings to mind at once the next in order going up the row, the new home, not yet completed, of the Everitt "30." It is the farthest down town of this group, which extends downward from Warren street. The corner, extending back on Warren for 250 feet, has not yet been rented, although several automobile firms are looking at it. The same applies to the second store, while the third has been taken by the Harper-Aldrich Auto Company, selling agents for the Demot car. This brings us to the Everitt building, the sales agents being the Security Auto Company. This building will be one of the future models for agents' buildings. The whole two-story height has been made one story clear, with enormous panels of glass from the sidewalk upward at least 16 feet. Above this are several rows of smaller panes of glass, so that the whole front is of glass. To this alone the building does not owe its distinction, the salesroom being notable in other ways. The whole front, as deep as wide, and this is 60 feet, is made one room, panelled in oak, with a dull finish, as high up as 12 ft. The entrance for cars, to the showroom and to the garage in the rear is by the covered drive between the Security and the Harper-Aldridge companies. For the garage this leads straight back, being of unusual width.

Just above Warren, practically across that street from the building just described, is going up another, but very large, automobile building. This measures some 90 feet in width and about 250 in depth. At present but the side walls and center dividing wall are up, but it is said that this has been rented to a firm farther down the street. Grant Bros. are rumored to be the lucky ones.

Again there is a large gap in the row, this one being about a third of a mile to the next-to-last group, which includes not only the older structures, but two new buildings, not yet finished, as well. One of these is the new Detroit home of the Rapid trucks, while the other is as yet untaken. The Rapid place is finished in a California Mission style, with red tile roof, hanging low over the front of the building, which is of dark green brick. The interior will be equally attractive, with its spacious rooms, plenty of light, and handsome mission furniture.

After the new building, going north, one comes first to the home of Vesta Accumulators, a small store, but devoted exclusively to this ignition firm's specialty. Next above that is where the Eclipse gas tanks and Federal tires are sold. This firm does a general tank business, taking orders to fill or refill any kind, make or type of gas tank. The two-story building beyond this is the "hang out" of Reo and Thomas pleasure cars and Grabowsky commercials on one side, and Stearns pleasure cars on the other, the former being sold by the Century Motor Sales Company and the latter by the Palmer Auto Company. Both report a flourishing business, while the garage in the rear is also doing well.

The building next above is another double purpose structure, the Annett Auto Garage being the nominal proprietors, while the two salesrooms in the front, one each side of the entrance to the garage, are occupied respectively by a firm handling the Auburn and Bernhard Helfern & Company, selling the Herreshoff. Up over the Annett garage, Spooner & Wells, photographers, have the whole front of the building.

On the same side of the street, the west, one block farther north, is the factory of the Beyster-Detroit Motor Car Company, manufacturers of the Beyster-Detroit delivery wagon. Although hardly classified among the sales agents, the front of the deep building is given over to local sales, no other agent being employed. This firm builds a light delivery wagon, of which a number have been sold in the city.

Diagonally across the street is the last of the agencies conducted by a private individual for profit, the only other selling agency on the street being the Cadillac in the block above, but this latter is a factory branch. By this, reference is had to W. F. V. Neumann & Company, handling the Rausch & Lang Electric and the Stoddard-Dayton. This building has a very large frontage on Woodward avenue, some 120 feet, and is, in fact, one of the best arranged garages in the city, the front of the building only being devoted to the use of the sales force. The building is but one story in height, but the width, taken with the great depth, gives the whole a very large amount of floor space. Business is reported brisk both in the electrics and the line of Ohio cars.

Last of the buildings on the street devoted to the sales end is the Cadillac branch, previously mentioned. This is on Woodward avenue, just at the railroad crossing, and a little above Amsterdam street. One block back of this, occupying the same position on the street, is the immense Cadillac factory, while just across the railroad to the north is the factory of the Briscoe Manufacturing Company. The Cadillac building is in two parts, the one containing the salesrooms proper, and the other without the glass front and other indispensable parts of a city salesroom being devoted to the garage and car storage, the factory often making use of this in time of car shortage, that is freight cars. This closes the list of Woodward avenue selling houses.

Rain Checks New Jersey Run

The endurance contest of the New Jersey Automobile and Motor Club, which was scheduled to be run off Saturday, June 11, has been postponed until June 18. The start will be from the clubhouse in Park avenue, Newark, at 5 o'clock in the morning.

Winton Officers Hold Conference

CLEVELAND, O., June 13—Winton branch managers, salesmen and other prominent employees of the Winton company from Boston to Seattle spent the week of June 6 in Cleveland. The first two days were devoted to business affairs, including a thorough inspection of the Winton Six, details of which will be made public on July 1. When business had been disposed of the visitors attended ball games, theater parties, various luncheons and dinners, and indulged in athletic sports. Mr. and Mrs. Winton entertained the entire party on Wednesday with a lake ride on Mr. Winton's big steam yacht, "La Belle," at dinner at Roseneath, the Winton home, and with an evening at the theater.

Among those present at the convention were President Alexander Winton, Vice-President Thomas Henderson, Secretary and Treasurer George H. Brown, George W. Miller and A. G. Schaefer, of Seattle; H. L. Owsney, of San Francisco; W. D. Howard, of Los Angeles; F. A. Hinchcliffe, of Boston; Charles M. Brown, of New York; A. E. Maltby and F. W. Stockbridge, of Philadelphia; W. L. Duck, of Baltimore; Earl H. Kiser and S. R. Iams, of Pittsburg; C. M. Brockway, George Arbuckle, F. H. Walley, F. N. Sealand and Frank Robishaw, of Cleveland; Thomas W. Henderson, of Detroit; J. F. Davis, W. A. Stoker and A. J. Roe, of Chicago; Charles S. Calvert, of Indianapolis; J. S. Johnson, of Minneapolis; J. J. Jack, of Denver, and the following from the main office: Sales Manager Churchill, Advertising Manager Mears, Superintendent Waidig, Purchasing Agent Ranney, Parts Manager Smith, Traffic Manager Baughman, Engineer Anderson, James Winton, W. E. Miner, of the accounting department, and W. J. Ward, of the advertising department.

Mr. Winton contemplates building aeroplanes in which he will incorporate ideas of his own. While in Paris, recently, he spent a great deal of time visiting the twenty plants where aeroplanes are made, and was much impressed. He has ordered a Gregorie monoplane. As soon as the machine arrives he will begin the work of familiarizing himself

Winton Sales Force at Mr. Winton's Residence "Roseneath"

with the art of flying. The machine was shipped on May 30. Frank Lahm, father of Lieutenant Lahm was in charge of the construction.

"I have always been interested in aeroplanes," said Mr. Winton recently, "but I never before had time to look into them. I am going now to see what there is in them. I want to keep abreast of the times. I think it would not be right for anyone in this country to build aeroplanes without making some kind of terms with the Wright brothers. If I ever make a long flight it will be in a machine of my own and one that I have built myself." It is expected that Mr. Winton will make rapid headway in this new undertaking of his and much interest is being taken.

Ground Broken for New Lozier Plant

Work on the new million-dollar plant of the Lozier Motor Company at Detroit commenced May 18 and already the concrete foundations upon which the buildings will stand have been put in. The steel construction work will begin in the near future and the whole fabric is expected to be pushed.

Albert Kahn, the originator of the Kahn system of construction, which is now in general use in building the highest class of automobile plants, is in charge. A. Bentley Sons & Company of Toledo are the contractors. J. G. Perrin, superintendent of the Lozier plant, has general supervision of the work.

The buildings, according to preliminary announcements, will be as complete and perfect in every way as the present advanced stage of the structural art will permit. Mr. Kahn is authority for the statement that they will represent the highest type of accomplishment in that line ever undertaken by him. Particular stress is laid upon the sanitary advancement and material comfort of operatives and employes in the plans presented to the company. Plenty of light and air and the best type of machine room construction will be the chief features of the new plant.

From Left to Right: Albert Kahn, Mr. Bentley and J. G. Perrin

The photograph for the accompanying illustration was taken the day ground was broken for the massive foundations of the main building.

Nine Enter for Munsey Tour

WASHINGTON, D. C. June 13—The entry list for the Munsey historic tour was opened this week and the close of the week found nine nominations, as follows: Premier, Premier Motor Manufacturing Company, Indianapolis; Columbia, Columbia Motor Car Company, Hartford, Conn.; Selden; Maxwell, T. A. Lambert, Baltimore, Md.; two Washingtons, Carter Motor Car Corporation, Washington, D. C.; Reading, Middleby Automobile Company, Reading, Pa.; Ford, Charles E. Miller, Washington, D. C.; Elmore, Frank Hardart, Philadelphia, Pa.

The work of pathfinding the route will begin Wednesday, when an E-M-F touring car, with Tom Skeggs at the wheel, will start from Philadelphia. The members of the pathfinding party are Harry Ward and F. J. Byrne, staff correspondents of the Munsey newspapers, and Nathan Lazarnick, photographer.

Hartford Notes on the Automobile

HARTFORD, June 13—An orphans' day run is planned by the Automobile Club of Hartford for the latter part of June. The children of the Blind Institution are to be included in the outing this year. The committee in charge is hustling to make the affair bigger and better than ever before.

Hartford will have its first sight of a real aeroplane July 4, when Charles K. Hamilton plans to fly from New Britain to Hartford and circle the State Capitol.

Virginia Auto Law in Effect

RICHMOND, VA., June 13—The new law governing automobiles, passed by the last Legislature, goes into effect Wednesday. Most of the autoists of the State have secured their new cards, but there are still a number who have not conformed to the law.

Formerly there was only a charge of $2 to obtain a number, which was good during the life of the machine. The speed limit in the country was fifteen miles per hour. Now twenty miles an hour may be traveled, while the following is a schedule of the new fees: Twenty horsepower and less, $5; over twenty and under forty-five horsepower, $10; forty-five horsepower and over, $20; motorcycle, $2; chauffeur, $2.50; dealers' demonstration license, $50. All old numbers stand annulled after Wednesday.

The new law provides that the operator of a machine shall not drive in the corporate limits of any city or town at a rate of speed greater than twelve miles an hour, unless the local ordinance of such city or town shall provide otherwise. Outside the limits of any city or town, a speed of twenty miles an hour is permissible, except going around curves, down sharp declines, or at the intersection of any crossroads, or over the crest of hills, or in passing other vehicles or riders on roadways, when a rate of speed not exceeding eight miles per hour must be observed.

The law provides that when horses are frightened, upon a signal or request from the driver or rider, the chauffeur shall immediately bring his machine and its engine to a full stop and allow ample time for the rider or driver to pass.

Following the usual annual custom, the Richmond Automobile Club proffered its cars for Orphans' Day, and the children were taken for a spin to the country.

Nearly 400 children gathered at Capital Square Park at 3 o'clock. The route was to Lakeside Park, where the youngsters were turned loose for a romp.

A public subscription fund to be used on improvements to the Midlothian highway from Richmond to Falling Creek, a distance of about twelve miles, has been raised by Supervisor Thomas E. Woodfin, amounting to $5,000.

News Notes from Nashville

NASHVILLE, TENN., June 13—Capital stock to the extent of $400,000 has been subscribed and paid in to establish in Nashville the Southern Motor Works, and the plant of the company now located at Jackson, Tenn., with a small capacity, will be moved here, the new factory to have a capacity of 750 to 1,000 cars per year from the beginning, with provision made for expansion. Several of the wealthiest citizens of Nashville are interested in the enterprise. A charter has just been secured, incorporating the company for $400,000. The incorporators are are follows: A. H. Robinson, Exile Burkett, John L. Wisdom, Geo. W. Killebrew, Johnson Bransford, Arthur B. Ransom, G. M. Neely, J. H. Ambrose, John W. Love and John H. Howe.

The company has already secured a building, having purchased the factory of the Phoenix Cotton Mills, and it is now being cleaned and rearranged. Exile Burkett is president of the company, A. H. Robinson is vice-president, J. H. Fisher, secretary and treasurer, and W. H. Collier, superintendent. The company manufactures the Marathon, a car that sells for $1,500.

The Nashville Motor Car Company now has on display in its show rooms a full line of 1910 Buicks, and also a Dorris car and a Dorris chasis. The chassis has been displayed at a number of shows and was loaned the Nashville auto firm. Duncan R. Dorris, the manager, is a brother of the designer.

An automobile highway is to be built between Morristown and Rogersville, Tenn., a distance of 22 miles, arrangements having been completed at a public meeting held for the purpose.

The Hoard-Cregor Company, which recently moved into a new garage on Broadway, held a public reception for several days, lately. The house was attractively decorated for the occasion and models of the various cars represented by the company were on exhibition.

Montauk Light or Bust

Under superb weather conditions and with everything favorable for good sport and a pleasant tour, the "Montauk Light or Bust" run of the Motor Contest Association started from Madison Square Tuesday morning. The cars were classified in seven divisions under Class A rules according to list prices.

The first day's schedule called for a long run down the south shore of Long Island, approximately 211 miles, over 50 miles of which is through the celebrated Montauk badlands. Over the barren lands and close to tide water, the course lay for miles, the ocean dashing against the beach at their feet, and the seabreezes blowing into the faces of the tourists. The return trip was by a more northerly route. A Thomas Flyer, in charge of Raymond Beck, laid the confetti trail.

The other official cars included a Knox, carrying Referee Allen C. Alderman, president of the Long Island Automobile Club; a Mitchell "6", pacemaker, with Oakley Delamater, and a Franklin, Welch-Detroit, Palmer-Singer, Chalmers, Packard, Velie, Babcock and American carried press representatives and working officials.

"Senator" William J. Morgan, president of the Motor Contest Association, authorized the statement that this run would prove the last that he would promote. Senator Morgan has had much success in this line of endeavor and in speaking of his determination said that he figured that he had done enough. The list of entrants is as follows:

Car	Entrant	Driver
Division 1A—$800 and under—		
Hupmobile	F. L. C. Martin Auto Co.	Elmer D. Cutting
Hupmobile	F. L. C. Martin Auto Co.	R. E. Gillam
Division 2A—$801 to $1,200—		
Ford	Ford Motor Co.	W. A. Starbuck
Mitchell	Mitchell Motor Co. Brooklyn Branch	D. M. Hasbrouck
Buick	Buick Motor Co.	E. E. Easter
Ford	Ford Motor Co.	W. B. Young
Division 3A—$1,201 to $1,600—		
Regal	Regal Detroit Auto Co.	
Mitchell	William Simonson	William Simonson
Chalmers	Continental Caoutchouc Co.	E. Miles Welch
E-M-F.	Studebaker Bros. Co.	E. A. Taylor
Division 4A—$1,601 to $2,000—		
Pierce Racine	S. W. Fromm	Lewis Strang
Velie	Garland Auto Co.	
Auburn	LaDue-Carmer Motor Co.	Herbert F. Earl
Mitchell	Mitchell Motor Co. of N. Y.	O. R. Delamater
Elmore	John L. Gwyer	John L. Gwyer
Westcott	Dunlop-Taylor Motor Co.	Thomas Wilson
Buick	Dr. William H. Nafis	Dr. William F. Nafis
Buick	Buick Motor Co.	W. Davenport
Buick	Buick Motor Co.	Philip Hines
Buick	Buick Motor Co.	Frank Remsen
Division 5A—$2,001 to $3,000—		
Haynes	Walter E. Shuttleworth	Walter E. Shuttleworth
Mercer	Mercer Auto Co.	
Franklin	Franklin Auto Co.	C. J. Hickman
Selden	Cloud-Marts Auto Co.	George E. Mack
Division 6A—$3,001 to $4,000—		
Franklin	Franklin Auto Co.	Paul Harvey
Knox	Knox Auto Co.	H. K. Sutherland
Welch Detroit	Welch Detroit	Ward Smith
C. G. V.	C. G. V. Import Co.	Arthur Coombs
Division 7A—$4,000 and over—		
Zust	American Zust Motor Co.	V. P. Pisani
Amplex	S. J. Wise & Co.	Walter Jones
Fiat	Hugo Ricca	Peter Smith
American	American Auto Co.	Earle A. Cryne
Stearns	Edgar Gibbs Murphy.	Edgar Gibbs Murphy

Delawareans and Philadelphians in Accord

WILMINGTON, DEL., June 13—As a result of the persistent and aggressive work of the Delaware Automobile Association, Delaware has been eliminated from the fight between the city of Philadelphia and New Jersey automobilists, which had reached a point where it had become very annoying to Delawareans, particularly residents of this city, who often motor to Philadelphia, chiefly for the purpose of enjoying a ride through Fairmount Park. While the association members are reaping the benefit, so are all other Delaware automobilists, and naturally the association and its officers, who were instrumental in accomplishing this result, are receiving a great deal of praise.

In order to insure enforcement of the Pennsylvania automobile law within the city limits, and incidentally to keep out New Jersey autoists who sought to come in without Pennsylvania licenses, the Department of Public Safety of Philadelphia about two months ago issued an order requiring all cars entering the city without Pennsylvania license tags to be driven to the City Hall, where a permit must be obtained before the machine could proceed further. In the case of Delaware this permit did not cost any money, though it resulted in a great waste of time and also in much annoyance. Delaware and Pennsylvania have reciprocal relations, so far as motor cars are concerned, which enable those bearing the tags of either State to enter the other with a home tag. The reciprocal period in each State is 10 days. As a result, there is the best of feeling between Delaware and Pennsylvania, but just the contrary is the case between Pennsylvania and New Jersey, the latter not being willing to have reciprocal relations, and the result is that a Jersey machine is not allowed to enter Pennsylvania without a Pennsylvania license, if it can be prevented.

This is why the city of Philadelphia issued the order requiring a permit for all non-resident machines, and for the same reason the Fairmount Park Commission, a few weeks ago, made an order requiring all machines entering the park to carry special Fairmount Park license tags, which were obtainable at the City Hall, and at certain times from some of the guard houses in the park. This also caused a great deal of annoyance and confusion to Delawareans who went to the park, for if they depended upon obtaining a license tag there and happened to strike the wrong gate they would be required to leave the park and go around it until they came to a place where the tags could be obtained. As was the case with the city authorities, there was no fight against Delaware, but Delaware had to put up with the annoyance just the same, until the Delaware Automobile Association was able to revolutionize the whole situation.

The trouble came to a climax the early part of last week, when the Department of Public Safety of Philadelphia directed the police to rigidly enforce the order requiring permits, which had not been enforced prior to that time, though it was issued some time ago.

The city and park matters were both taken up by the Delaware Automobile Association, through its executive committee. The association has an attorney in Philadelphia, who was also of assistance. He pointed out to the city authorities that the Pennsylvania automobile law prohibits cities or towns requiring permits in addition to State licenses, and as a result on Friday of last week the order requiring permits in the city was rescinded by the Department of Public Safety, and on the same day the Fairmount Park Commission rescinded its order requiring special tags for the park.

Now all that is necessary for Delaware automobilists visiting Fairmount Park or any place in the city of Philadelphia is to have a Delaware license tag in plain view on the machine, and have the accompanying registration card, to be shown if called for, though the tag is usually accepted without question.

Philadelphia Club Activities

PHILADELPHIA, June 13—The fourth annual summer track meet of the Quaker City Motor Club, at Point Breeze, will be held Saturday, June 18. A feature of the entry blank which is something of a novelty is the announcement of the Contest Committee that if, in their opinion, the number of cars entered in any event is insufficient to guarantee a contest, they reserve the right to return the entrance fees and declare the event off.

The contest fever has attacked even the ultra-conservative Automobile Club, of Philadelphia, and the Tours and Runs Committee of that organization has planned a two-day tour, June 25-26, with a secret-time schedule for each day, to Lake Hopatcong, N. J., and return. Allen Shelden, chairman of the committee, who, by the way, is president of The Motor Company, which handles the Premier car here, and who was the originator of the annual Premier runs, will endeavor to induce officials of large towns on the route to offer prizes for the driver who covers the distance from each day's start to the town mentioned closest to the official secret time. This scheme worked out very well in last Saturday's Premier run. Members only are eligible to compete.

The "sociability" run of the North Wildwood Automobile Club from this city to Wildwood on July 2 next, the preliminary to the club's races on the Speedway there on the 4th, promises to be well patronized. The route will be laid out via Salem and Bridgeton, the automobile club of the first-named city having asked the privilege of furnishing lunch to the contestants. Besides providing much sport, without the hard work inseparable from an endurance run, the cities, towns and villages along the route have been flooded with booklets pointing out the beneficial effects of such contests upon the good roads movement.

Automobile Club in Sage Brush

GOODING, IDAHO, June 13—Motor clubs and alfalfa alike flourish in the sage brush country, and both are seemingly prolific in their growth. The Gooding Motor Club, just organized, has its headquarters where two years ago there was nothing but a lonely ranch house, a railroad siding and an occasional sheep herder to relieve the monotony. To-day Gooding is a city of 2,500 inhabitants, with electric lights, telephones, fifteen miles of cement sidewalk and all the conveniences to be found in cities of ten thousand population in the Eastern States. Motor cars are plentiful in the town, and many of the ranchers use this vehicle instead of horses and wagons.

The Gooding Motor Club starts with a charter membership of twelve, and the motor ranchmen of Lincoln county are sending in their applications, so that the club promises to reach fifty or more before the summer closes. The club has adopted "Good Roads" as its slogan, and it will at once begin a vigorous campaign for the improvement of the roads of Lincoln county. The officers of the club are: President, Judge J. D. Furcht; vice-president, Dr. W. H. Johnson; secretary, Robert W. Spangler.

Delaware Club Run June 18

WILMINGTON, DEL., June 13—The annual run of the Delaware Automobile Association this year will be to Oxford, Pa., and will cover about 82 miles, starting and ending at the Court House in this city and going through London Grove, Pa., on the trip out and through West Grove and West Chester, Pa., on the return trip. June 18 was selected as the date for the run. A sealed time run was decided upon.

In the Realm of the Makers

Paul Gaeth, president of the Gaeth Auto Company, left Cleveland Tuesday, June 7, for a two months' trip in Europe.

The Car-Makers' Selling Company, George L. Derr, president, has been incorporated to do business in New York. The company is located at 1780 Broadway.

The New York Auto Top and Supply Company has opened a branch establishment for the manufacture of automobile tops at Paterson, N. J.; the main branch is at 267 Halsey street, Newark.

The Vickers Auto Car Company, of Coshocton, O., has completed its first car, which will be called the Vickers. The machine is a runabout with a four-cylinder, 2-cycle, air-cooled motor. Carl Vickers, proprietor of the Vickers Repair shop, backed by E. H. McMasters, of Bellaire, O., is at the head of the enterprise.

The New Departure Manufacturing Company, of Bristol, Conn., manufacturers of New Departure ball bearings, is installing a Snow twin-tandem gas engine of 500 horsepower, thereby increasing the power plant to five engines of this type. The new engine will furnish power for three new buildings now in course of erection.

The Sands Specialty Company has been recently organized in Cleveland for the purpose of marketing an improved form of the Sackman starting device. The inventors, W. H. and C. M. Sackman, are both enthusiastic about their product and claim it is the simplest and surest method of eliminating cranking dangers. A factory for the manufacturing of these appliance on an extensive scale is now being arranged for.

The Joseph Dixon Crucible Company at its annual meeting re-elected the old board, consisting of Geo. T. Smith, William Murray, William H. Corbin, Edward L. Young, Geo. E. Long, William H. Bumsted and Harry Dailey. The board of directors re-elected the former officers, namely, Geo. T. Smith, president; William H. Corbin, vice-president; Geo. E. Long, treasurer; Harry Dailey, secretary; J. H. Schermerhorn, assistant treasurer and assistant secretary. William H. Corbin was also re-elected as counsel.

The Canadian New-Way Motor Company, Ltd., a branch of the New-Way Motor Company of Lansing, Mich., has been formed and a plant is to be built at Welland, Ont., a Canadian town a few miles from Buffalo, N. Y. The new company is capitalized at $50,000 and the directors are William E. Newbrough, C. D. Woodbury, E. H. Goodnow, L. M. Gleason and H. E. Thomas of Lansing. Air-cooled gas and gasoline engines will be manufactured and the export trade of the company will be transferred to the Canadian concern, from which exportation can be made to advantage owing to the preferential tariff Canada has with Great Britain and her possessions.

Seventy-five new members have been added to the Portland (Ore.) Automobile Club since the new officers started to work. The slogan is "1000 in 1910," and a recruiting committee is working to raise the membership to the century.

Wisconsin registration June 1 reached 12,740 and applications are coming at the rate of 40 to 60 a day. This is the best motor car year Wisconsin has ever experienced.

Fig. 1—Earl J. Moon in a Moon "30" trying out the beauties of car and road in St. Louis

A new motor car built by the McKeen Motor Company at Omaha, Neb., has just been placed on the LeRoy, N. Y.-Rochester route of the Buffalo, Rochester & Pittsburg Railroad Company. The car is 72 feet long, 10 feet wide and weighs 68,000 pounds.

"Tim" Lynch, well known to Adirondack tourists, has opened a garage at the Leland House, Schroon Lake, N. Y. Mr. Lynch was formerly foreman for Miller Bros., at Glens Falls.

A paper chase has been planned by the Motor Racing Association for its members and guests, June 15. The route has been selected through a remarkably isolated country, but its details will not be given out until the day of the affair. It will be run in the vicinity of New York.

The Minneapolis Automobile Club is constructing a lagoon at its clubhouse at Bloomington, so that members may reach the clubhouse from the city via the Minnesota and Mississippi rivers in launches. The distance by river is 25 miles. Power boat races in the river will be a feature of the late summer, and the club may go in extensively for this branch of sport.

Fig. 2—K-R-I-T car with Baron Von der Noot de Moorsel, who is making a trip around the world. Mayor Breitmeyer, of Detroit, is saying good-by to the Baron

Agency and Garage News

Frank F. Weston has been appointed general sales manager of the Mercer Automobile Company, with headquarters at Trenton, N. J.

W. A. Gilbreath has taken on the management of the Motor Car Sales Company at Indianapolis. The concern handles the Peerless and Everitt "30."

Frank Donnell, for many years connected with the Ford Motor Company, has been appointed assistant manager of the Atlanta branch of the Ford company.

C. H. Bigelow, who at present is making a transcontinental tour in a Mercer car, has experienced some bad weather and heavy roads. He is approaching his destination, Los Angeles, over the old Santa Fé trail.

The Hollenbeck Automobile Company, of Portland, Ore., have secured the agency for the Croxton-Keeton car in that city.

C. A. Eaton has taken the agency for the Westcott car in Boston. He formerly handled the Lambert and is well known in the trade.

The O'Neil Tire & Protector Company has opened a sales depot at 126 Massachusetts avenue, Boston, Mass. F. W. McGahan, formerly of Ennis Tire Company, is manager.

The Haynes Automobile Company has closed a contract with F. H. Grasswick, Calgary, Alberta, Canada, to take the Haynes agency for the territory of Alberta and Western British Columbia.

The Meyer Carriage and Auto Company, 322-324 Ellicott street, Buffalo, is the distributor of the Pullman motor car in Buffalo and vicinity.

Joseph Nelson, of Montpelier, Idaho, and M. Crumrine, of Greenville, Ohio, will handle Great Western cars exclusively, having been recently appointed agents by the makers of these machines.

The Cincinnati branch of the Goodyear Tire & Rubber Company, for some years located at 317 East Fifth Street, will move on or about July 1, to new offices at 127 East Seventh street, the "Automobile Row" of Cincinnati.

The Chisholm Sales Corporation, which was recently incorporated in Buffalo, has opened headquarters at No. 730 Main street in that city. The concern will have the Buffalo agency for the National, Locomobile and Speedwell motor cars.

The Studebaker Automobile Company is seeking a location for its Pittsburgh shop work. Plans for a four-story building are being prepared and a site will be announced shortly. This branch covers the western half of Pennsylvania and parts of West Virginia and Ohio.

The J. Ludwig Co., Inc., of 20 Camfield street, Newark, N. J., is building a three-story fireproof structure at 275-279 Halsey street, that city, which will be ready for occupancy about July 1. The company has the State agency for the Randolph Commercial Wagon and will add a pleasure vehicle to its line in the fall.

The Garage Owners' Association of New York will hold its first annual dinner at Reisenweber's, June 23. A large attendance is expected and a list of notable speakers will take part in the program. The association now includes two-thirds of the garages of Manhattan and the Bronx. At the last meeting five new members were elected and several applications for membership from Brooklyn and out-of-town were received.

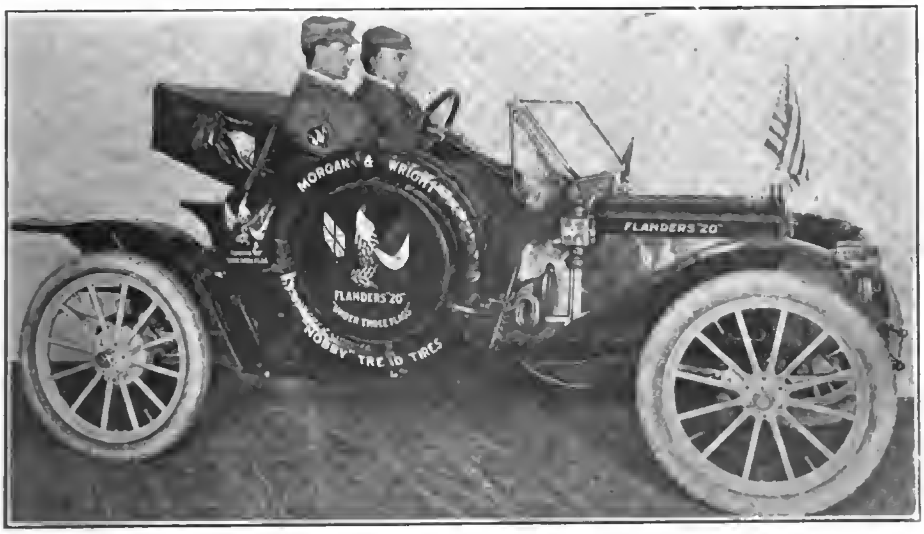

Fig. 3—Flanders 20 "Under Three Flags" ready to start its trip, extending from Quebec to Mexico City

J. P. Dick was recently appointed State agent of the American cars at Atlanta. He has offices at 105 North Pryor street.

A. G. Spalding & Brothers have removed from 200 Halsey street, Newark, N. J., to their new branch at 845 Broad street, that city.

Edward T. Smith, formerly in the sales department of the Iroquois Rubber Company, of Buffalo, has been appointed manager of the company. John S. Watterson is the assistant manager.

The A. R. Mosler Company announces that it has secured the services of H. A. Wattenscheidt, formerly with James L. Gibney & Bro. Mr. Wattenscheidt will cover the New England territory.

C. C. Early, recently manager of the used motor car department of the Franklin Automobile Company, is now connected with the sales department of the Euclid Automobile Company, of Cleveland.

A. W. Woodruff, formerly connected with the Western Reserve Motor Car Company of Cleveland as selling agent for Apperson cars, has joined the Cleveland sales force of the Stearns Company.

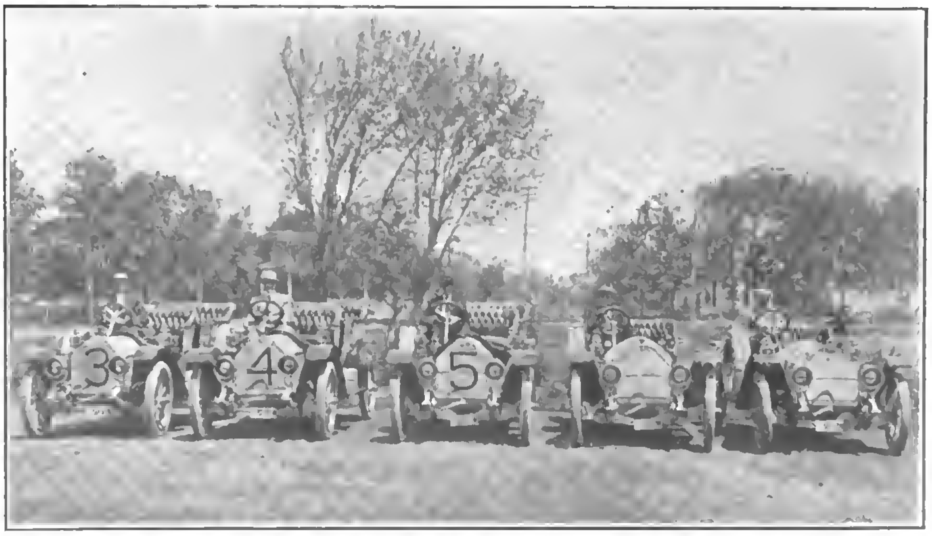

Fig. 4—Battery of Chalmers cars as they will be found in line battling for supremacy in the Glidden Contest

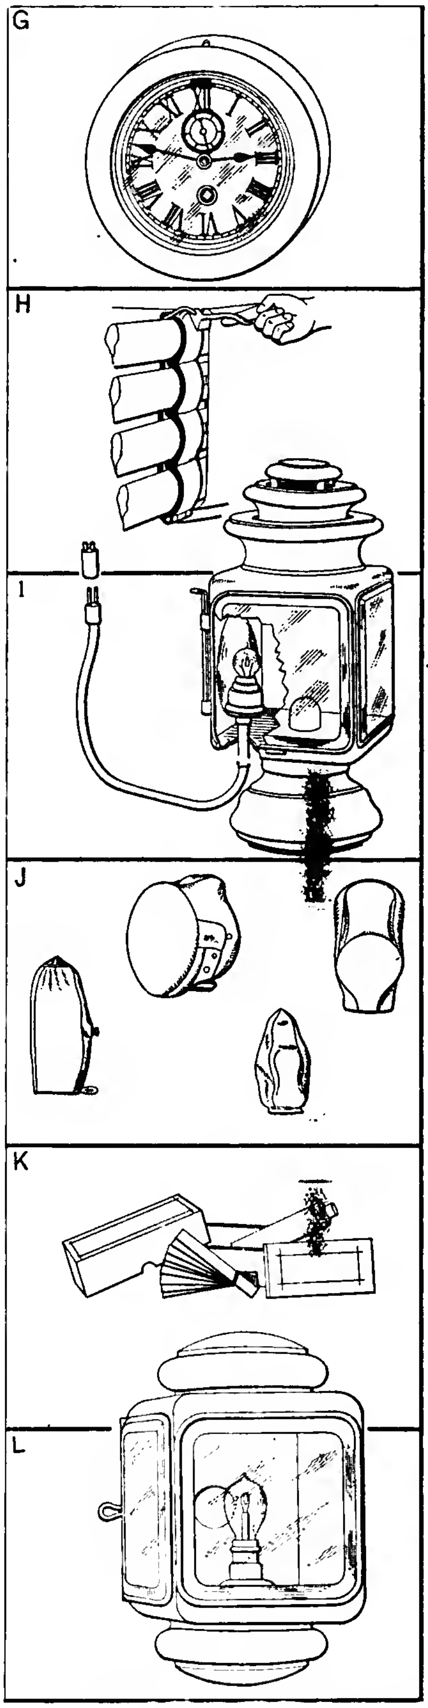
Seen in the Show Window

THE CORRECT "time o' day" is an important element to the automobilist. Watches frequently succumb to the jarrings and moisture inseparable from a long cross-country tour, and a reliable chronometer is therefore a joy forever, even if not a thing of beauty. But the most recent effort of the Chelsea Clock Company, of 16 State street, Boston, Mass., combines utility with attractiveness of appearance. The Chelsea Auto Clock (G) is of the eight-day type, built with a view to stand the jolts and jars of the roughest roads without wavering. It comes in four styles —"Round," "Offset," "Special" and "Limousine," all of which are furnished in 2¾-inch dial diameter, and the first three named in the 3½-inch size. The Chelsea Auto Clock is fitted with the same movement which the company supplies for hard use on locomotives, steam fire engines, etc.

LONG automobile tours without a top to the car are fraught with discomfort and an excess of moisture in many cases, especially if ladies form a portion of the party. But under certain conditions of rough going a top becomes an unmitigated nuisance, what with rattling, broken bows, buckling and numerous other shortcomings. To minimize these troubles the Auto Specialties Mfg. Company, 812 Unity Building, Chicago, has patented the Bair Auto Top Holders (H), a device which will obviate jarring, chafing, jolting, rattling, broken bows and all the minor ills to which the average automobile top is prone, besides doing away with all straps and buckles.

AUXILIARY ignition work, if it is to be relied upon, demands that the battery which is to furnish the electrical energy be of the kind that will remain inactive for even months at a time, and when the critical moment comes it must be ready for instant use. If a storage battery is selected several matters of importance must be considered, among which the question of sulphation is not the least. If a battery is not properly designed and constructed it will self-discharge, and in the process a condition of persistent sulphation will set up, which not only defeats the proper working of the battery at the right time, but it so affects the structure that it will scarcely be worth recharging with a view to future work. In this and many other particulars it was the idea of the Witherbee Igniter Company, Springfield, Mass., to so manufacture its ignition batteries that they will do the very work for which they are intended. A "Witherbee" is here offered as Fig. I; it is a portable six-volt battery of convenient form, which, when it is taken away to be charged, is easy to handle.



G—Chelsea Auto Clock; H—Bair Auto Top Holder; I—Witherbee Igniter; J—Hopewell Lamp Covers; K—Carborundum Compound; L—Castle Electric Lamp.

AUTOMOBILE lamps are a sufficiently expensive accessory to warrant the best of protection for their polished surfaces against the attacks of the weather and the mud and silt of the streets and roads. Careful owners and the manufacturers of access-ries have met on common ground in this particular, with the result that many clumsily fitted lamp covers have been evolved which, while they perform their task of protection in a satisfactory manner, are so crude in appearance that they strike a discordant note in the outfitting of many an otherwise perfectly equipped car. To remedy this defect the Hopewell Brothers, of Newton, Mass., have devised and are marketing a line of Perfect-Fitting Lamp Covers (J) of various sizes, made of the best quality of fleece-lined rubber cloth. The Kinder Tire Covers, in enameled duck are also a product of this firm. They are fastened at the end, and with but five buttons.

IN GRINDING down a worn valve an element of primary importance is the possession of a reliable and ready-at-hand grinding compound—one which will cut very fast and very clean and insure a positively true contact seat. The machinist who relies upon his own skill in producing such a mixture often fails to attain the maximum of efficiency, either too much grease or an excess of carborundum powder marring the accuracy of his work. The Carborundum Valve-Grinding Compound (K), made by the Carborundum Company, of Niagara Falls, relieves the machinist of all worry over the preparation of an efficient grinding material. That company puts up its compound in two collapsible tubes, one containing coarse mixture for rough grinding, the other fine mixture for finishing. A package of carborundum cloth strips for cleaning carbonized matter from contact or vibrator points goes with each outfit.

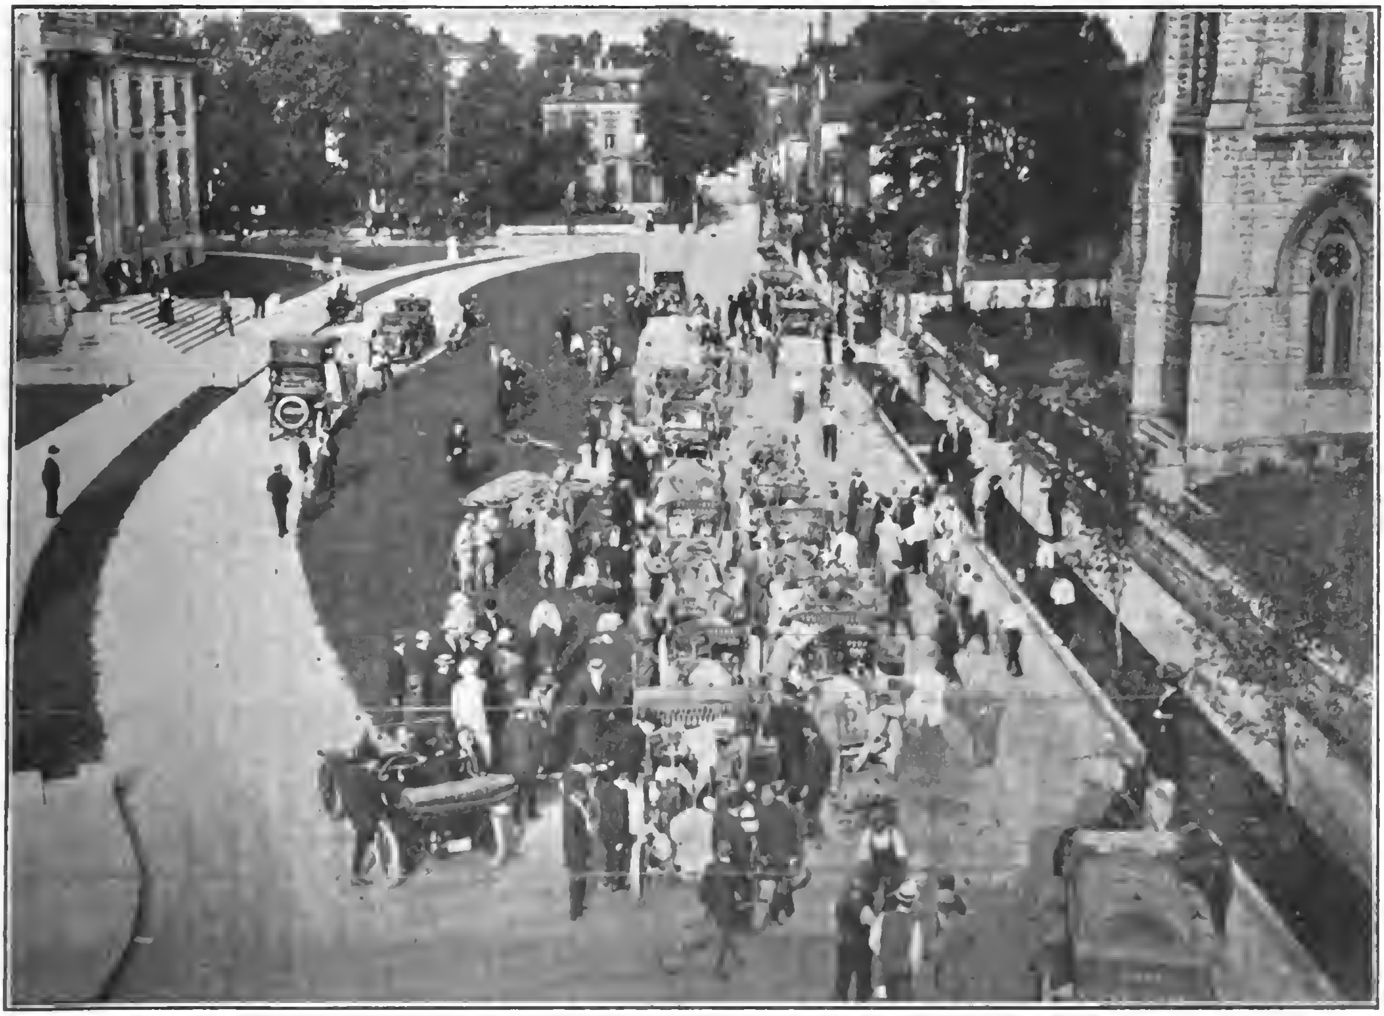
THERE IS something about an electric automobile lamp which appeals to the motorist who desires up-to-the-minute equipment on his high-priced car. There is a market for such a lamp if the danger of short-circuiting be eliminated and the bulb wires so placed as to be easily get-at-able in the event of breakage or needed repairs. Such a lamp has been devised by the Castle Lamp Company, of Amesbury, Mass. It is called the Model 100-E Electric Side Lamp (L), and possesses all the most recent improvements which make for ease and quickness of renewal and repair. The style shown is made of extra-heavy gauge brass, has new-style, extra triple-plated 4¾ x 4¾-inch reflectors of French plate thickness, with a large, red jewel in the rear.

THE AUTOMOBILE

Nine Days of Glidden Besmirched Records

SHEFFIELD, ALA., June 16—To-day's run of 119.7 miles was the shortest in the tour. In crossing the numerous fords several contestants swung rubber aprons over the radiators to prevent water splashing inside, but there was no use for such precautions. This act on the part of many provoked considerable discussion as to whether such was permissible or not and the referee waived all penalties as might have been imposed for such work. In spite of the shortness of the day's run and the comparative ease of the roads, penalties were imposed as follows: Chicago trophy class—No. 100 Moline, 9 points for oiling spring shackles in the noon control. No. 105 Parry, 12 points for fastening up a muffler. No. 108 Cartercar, 2 points for a temporary repair of the clutch pedal, and No. 111 Westcott, 2 points for working on a loose seat.

MEMPHIS, TENN., June 17—Never before in a Glidden tour has there been so strenuous a trip as to-day's 162 miles from Sheffield to Memphis. The route to Corinth, the noon control, 62 miles, offered the worst possible roads imaginable—the merest trails along the sides of hills covered with underbrush or across bog holes in the swamps. Over such an impossible course the cars traveled on 18- and 20-mile-an-hour schedules. As a result eleven contesting cars were late at Corinth, leaving only four that checked in there on time, these four being No. 1 Premier, No. 5 Chalmers, No. 9 Parry and No. 7 Maxwell. The others were late from one hour to over two hours. For over 50 miles the roads were horrible and literally took the heart



HOW THE CONTESTING AUTOMOBILES WERE NESTED AT THE CONTROL AT LOUISVILLE and patience out of the well-nigh exhausted car crews.

Among the Glidden contestants No. 2 Premier received 121 points for late arrival at control and 4 points for adjusting the igniters in its make-and-break system of ignition. No. 3 Chalmers received all told 162 technical penalties for such work as tightening terminals, putting on a new water line gasket, work on the steering gear, using a new spark plug and other minor difficulties. No. 4 Chalmers, driven by Joe Matson, received 89 points for losing his muffler and trying to replace it, and other car work. No. 6 Cole lost 3 points in adjusting brakes. No. 10 Glide had 29 points for lateness. No. 11 Ohio lost 11 points on technical matters and 54 on time. No. 14 Pennsylvania 6 was withdrawn during the day and received its total of 1,000 points for this withdrawal, but previous thereto had been charged with 338 points on technical matters, including as they did work on the muffler, straightening a steering arm, adding a new muffler pipe and performing other minor work. No. 15 Cino was 54 minutes late at the noon control, exclusive of the 3-minute time allowance.

In the Chicago trophy division every car contesting received a penalty for being late and three of them received technical penalties. No. 100 Moline was given 3 points for lateness, but had a clean technical score. No. 101 Moline received 6 points for filling the radiator outside of controls and 44 points for being late. No. 102 Moline was clean technically, but was taxed 39 points for lateness. No. 103 Lexington was given 2 points for tightening a steering arm and 222 for lateness. No. 105 Cole was withdrawn for having burned out a crankshaft bearing caused by the oil pipe breaking when crossing the bottom lands. No. 106 Falcar was clean, but driver Van Sicklen lost 83 points on time. No. 111 Westcott was also clean technically, but received 142 bad marks for lateness.

The Lexington 110 was withdrawn during the day because of breaking a steering arm and not having the necessary spare parts on hand. No. 108 Cartercar was levied against to the extent of 143 points for repairing a clutch pedal, working on distance roads, and repairing the radiator support parts. Its time penalties are not known to date.

Little Rock, Ark., June 18—Although the cars checked out of Memphis this morning at 7 o'clock, it was midnight before many reached the Marion House here to-night, making in all seventeen hours on the road. This was due to two ferries that had to be crossed by all of the tourists, the first being at Helena over the Mississippi, and the second at Clarendon over the White river. In order to get the cars across the river the Helena motorists secured a large lumber barge on which all of the cars were loaded at one time and were then towed across the stream to Helena. In midstream a meeting was called on deck, Chairman Butler issuing final instructions on the *modus operandi* of the checking system at the ferry; but a long delay followed before the cars reached *terra firma* and started on.

The 63 miles from Memphis to Helena were novel in that the route lies for miles along the base of the levee used for preventing the Mississippi overflowing its banks. The going was lumpy, and as a result some of the cars suffered more or less penalization.

A—Cartercar, No. 108, between Louisville and Bowling Green
B—Chalmers-Detroit Car Stuck in the Mud
C—The Cole, No. 104, Checking Out in the Morning
D—Premier, No. 2, Crossing a Ford En Route
E—The Cino Car Making Good Time on the Road

The second stage of to-day's run, from the Mississippi to Clarendon, on the White river, was over a monotonous, flat country used largely in the cultivation of cotton and corn. The road was one of the easiest of the tour so far and the schedule was easily maintained.

At Clarendon the ferry facilities comprised two barges lashed side by side. Instead of simply carrying the cars across the river a ten-mile trip down stream was made and the cars landed in the midst of a forest through which they were run for ten miles to the village of Roe, where they were checked out at 6 o'clock for the 90-mile run to Little Rock.

The roads were straight, with wire fences on either side. The rice fields around Stuttgart were flooded with water that appeared to be some 6 inches deep, and above the surface of the water the heads of the rice plants were seen. Leaving Stuttgart the same flat country was encountered until within twenty-five miles of Little Rock, when rolling territory was invaded. This run was made after sundown by all of the tourists, the acetylene headlights and oil side lamps being seen flickering all over the country as the night slowly moved along. This was the first occasion in a Glidden tour in which a night run has been indulged in, but no difficulty was experienced in following the route.

F—Moline, No. 101, Between Bardstone and Bowling Green
G—Nashville Control—Putting the Cars Under Cover
H—Maxwell, No. 10, Between Louisville and Bowling Green
I—The Falcar, a Prominent Chicago Trophy Contender

Despite the easy going No. 2 Premier, driven by Ballinger, had to solder its gasoline tank, which cost 76 points. Besides this it was 21 minutes late at Clarendon control and lost 3 points for taking on extra gasoline at Helena, giving the total for the day at 118 points.

No. 9 Parry had its muffler almost torn off, and 4 minutes were needed to complete the repair; a fan belt was replaced and 6 more points added for tightening front wheel and tie rod bolts. The total penalty against the Parry was 20 points.

No. 11 had 114 points levied against it, caused by taking off and repairing the radiator, and after doing this once having to do it a second time. Hand in hand with the radiator difficulties was that of taking on water and oil.

In the Chicago trophy field Moline No. 101 lost 14 points for putting water in the radiator three times outside of control, adding oil once and tightening a spark plug.

No. 108 Cartercar received all told 405 points, made up as follows: 393 for replacing a broken spring and the remainder for taking on gasoline, oil and water outside of control. The small Cartercar and Cole No. 6 were withdrawn to-day.

Hot Springs, Ark., June 19—To-day's run of 53 miles from Little Rock here was unique in that it is the first time in which a Sunday was used for a run. The 191-mile trip to Texarkana over rough roads was too severe a one-day test in view of the grueling the cars have already received and it was decided to take the 53-mile run here to-day and at the same time give all hands a chance to use the hot baths.

When the final reckoning was made this afternoon it was found that several cars had received penalties, one of the most serious being No. 103 Lexington, which struck a very soft spot in the road and broke the right side member of the frame just back of the front axle. Driver Moore at once withdrew from the contest, but later to-day reconsidered his course.

The Glidden ranks suffered a couple of penalties to-day, one being No. 15 Cino, which received 16 points for tightening the hub flange bolts in the left rear wheel. No. 8 Cartercar suffered 28 points on work tightening spring clips and 13 more for late arrival. No. 11 Ohio suffered 18 points for taking on water due to a leaky radiator and also 18 points for lateness.

No. 108 Cartercar fell out with a broken rear axle when a little over 10 miles out of Little Rock and the other Cartercar No. 8 in the Glidden was late, due to helping the disabled car out of its dilemma.

Texarkana, Ark., June 20—To-day's run of 138 miles from Hot Springs to here has resulted in eliminating two of the three remaining perfect scores, and to-night there is but one car running with a perfect road score to date and that car is No. 5 Chalmers, driven by W. Bolger. The other perfect scores to pass out of existence to-day were: No. 1 Premier, driven by Ray MacNamara, and No. 7 Maxwell, driven by H. E. Walls. Others penalized were No. 2 Premier, No. 4 Chalmers, No. 8 Cartercar, No. 9 Parry, No. 11 Ohio, No. 15 Cino in the Glidden, and No. 106 Falcar, No. 101 Moline and No. 103 Lexington.

DALLAS, Tex., June 21—To-day's record run of 217 miles found No. 3 Chalmers, No. 4 Chalmers, No. 7 Maxwell, No. 15 Cino, No. 102 Moline, No. 107 Maxwell, No. 106 Falcar among the sufferers. In 1909 five had clean road scores at the finish; this looks like a no-clean-score run.

Distant Verdure Always Looks Greenest

BY MISS CORA A. MOORE

The Automobile Blue Book was utilized during an interesting path-finding trip around New York City in an attempt to show that it is not necessary to go on long tours in order to enjoy the automobile and all that it offers. The Riverdale Avenue route on the road to Yonkers leads to the autoist's best view of the Palisades. Local history (Baedeker feature of the Automobile Blue Book) was studied to good advantage.

THE majority of motorists know their long runs thoroughly enough, but they would be distinctly at a loss were they called upon to designate a round tour from New York which could be accomplished in a day's time at a comparatively easy pace, and yet afford an entrancing diversity of scenery, good accommodations and fair roads.

But there are such journeys, and the autoist may, very near home, with a little stretch of the imagination, fancy himself an intruder amid the glories of the Berkshire or Shinnecock Hills, or even of the matchless Killarney Lakes.

One of these trips whose outline may be useful or inspiring to that one-day-long auto wanderer lies out through Yonkers, either through Broadway or Riverdale avenue to Brewster. Of course, exact roads and turnings, mileages and all that information is given in the Blue Book, and the way is plentifully supplied with direction signs. At an easy rate, with a none too early start, it may be completed with two hours of daylight to spare.

While Yonkers admits that it is not so large as New York, it insists that in point of age the larger city has "nothing on" the smaller. It started its existence during the days of New Amsterdam as the manor of Colendock, the property of Patroon Van der Donck. Yonkers got its name in a strange way. Van der Donck, coming here in 1642, lived in so much fashion that his property came to be called "de jonkheer's landt"—the gentleman's land—from which the translation to Yonkers is easy.

The pride of the town is the very wonderful Colonial relic and heirloom, the Phillipse Manor House, where lived Washington's first love, Mary Phillipse. During the Revolution she was accused of treason and the house confiscated by the Government. Phillipse Manor House is still in good condition and is used by the municipal government of Yonkers as a city hall. It is credited with having been erected in 1682.

The tablet on the monument near Dobbs Ferry tells how the old house still standing there was once the headquarters of General Washington, and a little farther on is the André Monument, that marks the spot of the capture of

An Island Approach to Lake Mahopac

the unfortunate and misled British major with the evidence of treachery concealed in his boot. This strip of country was the theater of much Revolutionary history. War swirled through Westchester in those days and it was in the Livingston mansion that Washington met Rochambeau in 1781 and planned the campaign of Yorktown. In May, 1783, under this same roof, the papers were signed by which England renounced all claims to America.

Between Dobbs Ferry and Tarrytown are some of the most magnificent private estates in the country.

A Spot for Fishing Near Lake Mahopac

Tarrytown is mightily changed in less than a hundred years, but there is that charm in the atmosphere that causes us to wonder not that the good wives gave it its name because their husbands were wont to linger there on market days.

Up the hill from the town and one may look back to the left for a fine view of the Hudson, with the manufacturing plant of the Maxwell-Briscoe Motor Company looming up prominently; then on to Scarboro and Briarcliff Manor. Here the road turns along past Echo Lake, and half a dozen miles farther on the first of the chain of beautiful Crotona lakes which assuage the thirst of New York comes into view. Passing the first bridge

The Dam at the West Branch Reservoir

the road runs alongside the lake with many a turn, each of which has some charming view to offer. Through Yorktown Heights and into Amawalk the road extends, and follows for

Just Before the Good Roads Were Reached

the entire length of the Muscoot reservoir, bearing northward until the beautiful Lake Mahopac is reached.

Over the bridge at the head of the West Branch reservoir the road leads on toward Carmel, then follow Brewster and Sodom, after which Peach Lake awaits in refreshing beauty, and by its side the State road. Then comes North Salem, with its rather lugubriously named resort, "The Port of Missing Men."

From this point the way is straight south to Bedford, through New Castle Corners to Armonk. In a few minutes more and the path is running along the east side of Kensico reservoir and then, suddenly, we are away from all country things and in the midst of the very citylike bustle of White Plains.

All that remains is the spin in through Yonkers to New York. In all less than 135 miles have been covered, and there is still time to dress for dinner.

Chadwick Gathers Laurels in Baltimore Climb

BALTIMORE, MD., June 20—The big event in the Baltimore hill climb, the free-for-all on Saturday last, was carried off with flying colors by the big 90-horsepower Chadwick car, entered by the Chadwick Engineering Works and driven by Len Zengle. The ascent was made in the remarkable time of 36 seconds flat for the six-tenths of a mile, breaking last year's record of 43 1-5 seconds. It is the opinion of motorists that this performance will stand unequaled for some time to come. For taking the honors in the feature event the Chadwick car gets the handsomest of the silver cups offered by the Automobile Club of Maryland, under whose auspices the climb was held.

There were two prizes offered in this event, the other one being for the four-cylinder car that made the best showing in the contest. This prize was captured by the 60-horsepower Stearns entered by Joel G. Nassauer, chairman of the committee which had the contest in hand, and driven by Clarence L. Hahn. This car negotiated the distance in 49 1-5 seconds. It must be understood that this car did not finish second, but it received the prize under the conditions of the race, which were made so as to give the amateur performers a chance to shine as well as the big fellows. The second car in the event was a 50-horsepower Matheson, entered by the Matheson Motor Car Campany, and driven by J. A. Turner. The time was 44 seconds. The third car was another Chadwick of 60 horsepower, which completed the ascent in 46 seconds. This entry was that of W. W. Lanahan and was driven by Wilfrid Smith.

The races began promptly on scheduled time, at 2 o'clock. They were held on the Belvedere Hill, from Falls avenue to Roland avenue, the grade of which is 15 per cent. With the exception of a rough starting place, the hill was in excellent condition. The mud on Belvedere avenue, just west of the Falls road, was very heavy because of the continued rainy weather and it was necessary to lay a large quantity of cinders.

There were nine other classes besides the free-for-all race and the motorcycle event. The time made by the winning cars in these events was considered very creditable. In addition to capturing the amateur prize in the free-for-all contest, the Stearns 60-horsepower car, entered by Joel G. Nassauer, also won two other events—the Class G for cars selling for $4,001 and over and Class K for amateur drivers only in cars selling for $3,001 and over. In the former event the car was driven by Clarence L. Hahn in 50 3-5 seconds, while in the amateur event Mr. Nassauer drove his car up the hill in 51 4-5 seconds.

Matheson cars were also conspicuous as winners, carrying off three of the events scheduled. In Class E and Class H the 50-horsepower Matheson car, entered by Edgar F. Dobson and driven by himself, was the winner. The former event was for cars selling for $2,001 to $3,000, while the Class H event was for amateur drivers only in cars selling for $3,000 and under. Mr. Dobson's time in the Class E event was 49 1-5 seconds, while in the amateur contest his time was 48 3-5 seconds. The other Matheson car to carry off the honors was in Class F for cars selling for $3,001 to $4,000. This car was driven by Guy Reynolds and entered by the Matheson Motor Car Company. The time was 47 seconds.

The 30- and 40-horsepower Buick cars entered by the Auto Outing Company won the Class C and Class D events. The former was for cars selling for $1,201 to $1,600 and the latter for cars selling for $1,601 to $2,000. In the Class C event the Buick. driven by G. B. Hall, made the climb in 57 1-5 seconds, while in Class D the Buick's time was 56 seconds flat. Charles Jenkins drove the car in this event.

Howard Bauer, in a 30-horsepower Oakland, entered by the Oakland Motor Car Company, was the winner in Class B for cars selling from $801 to $1,200. The time was 1.01. The opening event was taken by the Hupmobile entered by Little Joe's Auto Exchange and driven by T. Wilson Simpson. The little car made the distance in 1.21 1-2. The undertaking was conducted with the greatest care and praise was meted out freely by the contestants and the patrons of the event, who gathered in force at points of vantage.

Those in charge of the meeting were: Hill climb committee, J. G. Nassauer (chairman), H. M. Luzius and F. H. Hack, Jr.; referee and representative of A. A. A., Dr. H. M. Rowe; judges, C. Howard Milliken, Osborne I. Yellott and James Stone Reese; timers, Dixon C. Walker, Harry Weiler, F. S. Bliven and J. M. Zamoiski; technical committee, E. W. Orr, J. M. White and Lee Trembley; clerk of course, Thomas G. Young; starter, Howard A. French; assistant starter, Frank Olmstead; scorer, Thomas E. Brian; announcer, Harry E. Mayer. The summaries:

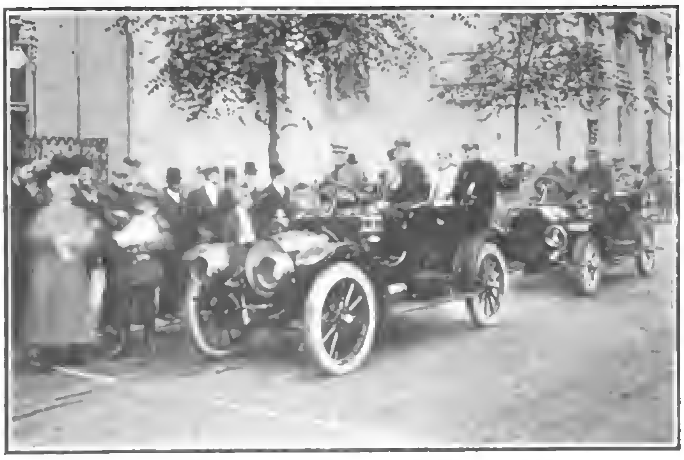
No.	Car.	H. P.	Driver.	Time.
Class A—$800 and under—				
1.	Hupmobile	20	T. W. Simpson	1.21 1-2
2.	Hupmobile	20	Nat Tuttle	1.43 1-2
Class B—$801 to $1,200—				
1.	Oakland	30	Howard Bauer	1.01
2.	Warren-Detroit	30	Harry Reis	1.06 1-2
3.	Ford	20	A. M. Eastwick	1.08 3-4
Class C—$1,201 to $1,600—				
1.	Buick	30	G. B. Hall	0.57 1-5
2.	E-M-F	30	M. C. Jones	1.05 1-2
3.	Crawford	28	A. A. Miller	1.07
Class D—$1,601 to $2,000—				
1.	Buick	40	Chas. Jenkins	0.56
2.	Oakland	30	Howard Bauer	0.56 1-2
3.	Buick	30	Geo. Jenkins	1.02
Class E—$2,001 to $3,000—				
1.	Matheson	50	E. F. Dobson	0.49 1-5
2.	Chalmers-Detroit	40	Jos. F. Janin	0.58 2-5
3.	Oldsmobile Special	40	C. R. Meisner	1.13 2-5
Class F—$3,001 to $4,000—				
1.	Matheson	50	Guy Reynolds	0.47
2.	Knox	40	John Goodwin	0.58 1-5
Class G—$4,001 and over—				
1.	Stearns	60	C. L. Hahn	0.50 3-5
2.	Chadwick	60	J. R. Dungan	0.52
Class H—Amateurs, $3,000 and under—				
1.	Matheson	50	E. F. Dobson	0.48 3-5
2.	Chalmers-Detroit	40	Harry Reis	0.56 1-5
3.	Crawford	28	Wm. Delon	1.03 2-5
Class K—Amateurs, $3,001 and over—				
1.	Stearns	60	J. G. Nassauer	0.51 4-5
2.	Chadwick	60	W. W. Lanahan	0.52
3.	Stearns	60	S. A. Nattans	1.28
Class L—Free-for-all—				
1.	Chadwick	90	Len Zengle	0.36
2.	Matheson	50	J. A. Turner	0.44
3.	Chadwick	60	Wilfrid Smith	0.46

Eleven Perfect-Score Cars in New Jersey Run

NEWARK, N. J., June 20—Under extraordinary conditions of road and weather, nineteen out of the total list of thirty-four starters in the annual endurance run of the New Jersey Automobile and Motor Club finished the full course Saturday. The distance was 290.6 miles—twice around a measured course of 145.3 miles. In perfect weather the run would prove difficult enough on account of its unusual length and stiff hills, but after a long series of rainstorms, which rendered the crowned roads perilous in places and the hills well-nigh unnegotiable, a cloudburst, tornado and a pelting hailstorm added just the touch necessary to make the trip answer to Sherman's definition of "War."

The blow fell during the first half of the second round, when most of the cars were in the vicinity of Green Pond Mountain, as difficult a bit of hill climbing as there is in this part of the country. Suddenly the black clouds emptied themselves and thousands of tons of icy pellets, propelled on the wings of a 60-mile wind, whistled about the heads of the contestants like the projectiles from a battery of machine guns.

Some of the cars had succumbed during the first round, but it was the hail that caused the vast bulk of the trouble. It put out a whole platoon of automobiles and left them standing at various points in the hills while their crews sought shelter in the mud and water under the cars.



Carlough's Perfect-Score Franklin at the Start

Eleven cars completed the run under these conditions with perfect scores and checked in on the minute in the presence of a vast crowd that lined the last mile of the course and surrounded the clubhouse in Newark. There would have been one more clean score if a series of street cars had not blocked Buick, No. 17,

Baby Maxwell on Road Between Dover and Bloomfield

about 200 yards from the finishing line, as the car was but 1 minute 52 seconds late.

The higher class runabouts made the best showing with four perfect scores and only two absentees at the finish.

There was a large amount of tire trouble all along the route and the tremendous grades and the mud brought on considerable carbureter difficulty and heating of the motors.

The course was from the Newark headquarters of the club, north to Newfoundland, west to Hackettstown, south to Flemington and east to Newark. The start was at 5 o'clock in the morning, and the finish at 8 o'clock at night.

The event was conducted under the direction of the contest committee, of which H. A. Bonnell, assistant general manager of the A. L. A. M., was chairman. Associated with Mr. Bonnell were A. B. Le Massena, secretary of the club,, F. C. J. Wiss, De Witt C. Reynolds and B. F. Hurd. The referee was Jacob Haussling. There was no technical examination of the cars after the finish, as under the conditions of the race the awards were made upon the showing of the cars on the road. The observers were drawn largely from the ranks of college students, but as the penalized cars did not finish in considerable numbers, their work was not heavy. The New Jersey laws prohibiting the use of

Humphreville's Hudson near Morristown

chains on some of the roads, while allowing them on other parts of the course, puzzled some of the drivers and injected an element of uncertainty in attempts to pass some of the cars on steep grades. The Simplex tore down a section of fence on the first round, but neither car nor crew suffered injury. Aside from that accidents were rare.

The course did not pass by directly the new country headquarters of the club near Butler. Work is being pushed on the additions to the splendid buildings and by next Saturday it is believed that the place will be ready for occupancy.

The tabular score of the run is as follows:

No.	Car.	H. P.	Entrant.	Score.
Class A—Touring cars listed at under $1,600				
34	Cadillac	30	I. M. Uppercu	Perfect
20	E-M-F	30	G. F. Eveland	Did not finish
26	Mitchell	30	F. L. C. Martin	Did not finish
32	Regal	30	E. S. Hilton	Stripped gear, did not fin.
Class B—Touring cars listed at $1,600 and over—				
15	Franklin	28	E. D. Carlough	Perfect
19	Buick	30	J. C. Bell	Perfect
28	Buick	30	James W. Ward	Perfect
17	Buick	30	J. C. Bell	2-points; late at finish.
9	Am. Simplex	50	H. F. Seibert	3-points; stalled motor
36	Packard	30	A. Hollendar	Disqualified; early at fin.
8	Auburn	32	J. J. Meyer	Withdrew after 1st round
11	Haynes	30	E. H. Paddock	Did not finish
18	Buick	30	J. C. Bell	Did not finish
21	Fiat	25	Philip Hilton	Did not finish
25	Selden	35	P. L. Munford	Did not finish
38	Johnson	30	Carl F. Johnson	Did not finish
Class C—Roadsters listed at under $1,200—				
24	Hudson	25	A. H. Humphreville	Perfect
27	Hupmobile	20	F. L. C. Martin	Perfect
29	Ford	20	L. J. Wycoff	Perfect
4	Maxwell	22	J. W. Mason	7-points; motor stops
5	Maxwell	14	J. W. Mason	15-points; motor stops
30	Hupmobile	20	F. L. C. Martin	Broke wheel at start
31	Overland	25	W. F. Ackor	Did not finish
33	Hupmobile	20	F. L. C. Martin	Did not finish
Class D—Roadsters listed at $1,200 and over—				
6	Maxwell	30	J. W. Mason	Perfect
10	Haynes	40	W. E. Shuttleworth	Perfect
22	Jackson	50	F. L. Kramer	Perfect
23	Columbia	29	W. J. Tynan	Perfect
14	Franklin	42	E. D. Carlough	1-point; stalled motor
35	Cadillac	30	I. M. Uppercu	3-points; motor stops
7	Overland	40	George L. Riess	70-points; lateness
3	Mercer	30	R. A. Greene	Finished after limit
37	Chalmers	30	Frank J. Radel	Did not finish
39	Haynes	30	James D. Rourke	Did not finish

Quaker City Summer Meet Marred by Storm

PHILADELPHIA, June 20—Rain put a stop to the fourth annual Summer race meet of the Quaker City Motor Club, at Point Breeze track, Saturday afternoon. E. R. Bergdoll in a Benz and Ralph De Palma in a Fiat were having a battle royal for the honors in the fifty-mile race, with the latter about 10 seconds in the lead, and the field strung along for miles behind, when the storm, which had been threatening for half an hour, came down upon the track. It wasn't an ordinary rainstorm; it was a cloudburst, with hail on the side, and in a minute the red flag was wig-wagging the contestants to shelter. Thirty miles had been covered when the race was stopped, and as De Palma had a fifty-yard advantage over Bergdoll when the race was called off, the officials awarded him first money.

When the storm loomed up in the west there were still two events to run off—the twenty-five mile and the fifty-mile. It was decided to start the latter, as the field was rather large, it was the big race of the day, and it was thought that there would be sufficient time to finish it. Two Klines, a Buick, a Chalmers-Detroit and a Jackson were the other starters. The twenty-five mile event was not run.

Bergdoll was the star of the meet. The local millionaire brewer had his Benz going fine, and he easily annexed the five and ten-mile events for amateurs, besides finishing second in the fifty-mile free-for-all. Scoot Miller won one of the five-mile events for smaller cars in his Warren-Detroit, the other going to the Otto, driven by G. Jones. The times were slow throughout, the only record broken being the track figures for five miles, De Palma clipping 1 3-5 seconds off the previous best of 5.14 3-5. One event which proved amusing, even if not exciting, was the mile "nearest to three minutes" race. There were thirty entries, and the contest resembled a funeral procession, and an exceedingly slow one at that. Gordon Dyer, in his Selden, was the best guesser of the bunch, landing his car under the wire in 3.00 2-5.

A pursuit race with four entries was won by Burns' Autocar, after which came the big race—and the deluge, which set the 15,000 in attendance scampering like mad for shelter.

Start of the Fifty-Mile Event, Which Was Stopped by the Storm

The Quakers are much gratified over the announcement of the early granting of the sanction for the third annual renewal of their Fairmount Park classic, which is scheduled for Saturday, October 8. The mayor and city councils are much interested in the race, it having been borne in upon them that an event which can entertain a half million people for half a day has something in it of advertising value for the city which many other happenings upon which the municipality spends money do not possess.

An ordinance has been introduced into councils to appropriate a sum of money to add to the prize list and thus insure a representative entry list. The number of inquiries at this early date is an indication that these makers are beginning to recognize the claim of the Q. C. M. C. Contest Committee that the Fairmount Park race has become the big long-distance event of the year. The summaries:

Five miles, amateur—Division 1-C—

Car.	Driver.	Time.
1. Benz	E. R. Bergdoll	6.01 4-5
2. Alco	W. C. Longstreth	
3. Kline Kar	Harvey Ringler	

Five miles—Division 2-C—

1. Warren-Detroit	Scoot Miller	5.55
2. Schacht	Jas. H. Gray	
3. Black Crow	James Blind	

Five miles—Division 3-C—

1. Otto	George Jones	6.04
2. Mercer	W. Oliver	
3. Pullman	J. Adee	

Ten miles, amateur—Division 4-C—

1. Benz	E. R. Bergdoll	11.42 4-5
2. Buick	Bardsley	
3. Chalmers	Richards	

One mile, free-for-all, nearest 3 minutes—

1. Selden	Gordon Dyer	3.00 2-5
2. Alco	W. C. Longstreth	

***Fifty miles, free-for-all—**

1. Fiat	Ralph De Palma	39.59
2. Benz	E. R. Bergdoll.	

Trial for five-mile track record—

1. Fiat	Ralph De Palma	5.13
2. Former record		5.14 2-5

*Race stopped at completion of thirty miles.

Georgia-Florida Good Roads Boost

The large illustration shows a sample of the roads the tourists found between Savannah and Jacksonville. The figures in the right lower corner are: A. J. Salinas, president of the Augusta Cotton Exchange; C. B. Garrett, president Augusta Automobile Club; Judge A. B. Moore, chairman Chatham County Board of Commissioners; F. C. Battey, president Savannah Automobile Club, and Judge Oliver T. Bacon—a bunch of "Good Roads Boosters."

SAVANNAH, GA., June 20—The recent convention of the Georgia Good Roads Federation and dual endurance run from Augusta and Jacksonville to this city was a pronounced success. The Augusta contingent, consisting of sixteen cars, was met nine miles out by half a hundred cars from the Savannah Automobile Club and escorted into the city. En route the travelers, after an early morning start, stopped for breakfast at Millen, where they were the guests of Mayor Daniel and the City Council.

From Millen the party continued until Statesboro was reached, where dinner was ready and served. The roads between these two cities were in poor shape. A delegation of good roadsters picked up at Millen included E. E. Chance, chairman of the County Commissioners; J. P. Palmer, superintendent of roads; J. L. Boyd, one of the County Commissioners, and G. F. Storey.

On reaching Savannah a parade was formed and something like ten thousand people watched the cars as they rolled down the beautiful Main street of Savannah and around part of the Grand Prize race course to the yacht club, where a big luncheon awaited them.

But twelve cars made the two-day trip from Jacksonville to this city. The reason given is because one of the largest and hottest elections ever held in the State was on. The start was made early in the morning and the cars traveled over the same course as that of the Savannah Automobile Club during the month of April. The night stop was made at Brunswick.

Between three and four hundred were in attendance at the third meeting of the Georgia Federation of Good Roads Authorities, of which the two runs were a feature. Besides delegates from each county in the State there were several representatives from several counties in Florida and South Carolina. The following officers were elected: President, William F. Eve, of Augusta; secretary, J. C. Harper, Augusta; vice-president, W. H. Moore, Statesboro; N. F. Tift, Albany; F. Sheffield, Sumter County; R. H. Drake, of Griffin; W. M. Gammon, of Rome; W. S. Holma, of Athens. Albany was selected as the 1911 convention city.

Speeches were made by Mayor Tiedeman, who welcomed the visitors and extended them the freedom of Savannah; Judge William F. Eve, of Augusta; J. E. Pennybacker, expert from road department of the Department of Agriculture; F. H. Opper, an expert on road material; Prof. C. H. Strahan, of the Engineering Department of the University of Georgia, Athens; Frank F. Battey, of the Savannah Automobile Club, and Judge W. M. Gammon, of Rome.

After the convention the visitors were taken out to several of the county farms and shown how work progressed here with the convicts. At several of these places lunch was served and a trip around the twenty-five miles of the famous Grand Prize race course was taken. After this a trip was made to the Casino at Thunderbolt, where a banquet and speechmaking were in order.

The following cars made the trip from Jacksonville and Augusta:

Car	H.P.	Entrant	Driver
JACKSONVILLE TO SAVANNAH			
Oldsmobile	40	Hugh Barnes	Hugh Barnes
Ford	20	L. C. Oliver	L. C. Oliver
Ford	20	H. B. Race	H. B. Race

Testing Steel—For Impact, Bending, Etc.*

(First Installment)

> **This paper presents, in a most capable way, an exposé of the methods employed and conclusions reached in two previous papers on this subject. In the two earlier papers it is pointed out that, while notched-bar testing has its value, it also has the hidden misfortune of casting reflections on good material. The authors employ some of the latest methods of determining the values they set out to fix, and the paper presents an exhaustive treatise on the subject from the several points of view.**

INTRODUCTORY—The general impression conveyed by the two papers† on Impact Testing of Steel, read in November, 1908, before this institution by Dr. Stanton and by Mr. Harbord,** was that, with notched test-pieces broken at one blow, the results were too erratic to be of real practical value except in special cases. This was contested at the time and there were some expressions of opinion that tensile-impact tests, on unnotched bars, were in many ways preferable; it appeared, therefore, desirable to examine the matter more in detail. It is undoubted that a notched-bar impact test will discover any inferior material, for in this case all the impact figures will be low. But it is also quite possible that good material may be condemned when only a single test is made, should it happen that this test-piece gave an abnormally low result. To take the average of a large number of test-pieces is not satisfactory, because the element of doubt remains whether the disparities are due to want of uniformity in the material itself or to errors in the measurements. The view, as expressed in those two papers, would appear to be that the measurements were at fault, but there is other evidence that the microstructure of the material is in reality the main cause.‡ It is to be observed that in a notched bar, ruptured at one blow by cross-breaking, it is the material at the bottom of the notch that has to bear the brunt of the impact, and it has not time to receive support from the bulk of the material. Should the microstructure, or it may be the macrostructure, at the bottom of the notch be weak, a low impact figure will be obtained. In actual use in a piece of mechanism, however, where anything in the nature of a notch is avoided so far as the design will admit, the contiguous portions of the material assist each other, and therefore weaknesses of the order of magnitude of the microstructure or even of the macrostructure are more or less obliterated by the stronger portions.

Following this argument, it would appear that, for an impact test to be of practical value, it ought to bring the whole of the material, in the cross-section under observation, simultaneously under the influence of the impact stress. A one-blow tensile-impact test on an unnotched test-piece fulfills this condition, and it is to be observed that M. Pierre Breuil, after collating a large number of the published results of various methods of impact testing and adding thereto many of his own, has come to the same conclusion.§

In the discussion on Dr. Stanton's and Mr. Harbord's papers Mr. Bertram Blount referred to a tensile-impact testing machine devised with the assistance of Mr. Hurry —to whom the idea was largely due—and an abstract of some of the preliminary results were given. It was decided to continue these experiments on a larger and more comprehensive scale and compare the results obtained with the usual static tensile tests.

On reviewing the matter, however, it was thought that the height of drop available, namely 6 feet, with this machine was insufficient, and that therefore the machine should be re-designed so as to admit of a drop of about 30 or even 40 feet, so as to obtain a striking velocity of 40 to 50 feet per second. By the foresight of the late Mr. David Kirkaldy, trap doors had been provided on the various floors of his testing works to accommodate a falling-weight apparatus, and owing to the facilities thus afforded the new machine was readily installed on the removal of the original one.

The new apparatus was designed upon the following principles, as distinct from the previous apparatus. The fall was to be a free fall, entirely independent of any sliding upon guides. The specimen was to move with the weight so as to avoid the complications arising when a tup is allowed to fall upon a stationary cradle, wherein the specimen is held, as the effects of inertia have then to be allowed for.

The machine being of the one-blow type, the only energy measurement required was the determination of the energy

* Paper read before the Institution of Mechanical Engineers (Great Britain) May 27, 1910. Presented by Bertram Blount, W. G. Kirkaldy, Member, and Capt H. Riall Sankey, R.E. (ret.), Member of Council.

§ "Revue de Mécanique," 1908, page 537.

remaining in the tup immediately after rupture of the specimen. There are many ways of measuring this energy, such as receiving the tup upon a spring and observing the amount by which the spring is shortened, or compressing air in a cylinder and determining the increase of pressure.

The former method has been adopted in similar impact-tensile machines, and the latter appeared promising, but after much discussion it was decided, at the suggestion of Mr. W. J. Marshall, A.I.Mech.E., to measure the actual velocity of the tup just after the moment of fracture of the test-piece, by observing the time-interval between the breaking of electric contacts at known distances apart. It is, of course, easy to deduce the energy remaining in the tup after fracture so soon as this velocity is known. The actual apparatus will be described later.

In order that these impact tests should have as great a practical value as possible they were made with a considerable number of the types of steels used in mechanical engineering. The original machine was designed to break test-pieces 1-4-inch diameter, and this diameter had been adopted and all the test-pieces machined accordingly before the new machine was designed. It was, however, decided later to make another series of tests with specimens 0.357-inch diameter to take advantage of the greater capacity of the new machine; the effective length for extension was 2 inches. The ordinary tensile tests were carried out, not only with test-pieces of standard size, but also with smaller test-pieces of the same size as the impact-tensile test-pieces, namely, 0.357-inch diameter. A full chemical analysis was also made. In this way it was possible to establish a comparison of the tensile impact tests with the usual methods of determining the characteristics of steel. A further comparison was also established by making a series of tests with a repeated-bending machine of the type described by Captain Sankey in the discussion on Mr. Harbord's paper, and on which further particulars are given later.

In every case the material was tested exactly as received from the manufacturers; that is to say, in the condition in which it would be actually sent out for use. It is considered that this is a matter of great importance because the mechanical characteristics of steel are affected by heat and other treatments.

Types of Steel Tested.—The authors gratefully acknowledge that, by the intermediary of the secretary of the Engineering Standards Committee, a number of makers were good enough to supply the various types of steel tested in accordance with the British Standard specification of each type; with one exception, however, namely the steel suitable for motor-car crankshafts, etc., which was purchased.

Refinements in Point of Detail for 1911

ONE of the principal causes of accidents to automobile drivers and owners is due to starting with the gears in mesh, someone having possibly meddled with the levers, placing one of them in mesh while the owner or driver was away. A lock which would dispense with this trouble would also reduce the number of cars stolen, for if it would prevent shifting of the levers, it would render the car inoperative.

A lock of this character has been designed and placed on the market by a Detroit concern, the Autö Sure Lock Company, which has not alone these salient points of merit, but also is simple and very low in price.

This device is called the Sure Lock, and although the first one to be brought out was designed for Cadillac cars, and especially fits that make, the lock is suitable for any make of car having a similar gear-shifting quadrant. Others are being brought out for other makes of cars, having a different quadrant. Such is the merit of the little device that the Cadillac Motor Car Company has taken it up and listed it in their catalogues as an extra.

The device consists of a brass plug, with a lock attached to the upper end by a strong chain, while the lower end of the plug carries a lug or ear with a hole for the lock to go through. The padlock is of the Corbin make, and two keys are supplied. In size, the whole thing is small enough to be conveniently carried in the side pocket of one's coat.

Fig. 1—Showing application of lock to the side lever which makes the car thief-proof

In the upper end of the plug there is milled a notch, just the size of the hand lever at the level of the top of the quadrant. One of the sides of the plug carries down in a long extension, which is both wide and thick—so wide and thick, in fact, as to take up the space in the shifting fork that the hand lever takes up when shifted over, making it possible to shift the lever to that side. Similarily the hand lever might be shifted over to the other side, but the long extension would then come directly in line with the stationary bars of the quadrant, and thus prevent any forward or backward motion. The hand lever is thus to all intents and purposes not movable, without unlocking the padlock, removing it, and then removing the brass plug. The latter may not be removed without unlocking the padlock, on account of the size and shape of both the shifting fork and the extension of the brass plug, designed for this purpose.

Fig. 2—The lock and the parts that go with it before applied to the side lever

While probably not appealing to people of small towns and the country, this device is practically a necessity for city use, and by reason of its low price and inherent simplicity, should soon have a great vogue there. The peace of mind and protection of knowing that one's car is perfectly safe, through a thoroughly good preventive device rather than something on the cure-afterward order, should make for wide sales. As stated, the company is working on a number of other models, and soon one will he able to secure a Sure Lock for any make of car.

1911 Ideas for Preventing the Growth of Noise

The question of how long an automobile will last has received some attention at the hands of users, and to some extent the purchasing of successive models year after year has been due to the fact that while the old automobiles were capable of running, they nevertheless offered food for serious reflection because they became noisy. This together with the rate of speed at which bodies went out of style represent the two serious matters which will have to be dealt with in the long run, but it is gratifying to note that the progressive makers of cars are not awaiting the decision of the buying public. Fig. 4 is offered to illustrate the new trend. This is taken from the new "Silent Six" Matheson, and shows grease cups G1 and G2 in a get-at-able position outside of the chassis frame. These cups feed grease to the bearings of the shafts which support the clutch and brake pedals. In the earlier types of automobiles, designers labored under the impression that the bearings of parts which did not rotate were not entitled to their serious consideration. They are slowly learnning, however, that there is something more than the mere question of the incidental operation of an automobile. The considerable number of small bearings scattered around the chassis, even though they may not have to withstand the rack due to rotation and high pressure, do, nevertheless, become the sources of unbearable noise unless the bearings are sealed by grease so that dust cannot enter, and serve as an abrasive substance introducing excessive "shake" and its companion, noise. It takes quite a numher of these grease cups to properly care for all the non-rotating small bearings in a car, but it is almost a waste of time and cost to introduce them, unless care is exercised to so locate them that an autoist, even though he may not be familiar with the inner intricacies of the mechanism, will be able to ohserve by a superficial inspection that they are present, in which event his good sense will permit him to inquire as to the reason for their presence, and if they are accessible, he will be inclined to give them the care and attention which are in keeping with the great importance of this part of the automobile subject.

Fig. 3—Illustrating the method of applying the parts in assembling

Fig. 4—Part of the Matheson "Silent Six" showing an application of grease cups

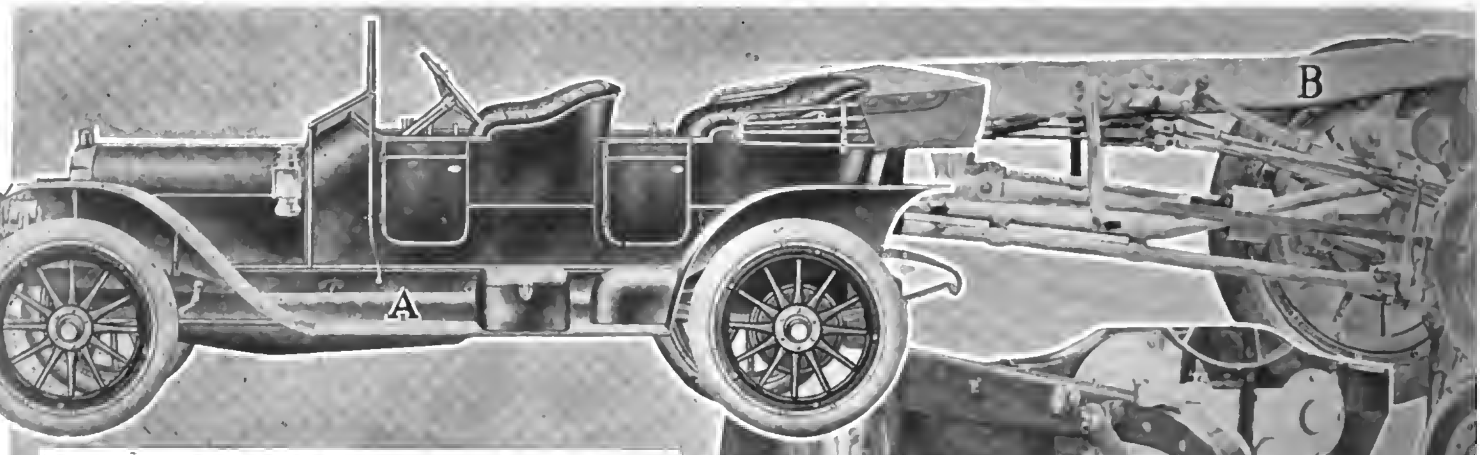
To the autoist who wishes to get good service out of his car, without having to pay too much by way of cost of maintenance, it is not too much to state that empty grease cups offer no possible advantage: it is necessary to keep them constantly filled with grease.

Knox Comes Out with 1911 Models

THE discontinuance by leading firms of American automobile makers of the custom of turning out yearly models is an indication that the industry is approaching that acme of perfection in design and construction which is the goal of all who strive to excel. The Knox Automobile Company, of Springfield, Mass., for instance, has approached so near perfection in general construction that it has decided to abandon yearly models, preferring to incorporate and put on its cars any slight changes or meritorious features as soon as they have been approved by the experimental and testing departments. This innovation will doubtless prove of decided benefit to Knox owners, agents and customers, present and future, as it insures a continuance of the general features of the various models for years to come. In Knox cars, indeed, are incorporated the same general construction features that have been so pronounced since the introduction of the water-cooled types in 1907. The original ideas have been developed entirely in the engineering department, under the supervision of Herman G. Farr. The steady advancement of the Knox product is due to conservatism in working out details of construction and careful consideration of even the slightest changes before they are adopted.

Torpedo fronts will he a feature of 1911 Knox body types except the closed cars, all bodies being made from steel and aluminum over wood frames and designed and built in the company's body works. They include five- and seven-passenger touring cars with torpedo-type front, five-passenger tonneauettes, raceabouts and regular torpedo types, all made with flush sides, except that the touring car tonneaus widen out back of the rear doors, as do also the tonneauettes, the tonneaus of which are made detachable. The different types of 1911 models will be designated by series, the classes to be known as Model R, four-cylinder, 40-horsepower, and the Model S, six-cylinder, 60-horsepower, as in 1910. Comparison of the 1911 models with those of last year brings to light a few minor changes in construction, among which may be mentioned the lengthening of the Model R wheelbase to 121 1-2 inches, and the placing of the front axle 1 1-2 inches farther forward than in the 1910 design. The rear springs are lengthened to 58 inches over-all, and 5 inches have been added to the length of the top half, or scroll, improving the good riding qualities. Rear axles are Knox full floating type, running on Hess-Bright annular ball bearings. The entire differential is easily dismounted if necessary. Torsion rods will be used on full floating axles. Frames are made of heavy-gauge nickel steel with deep side channels and wide flanges. A slight change has also been made in the 1911 transmission, due to the use of double annular bearings at the rear of the transmission and also in the rear bearing of the lay shaft—both these changes making for quieter running on the intermediate and low gears. A change in the front timing gear is the adoption of a cast-iron magneto idle gear in place of that of fiber used in the 1910 models. There has also been a change of price, the 1911 Model R being quoted at $3,300 instead of $3,250, the prices of the Model S series remaining unaltered.

The Knox power plants for 1911 will retain all of the features that have made them so satisfactory and successful ever since the water-cooled motors were adopted—i. e., unit construction and three-point suspension; valves in the heads, with detachable heads; force-feed system of lubrication; side arms of the yoke are detachable and bolted to the sides of the crankcase at the rear, and with the transmission case forming the rear of the yoke. An exceptionally wide flat-tube radiator is used on both models, thus avoiding overheating.



KNOX TECHNICAL REFINEMENTS FOR 1911

(A) General view of the 1911 tonneauette, series A, showing side doors for front and back seats, a graceful overhang dash effect, well regulated height of the running board, flaring mudguards which not only protect the chassis but are so shaped that they will not rattle loose, and become a source of noise and annoyance.

(B) The rear end of the chassis, showing three-quarter elliptic springs with a secure double U-bolt anchorage, wide leaves, and ample clearance at the shackles so that when the springs depress the semi-elliptic lower portion will not interfere with the movement of the half-elliptic upper portion—the springs are aided by shock absorbers, are sufficiently long to make the vertical movement slow, and have retainers. The torsion rods are shown of tubular material, and so centered that the relative motions are in correct relation, and of sufficient strength to resist the torsion of the rear axle. The frame of the channel section is of the drop type, is strongly supported at the rear, and pressed steel members are employed to the exclusion of castings. This particular illustration represents the Model R 1911 construction.

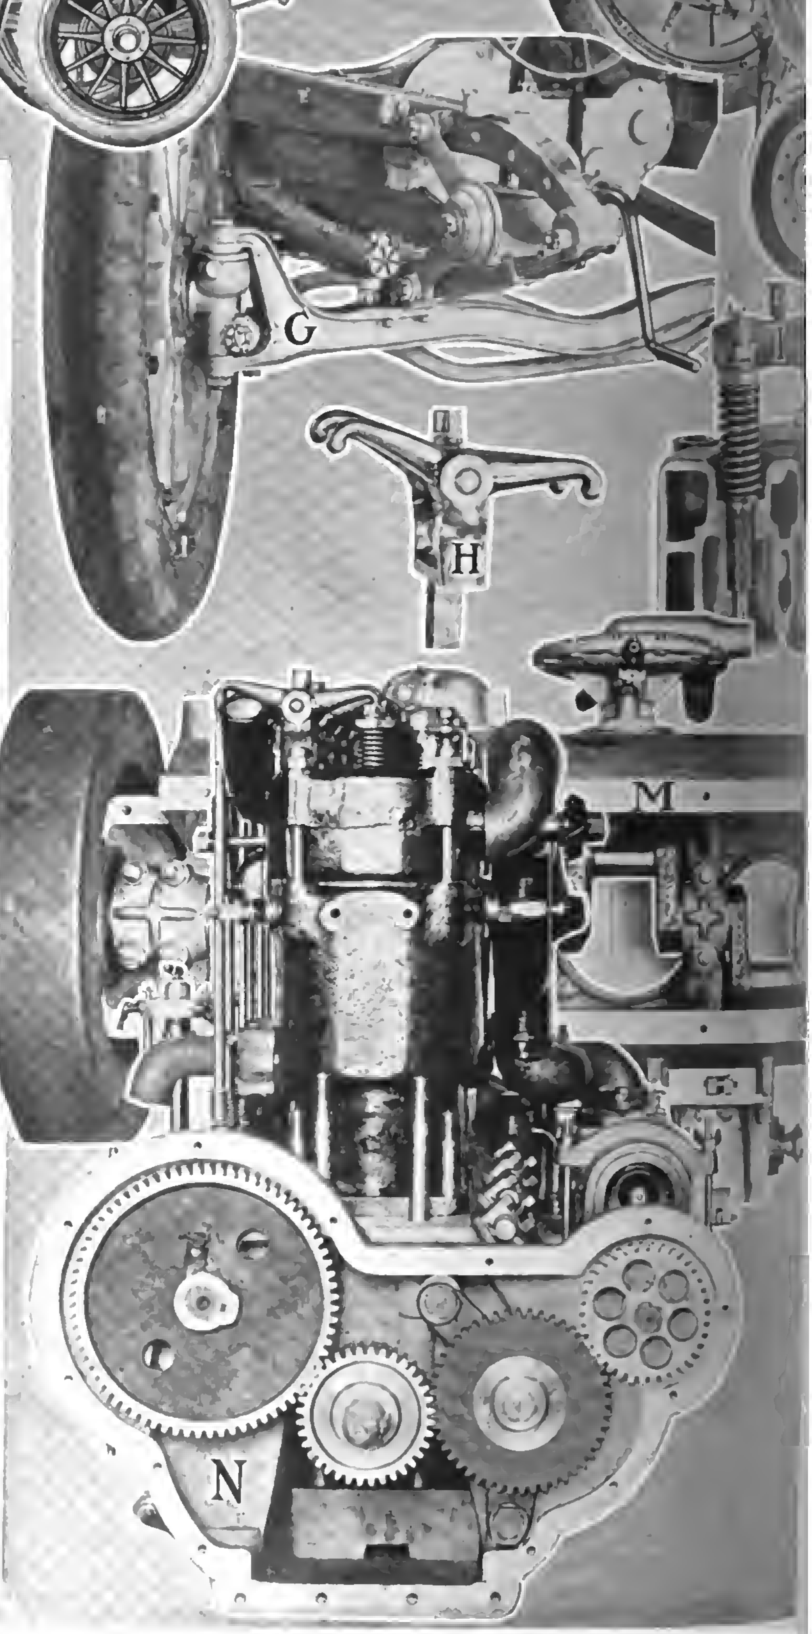
(C) Shows the brake drums separated, also the holes which are used for bolting them to the hub flanges.

(D) The brake construction shows a drum of large diameter with an internal expanding shoe actuated by an oval cam, and an external constricting band actuated by a Napierian toggle system. The shoes are faced with fireproof fabric, and the area exposed is sufficient to afford the requisite breaking effort, to snub the motion of the car and bring it to rest without having to compress the material to a point where it will lose its fiber-like ability.

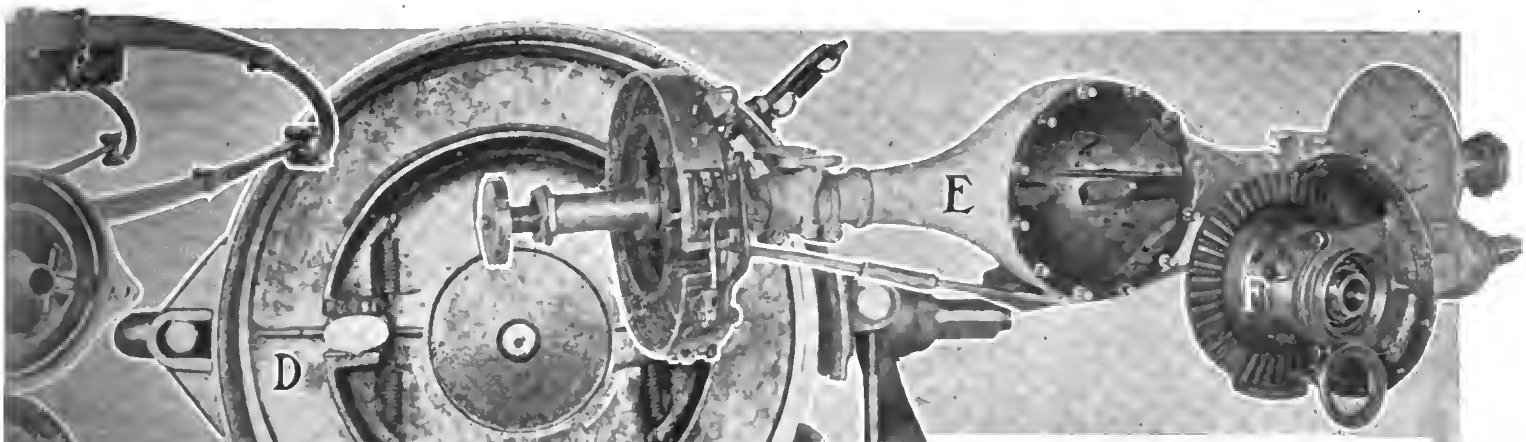
(E) Full floating type of live rear axle running on annular type Hess-Bright ball bearings, showing the brake bands in place, the enlargement at the mid position to accommodate the compensating gear and bevel drive, the bracing to prevent sag, and the spring perches so arranged as to be free to rotate on the shaft.

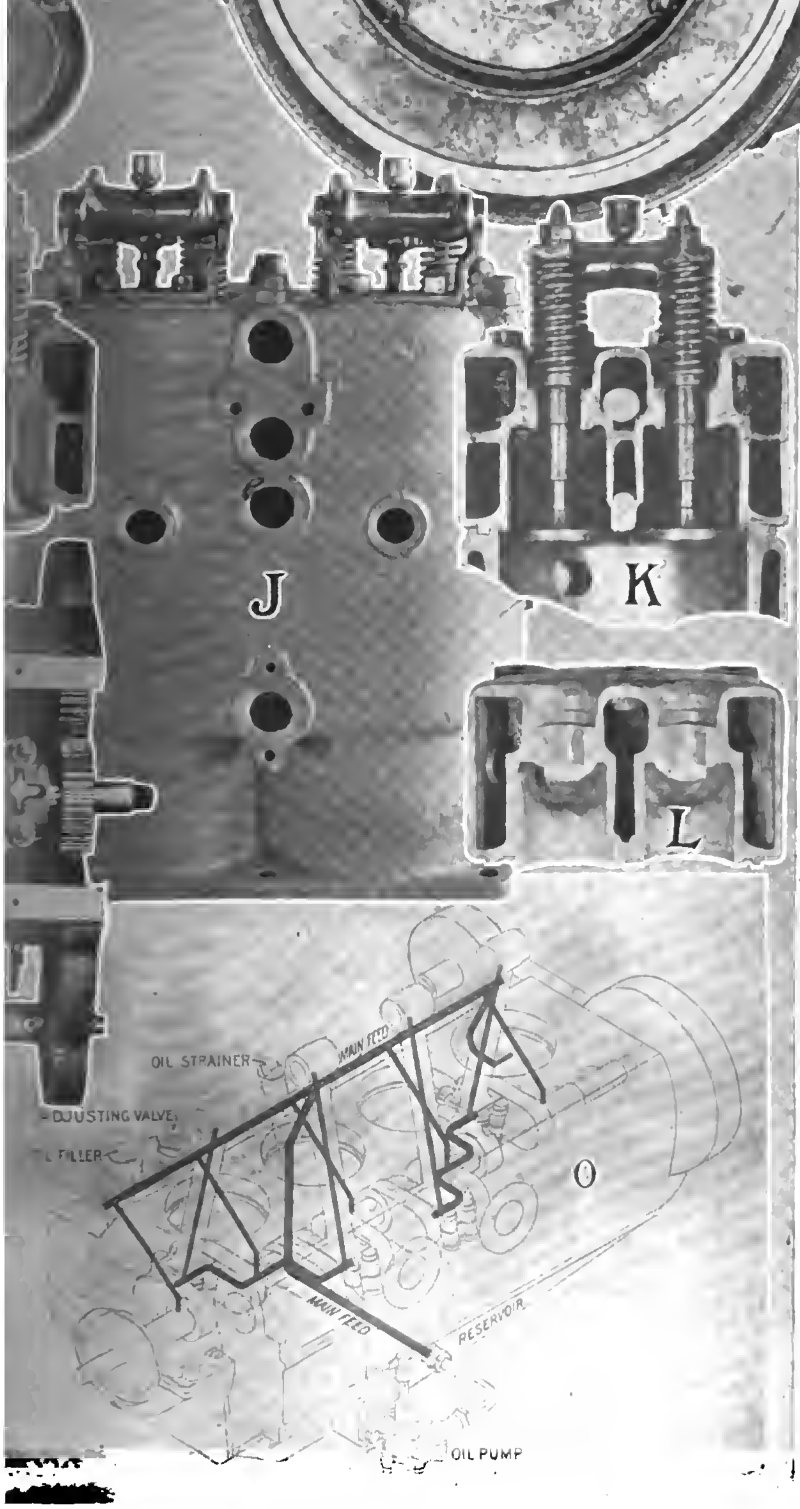
(F) The bevel drive and differential system removed from the enlargement of the live rear axle housing as shown at E, disclosing the use of annular type ball bearings, and a unit method of assembling so that the whole system may be removed from the housing at will for the purpose of inspection, adjustment or repair. The bevel drive is noiseless in operation, due to the excellence of the work done, and further to the fact that the unit method of assembling permits of adjusting the pinion in relation to the gears so that they run on the pitch line.

(G) Front axle of I-section forged steel without a weld, using the Elliott type of knuckle and a through pin with adequate means for locking. The termination of the chassis frame and its engagement with a half-elliptic spring, showing how the shock absorbers are securely fastened, and the cross member in front, which serves as the support for the motor, the lower half of which is in place to indicate how the starting crank extends out and drops down clear of the front axle. The wheel is turned, presenting a view of the knuckle, and it is interesting to note that the distance between the center line of the knuckle pin and the center of the wheel is sufficiently restricted to make steering an easy matter.



DEPICTING THE MECHANICAL NICETIES OF THE KNOX 1911





AS PORTRAYED BY THE CAMERA

(H) Before glancing at the cylinder J, attention is called to the stout design of the valve rockers which are a part of the valve mechanism, and the relation of these parts will best be appreciated by examining the front end view of the motor M, which presents these members as they attach by means of rocker pins in yokes which in turn bolt to the tops of the cylinders.

(I) The valve head is here shown in section; it bolts to the top of the cylinders as shown at J, and the valves, being of the overhead type, are inserted in their guides in the head before it is placed on the top of the cylinders and bolted down. The section shows how well the head is water-jacketed, and how the valve springs rest upon a finished seat which is cooled all around.

(J) The cylinders are cast in pairs and are shown here with a separable head bo ted into place, and in this view the overhead valve system is shown to its natural size, affording an excellent opportunity to observe the entire harmony in the relations.

(K) This is another section of the cylinder and valve head which is given to show how the joint is made between the separable head and the cylinder. A tongue fits into a groove, and the joints are ground tight, so that while packing is eliminated, it is also true of this method that it makes the assembling easy in view of the self-centering relation.

(L) This view of a section of the head offers further evidence of the excellence of the water-jacketing system, and indicates the perfectly smooth and non-tortuous transfer ports for the incoming mixture and the exhaust; due to the excellence of design as here indicated the depression in the intake is reduced to a minimum, and back pressure of the exhaust is substantially obviated.

(M) This view shows the underside of the crankbox with the lower half removed, affording a view of the main bearings with the crankshaft in place, presenting the halftime gears at the front end, and the large main bearing next to the flywheel. The flywheel is also shown in place, and an opportunity is afforded to see how it overhangs so that the weight is taken off of the crankshaft to the maximum possible extent.

(N) End view of the motor at the front end, showing the halftime gears with the protecting cover removed, also the gear which drives the magneto. The oil well appears at the bottom and the cylinders are shown bolted in place, affording an excellent view of the valve mechanism, and disclosing the widest measure of accessibility.

(O) Shadowgraph of the crankbox showing the methods of oiling, with the oil pump fastened to the lower half, affording a hydraulic grade for the oil out of the well into the pump. The pump is placed vertically, and the driving shaft with its safety spring dog are shown. The system of piping is brought out in heavy shading, and arrows indicate the direction of the flow of the lubricant as it circulates through the system positively due to the force of the gear pump. The oil filler, oil strainer, and adjusting valves are shown in an accessib'e position, so that the autoist on the road is enabled to replenish the oil, adjust the feed, and clean the strainer without trouble.

UTOMOBILES AND SHOWING THE RELATIONS OF THE UNITS

The selling prices include full car equipment, as in 1910, including top, glass front, speedometer and clock, shock absorbers, baggage rack, Prest-O-Lite, nickel or brass trimmings, combination oil and electric side lights and tail light, Fiske demountable rims, tire cover, tire iron, horn, tire outfit and set of tools.

The prices for Knox cars for 1911 will remain practically unchanged, the Model R touring car with regular body being now listed at $3,300 instead of $3,250, the price of last year's model. In the Model S six-cylinder the touring car sells for $5,000 with front seat doors, and the limousine at $6,000. The other types are listed as follows: Close-coupled with front seat doors, $4,900; tonneauette with detachable tonneau, $4,900; torpedo type, six passengers, $5,000; double rumble raceabout, $4,800; standard 106-inch wheelbase raceabout or runabout, $4,700.

In the Model R, besides the touring car at $3,300, there are the tonneauette with regular front, $3,250; tonneauette with torpedo front and high doors, $3,350; close-coupled type, $3,250; torpedo type, $3,400; double rumble raceabout with torpedo front, $3,300; standard raceabout, 104-inch wheelbase, $3,200; seven-passenger limousine, $4,250; special folding landaulet, six-passenger, $4,250.

Fisk bolted-on tires with detachable rims will be the regular Knox equipment for 1911, 36 x 4 1-2 for Model R and 38 x 5 1-2 for Model S. In the raceabouts the purchaser will be given the option of 34 or 36-inch wheels.

How the Cadillac "Thirty" Is Made

PRICEWISE this car sells for $1,600. The standard equipment as given in the specifications is included. The remaining important matters, which are here to be discussed, involve the methods of manufacture and the details of design. In order to give the reader a capable insight into the details of design of the car, working drawings were reproduced by the wax process and are here given as follows:

Fig. 1.—Assembly of the clutch showing a section of the flywheel, the truncated cone member, and the clutch, which is made of pressed steel, also the sleeve, clutch spring, method of adjusting the spring tension, ball bearings for taking thrusts, and the control mechanism with a distance rod which fixes the relations with a view to preventing lost motion, which distance rod extends from an eye in the end of the trunnion fork to its anchorage on a lug which extends down from the front end of the transmission gear case.

Fig. 2 shows the motor in part section, longitudinally, and a cross-section of the same cutting through one of the cylinders, exposing a section of the piston, also the connecting rod, and giving relations of the half-time gears, besides indicating how lubricant is stored in a well in the bottom of the case. The longitudinal section, in addition to showing the flanging of the lower half of the crankbox, also affords details of the methods employed for driving the fan in front, and presents the section detail of the fastening of the copper water-jacket to the cast gray-iron cylinder, which is an important innovation in Cadillac work. The camshaft is also shown in part, being cut away at the front end, which does not prevent indicating the method of engagement of the valve lift through a roller which rides on the cam, and the means of adjustment which are necessary for the proper timing of the motor. The cylinders, according to this construction, are machined on the inside and outside, so that any imperfections which may be concealed under the skin as the cylinders come from the foundry are bound to be discovered. It is also a feature of this type of cylinder construction that the cooling will be much more efficacious, due to the fact that the heat transfer is on a more efficient basis, it being well understood that the heat conductivity of the hard skin on the surface of a casting is not nearly up to the level of that which obtains for the section of the metal under the skin.

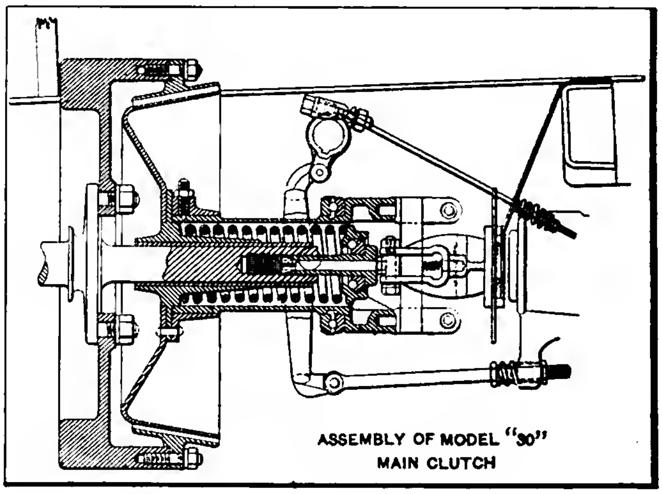


Fig. 1

Fig. 3.—Cross-section of the steering gear, which is of the worm-and-sector type, with ball thrust bearings at the extremities of the worm, with a grease-tight housing, and a ratchet on the sector shaft, which is there placed for the purpose of adjusting the worm and sector, with a view to the elimination of lost motion. The designer recognized the futility of providing an adjustment of this sort in the absence of some means for compensating for wear, and this important detail, by way of compensation, is accomplished in a very simple manner. The pitch line of the sector is not to unit radius. In other words, the sector is so shaped that as wear creeps in the eccentric bearings may be adjusted so that the sector will travel toward the worm, and the differences due to wear are

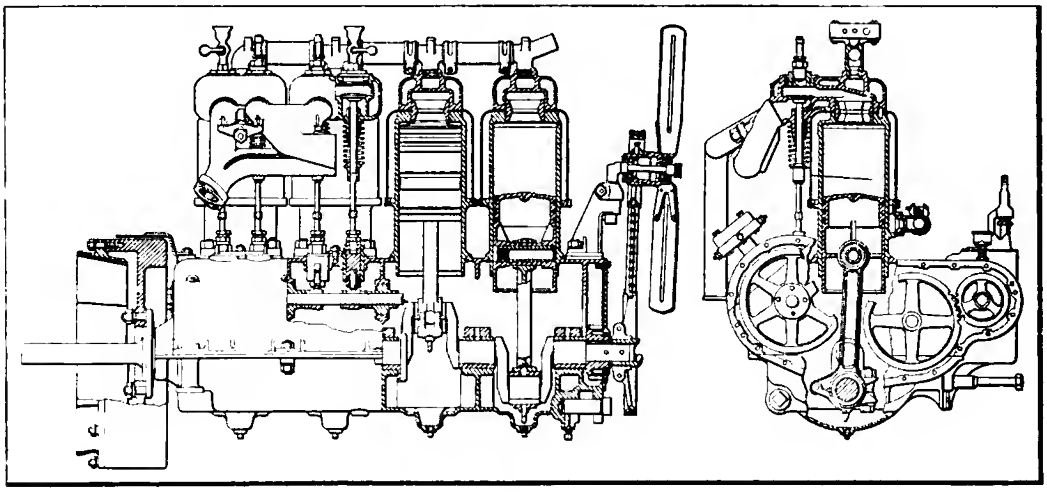

Fig. 2

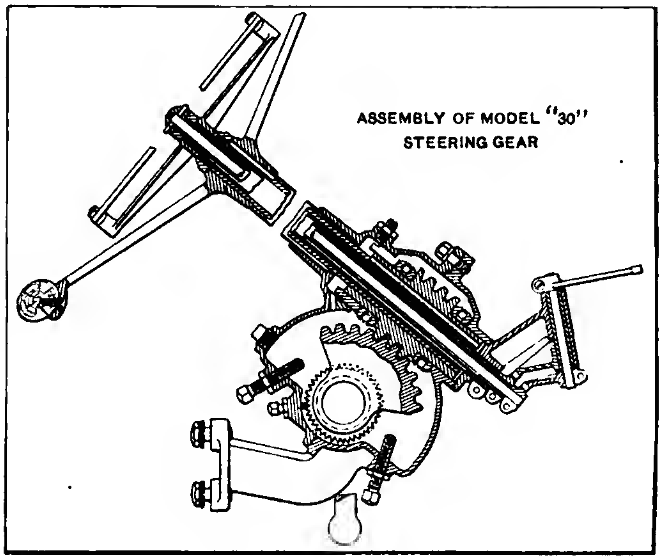

Fig. 3

neglected with impunity. In other respects, the steering gear is substantially made with provision for the spark and throttle control on the top of the wheel, and a lever system at the lower end, which transmits the motions of the spark and throttle lever for their intended purpose. The method of anchoring the steering-gear housing to a lateral of the chassis frame includes a stout arm integral with the housing, and a crow-foot on the extremity, which is faced off to make a good bearing, so that the holding bolts which pass through the lateral of the chassis frame are enabled to do their proper work. The steering wheel is of large diameter, with a substantial metal portion, and it is accurately fitted to the tube, and properly keyed, so that the autoist is introduced to neatness, comfort, and safety when he takes the wheel in this car.

Fig. 4 presents the transmission gear in section, the universal joints of the protruding shafts, also a section of one of the universal joints and a section of the selector. Glancing at the section of the transmission gear, it will be observed that it is of the three-speed selective type, that the gears are wide-faced, of symmetrical design, and are secured to the shafts (a) by riveting to integral flanges on the lay shaft, and (b) the sliding gears are accurately fitted to a square shaft. The shafts are of unusual diameter, and relatively short, so that they possess to a degree the measure of rigidity which aborts deformations. It is scarcely necessary to point out that in many of the older designs of automobiles this question of rigidity was neglected, the shafts were made long and relatively small in diameter, they deflected under the load, and the gears declined to slide. The universal joints are fetched up on a slow taper, so that with the pressure, which is exerted by the locking nuts, they are in sufficiently secure relation to transmit the torque of the motor even in the absence of keys, but with a view to proper insurance, a well-fitted key is used in each case.

Every effort is made in the manufacture of the units, as well as in the automobile complete, to have absolute interchangeability of parts, and the facilities afforded in the Cadillac plant are of a studied character, it being appreciated that this end cannot be secured unless the personal equation is eliminated.

SPECIFICATIONS OF THE CADILLAC "THIRTY"

Motor—Four-cylinder, four-cycle; cylinders cast singly; 4¼ inch bore by 4½ inch stroke. Five-bearing crank shaft.
Horsepower—Nominal 30. Actual, dynamometer tests, 33.
Cooling—Water. Copper jacketed cylinders, gear driven gear pump. Radiator of ample efficiency. Fan attached to motor, running on two point ball bearings. Center distances of fan pulleys adjustable to take up stretch in belt.
Ignition—Two new systems, complete and independent—low tension magneto; four unit coil with dry cells.
Lubrication—Automatic splash system, oil uniformly distributed. Supply maintained by mechanical force feed lubricator with positive sight feed on dash.
Carbureter—Float feed type.
Clutch—Cone type, leather faced, with special spring ring in fly wheel.
Transmission—Sliding gear, selective type, three speeds forward and reverse.
Drive—Direct shaft drive in housing to bevel gears of special cut teeth to afford maximum strength. Universal joint. enclosed in housing and running in oil bath.
Axles—Rear, special alloy steel live axle shafts running on special roller and ball bearings. Front, "I" beam section with drop forged yokes, spring perches, tie rod ends and steering spindles, the latter having ball thrust bearings.
Brakes—One internal and one external brake direct on wheels, large drums, double acting and compensating.
Steering Gear—Worm-and-sector type, adjustable, with ball thrust bearings.
Frame—Dropped, pressed steel, channel section. Width, 30 inches in front, 33 inches in rear.
Wheels—Wood, artillery type, with quick detachable rims. Special large hub flanges and special strength wide spokes.
Wheel Base—110 inches.
Tires—34 x 4 inches.
Tread—56 inches.
Springs—Front, semi-elliptical, 36 inches long by 2 inches wide. Rear, three-quarter platform; sides, 42 inches long by 2 inches wide; rear, 38 inches long by 2 inches wide.
Control—Spark and throttle levers at steering wheel. Steering wheel 17 inches in diameter. Clutch operated by foot pedal. Service brake (external) operated by foot lever. Emergency brake (internal) operated by hand lever. Speed changes by hand lever operating in "H" plate. Throttle acceleration by foot lever.
Speed—5 to 50 miles an hour on high gear.
Gasoline Capacity—About 13 gallons.
Oil Capacity—Six pints. Sufficient for 400 to 500 miles.
Upholstering—Black leather over genuine curled hair and deep coil seat springs.
Finish—Royal blue body and chassis striped.
Equipment—One pair gas lamps and generator; one pair side oil lamps and tail lamp, magneto, horn, set of tools, pump, tire repair kit, robe rail and tire irons.

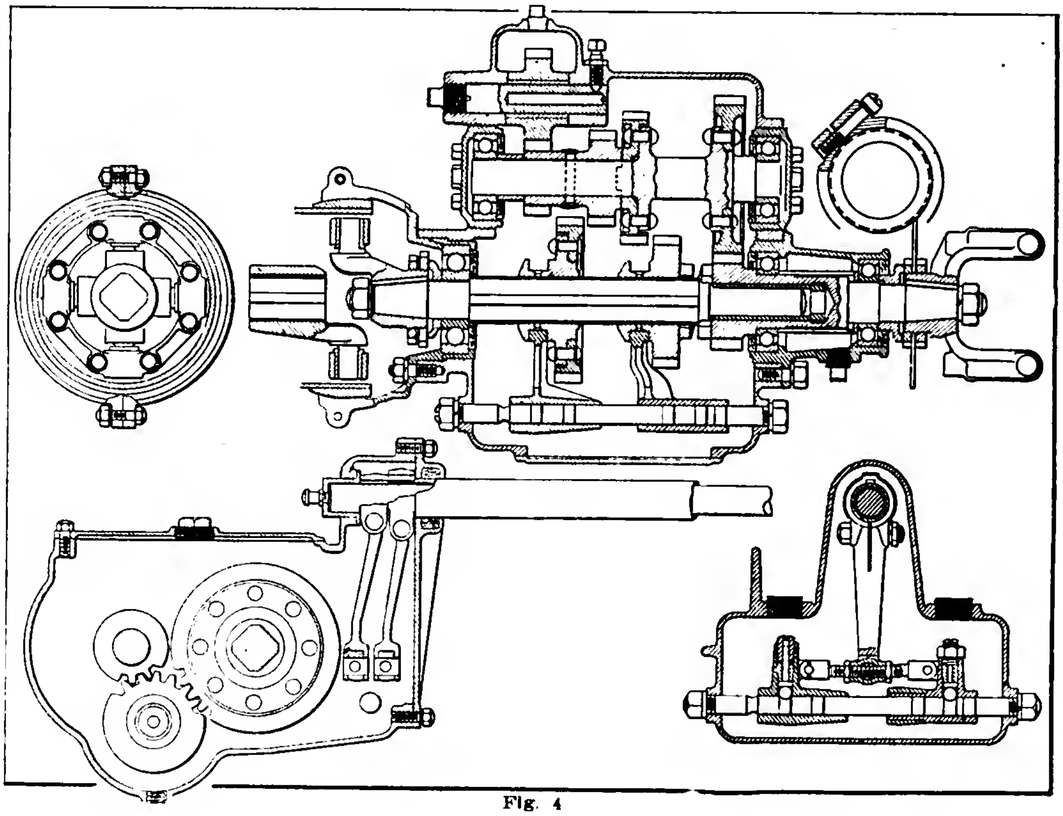

Fig. 4

Rejuvenating the Old Automobile

By J. B. MERCER.

Illustrating a modern fore-door type of body as it would appear on a Cadillac "Thirty" touring car, giving all the information required by a body maker, and showing how the body will appear when made. A means is afforded for clearing the side levers, and the material specifications are given in sufficient details to serve the end.

GENERALLY speaking, the process to be employed in the construction of a new fore-door type of body for the Cadillac "30" touring car is a mere repetition of the process which was laid down in THE AUTOMOBILE of June 16 for the rejuvenation of a Franklin Model H car. Barring the necessary changes in dimensions, and making sure that the new body will present an artistic appearance when completed, there is little else by way of skill which cannot be furnished by a body maker or a reasonably well-equipped repair plant upon demand.

In this case, the panel and moulding effect with the left side door, and the bent wood pillar to form the doorway, are identical with that of the process set down for the Franklin Model H, in which the framing is of wood, and sheet aluminum construction is employed, utilizing steel angle pieces and castings, to a certain extent, to strengthen the framing and brace the structure. In this example, Figs. 6, 7, and 8 show the side, front, and top elevations respectively, and the side levers are bent, as indicated in Fig. 7, so that they both fall outside of the body, whereas in the Franklin Model H the speed lever passed to the inside of the body through a slit. In the Cadillac model it is inexpedient to bend the levers so that they will fall inside of the body, due to the height of the quadrant, and the distance from the quadrant to the chassis frame. This specification calls for a new dash, which should be made to conform to the general finish of the doors and trim of the body throughout.

The pillars making the framing around the door are of bent ash in one piece, extending from the top line of the seat all the way around; fastening is provided for at the curve of the seat, and outer surface is finished so that it is in the plane of the seat panel. To prevent the joints from showing in the finished work the moulding is placed on the seat sufficiently offset to provide a good joint. Below the seat line, the pillar is fitted back onto the under body for a distance, as shown, it being the idea to have the moulding run along the edge of the panel, from the dash to the seat, so that it will come in line with the vertical moulding of the seat.

The pillar forms an offset, measuring from the side of the body, equal to the offset distance of the seat at its point of contact with the same, and, as in the Model H Franklin, the dash in front is brought out to the same line. The fastenings of the pillar to the body are by means of screws which pass through the panel and into the body framing. The new dash should be 3-4 of an inch thick material, which may be of white pine, if the cost is to be kept down, and of Mexican mahogany, if first-rate work is wanted. The lock-post is framed into the pillar at the bottom, and to the side rail at the top; the surfaces of the sides and the doors should be covered with No. 16-gauge aluminum, fastened under the moulding at the top, to the curvature

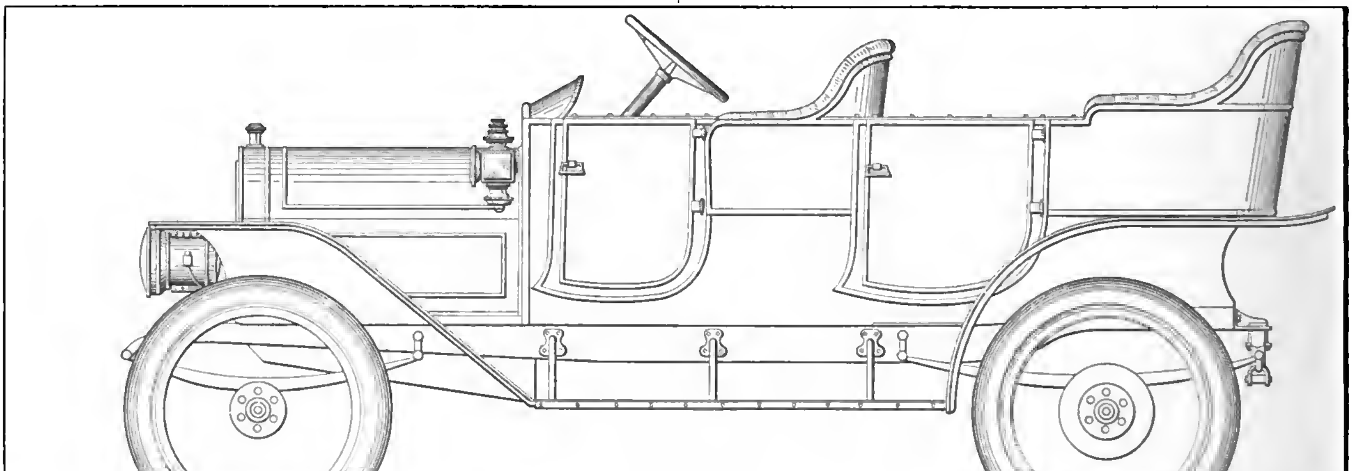

FIG. 5

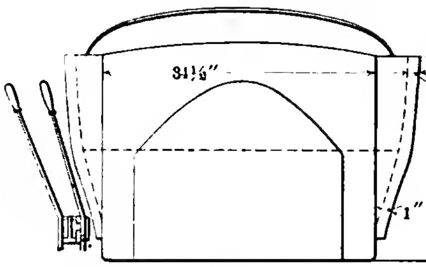

FIG. 7

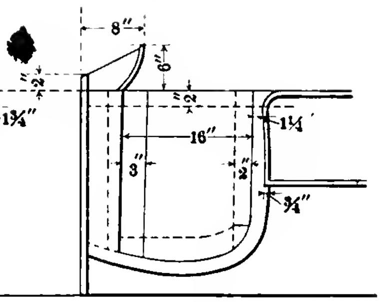

FIG. 6

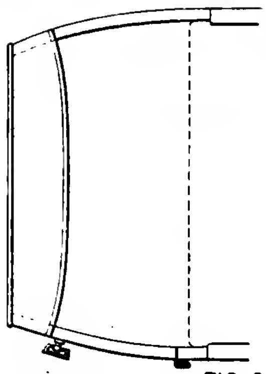

FIG. 8

Fig. 5—Side elevation fore-door type body for Cadillac "Thirty." Fig. 6—Details of fore-doors. Fig. 7—Front View. Fig. 8—Plan

of the dash and to the outer edge of the pillars; it should be turned in around the doorway, and at the joints around the front portion of the side of the seat. The upright curve moulding which gives effect at the pillar should be riveted at the panel. On either side, the framing and the moulding will be symmetrical in this example, because the side levers do not interfere. The door framing is indicated by dotted lines with sufficient dimensioning to govern the work. As a further aid, the body builder may consult Fig. 7, which is a front view, from which the lines, and the one important dimension may be had. The hooded dash, as here given, adds to the general appearance of the body, but this phase of the situation is subject to such change as the taste of the owner would seem to indicate, although care must be exercised not to go too far in a matter of this sort for fear the general harmony will be upset. The lower section fastens to the door top piece, and is so designed as to move outward with it. In the selection of the hinges and lock for the door it is worth while exercising some care, and the body maker is enjoined to use screws of sufficient length to fasten the hinges in secure relation.

Roughstuff Can be Mixed as Well as Purchased

Shop-mixed "roughstuff" for body finishing may be compounded by taking equal parts by weight, of keg lead, oil ground, and any good American filler. The two to be thoroughly reduced to a stiff paste by beating in equal quantities of coach japan and rubbing varnish.

Forced Lubrication—Trend in English Practice

By R. K. MORCOM

(Third Installment)

The pump should be of ample size—Charts are used to indicate the relation of pressure to quantity—Effect of a choking suction is discussed—Types of pumps are given attention—Result of a series of trials on different types of pumps are shown.

GENERALLY, in designing a forced lubrication system, the following points must be kept in mind:

Have a pump of ample size, with good big suction and delivery pipes. There is a tendency to fit pumps and pipes too small to realize the benefits of forced lubrication. The effect of a choked suction is well shown in curve IV (Fig. 14). From the curve of discharge given earlier it will be seen that the discharge from the clearance spaces is quite appreciable, and too small pipes or pump may lead to the ends of the system being starved. A good rule is to make the discharge from the pump at full speed depend upon the total clearance. Thus, with a plunger pump, if the volume swept out per minute on the discharge stroke be V, and the sum of the peripheries of all bearings at each discharge point be P, then $V = 8 \times P$ is a good value.

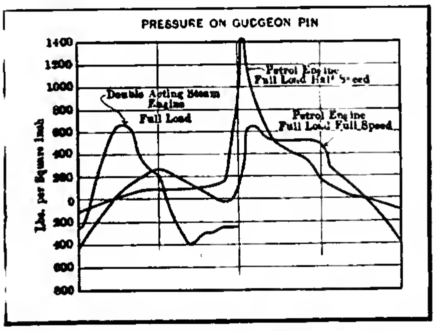

Fig. 10—Chart showing pressure on gudgeon pin and how it varies under different conditions of load and speed

For the main delivery pipe, if B be its bore,

take $B = \dfrac{P}{480}$,

Another point which makes it necessary to have an ample pump is that due to centrifugal and inertia effects on the oil in the moving parts, variations in pressure occur beyond those due to fluid friction and escape at clearances. To indicate the nature of such influences, a series of diagrams were taken with an ordinary indicator coupled direct to the main bearing, and through a flexible connection to the top end. The curves traced are given in Fig. 13.

Oil pumps of various types are used, the most common being:

(1) Plunger pump.
(2) Gear pump.
(3) Vane pump.

The first is the most positive, and probably the most generally efficient. The second is good, and lends itself to simplicity of design. The third does not appear to be any good for high pressure. Centrifugal pumps are generally unsuitable, especially with thick oil. A series of trials run on different types of pumps are recorded in the curves of Figs. 14 to 19. It will be seen that the horsepower unit is quite small, so that the question of drive is an easy one.

The filter which must be fitted in the system should be efficient and accessible. It would be an advantage to place it in such a position that by lifting a cover it could be at once got at and periodically changed. The spare filter could then be cleaned ready for the next change-over. The filter should have ample area, as the suction pump must be quite free. A good design of filter is shown in Fig. 20, but, of course, to suit special space requirements the design is subject to great modification. A point to be remembered which is often overlooked is that perforated zinc and copper are not good neighbors in an oil well where water may be present. The oil pipes and oil ways should be ample in area, free from sharp bends and corners, and of adequate strength to stand the highest pressures that may fall upon them. Steel pipes made to template are better than copper pipes, since the latter have been found to develop mysterious fractures. Where it is possible, hollow shafts and rods should be used to facilitate the distribution. All oil pipes should be

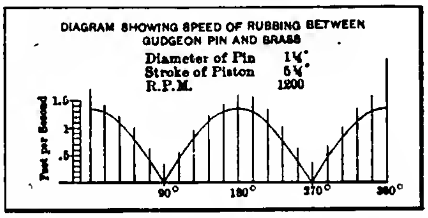

Fig. 12—Diagram showing speed of rubbing between gudgeon pins and brasses under fixed conditions as stated

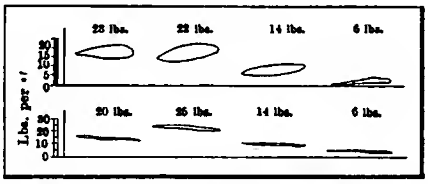

Fig. 13—Method of depicting the pressure in pounds per square inch for given pressures

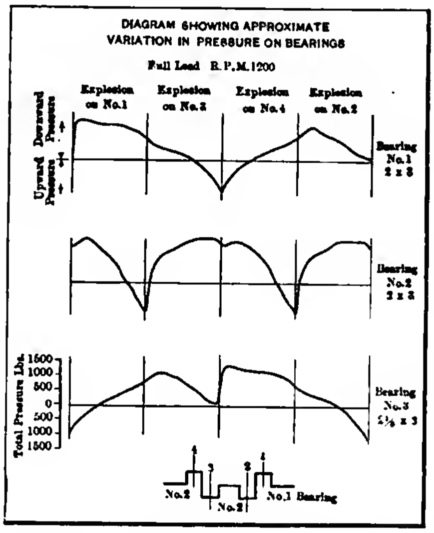

Fig. 11—Diagram showing pressure variations on bearings, also giving total pressures

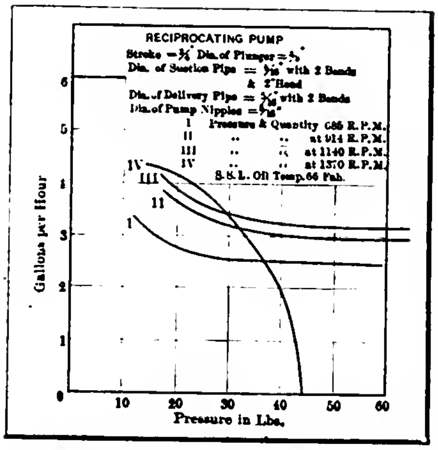

Fig. 14—Showing the capacity of a reciprocating pump under different pressures in pounds per square inch

carried in positions where they will not get in the way of overhauling, and will be protected from risk of damage. It is a good thing to bring the pipes up on the under side of the bearings in motor car engines, since they can be carried close to the cross-frames which usually support the bearings. In fact, the oil ways may actually be drilled in the crankcase casting. The edges of oil holes in parts subject to stress should be carefully rounded, or they may be origins of surface cracks leading to ultimate fracture.

In testing the pumps some trials (see pump trial curves) were taken on heavy oils to show the effect of congelation in cold weather. Owing to the small quantity which can pass, a heavy pressure may come on the delivery pipe and gauge, if fitted. This is one reason for fitting to relieve the pressure. A bye-pass valve alongside the gauge opening into the make-up oil tank was used with success in one instance. The best place for an automatic relief valve is on the delivery pipe close to the pump. Such valves are, however, a source of trouble, and should be avoided; as a rule, a gauge can be obtained to stand far greater pressure than will be put upon it in this way, and still be sensitive at the normal pressure.

A very short time is required to warm up the oil, and the trouble from this source is probably less with forced lubrication than with any other system.

The chief wear in the bearings on a high-speed engine occurs at starting and stopping. A pump very quickly forces oil into a bearing, probably more quickly than the oil will get there in any other systems. A non-return valve on the delivery pipe is possibly of value to ensure the system remaining full. The chief argument in favor of a pressure reservoir supplying oil is based on the need for oil at starting, and such a fitting for the pump to discharge into might be of value.

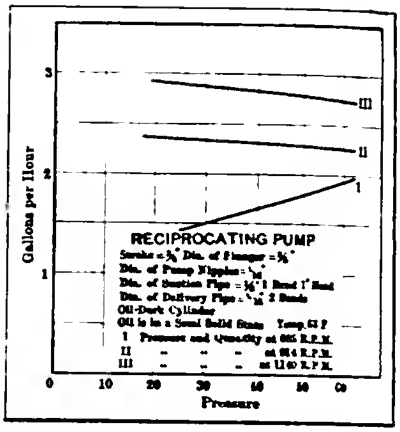

Fig. 15—Capacity of a reciprocating pump of the plunger type with oil in a semi-solid state

Any system in which a charge of oil is used for long periods may suffer from contamination of the oil. An experiment was made on a car fitted with forced lubrication. The sump was filled with a pure mineral oil called "SL," following the viscosity curve given in Fig. 21, and the car run for 3,000 miles in about four months on and off.

Meat from Foreign Exchanges—Cut to the Bone

Digest Along Technical Lines for the Engineer

Which to choose, the soft or the nervous motor, the normal or the pushed motor, is a question now demanding an answer. A similar question was mooted among horsemen. Could thoroughbred stock be used for common work or only for a few star performances each year, to be coddled all the rest of the time? The Americans have obtained excellent work from the refined stock by nourishing it well and giving it suitable care. The problem with regard to automobiles is: Between two motors, one giving 30 horsepower, with 110 mm. bore and 120 mm. stroke, and another giving exactly the same brake horsepower with 85 mm. bore and 160 mm. stroke, which should the purchaser choose?

An examination of the thermic and the mechanical efficiency in both cases will throw light on the question. The motor deriving a given power from the smallest amount of fuel is, of course, most efficient, and the question becomes, therefore, whether the means employed for reaching the higher efficiency are prejudicial to durability or other desirable properties of a motor, or perhaps are harmful under some conditions and not under others. From what is known of motors it is admitted that the utilization of fuel is more perfect in proportion as (1) the temperature of the cylinders is higher, (2) the piston speed is higher and (3) the initial compression is higher. But there is a limit to the possible temperature of cylinders. Lubricating oil decomposes at about 250 deg. C. The inner cylinder walls must be below this heat. In a water-cooled motor the outer walls must be below the boiling point of water, which is 100 deg. C. Other things equal, the air-cooled motor should give a better thermic efficiency than one cooled by water, since fewer calories are lost if the outer walls may be maintained at an external temperature of 200 deg. instead of 100, and, in accordance herewith, all fuel economy tests in the past six years have been won with air-cooled motors. (The author does not seem to consider that, with continued operation of the motor, as many calories may be lost to maintain 200 deg. as 100. The question is hardly one of temperature, but of how many calories must be carried away in order to maintain operating conditions, and this should lead to cooling of the piston rather than of the external portions of the cylinder walls, which play no other part than as conductors of the heat from the inner walls. Some cooling of the piston is actually effected by copious lubrication, and this may account for the winning of fuel economy tests by air-cooled motors. To keep a temperature of 200 deg. from rising further should in reality require the accession of more calories than to keep 100 deg. from rising further, considering that the outside temperature is nearer to 100 than to 200, and will carry away more calories from the hot than from the relatively cool surface.)

The quantities of heat transmitted through a wall of which one surface is at a higher temperature than the other are proportional to the extent of the surface through which the transmission takes place. If 100 calories pass through 1 square centimeter of wall in one minute, 200 will pass through 2 square centimeters in the same time. In a motor, therefore, one should choose the combustion chamber which has the smallest surface with the largest volume. As a spherical form is excluded, this leads to the hemispherical combustion chamber used in many modern motors, or to the system which causes the combustion chamber to remain of the same volume and wall surface during the entire stroke of the piston, by having two opposite pistons always moving in the same direction, as in the Gobron system and some horizontal two-cylinder motors with the two pistons working upon the same crank.

The logical consequence of a hemispherical combustion chamber is the location of valves in the top of the cylinder head, opening directly into the cylinder. The pushed or nervous motor is of this type, while the normal motor has the valves located in little lateral extensions of the cylinder, with plenty of wall space.

Here is a distinct thermic gain in the nervous motor over the normal one, without any loss in robustness or reliability.

With regard to piston speed, or rapid expansion of the gases during the power stroke, it is understood that the loss of calories through the walls is so much greater as the time is longer during which the heat is transmitted. If 100 calories pass in one minute, 200 will pass in two minutes. (This proportionality is scarcely established, nor well founded.) The time during which the hot gases are in contact with the walls should, therefore, be diminished. This is done by piston speed. On the other hand, when the exhaust gas is expelled it is still hot and carries with it many calories which it would have been better to have utilized. To reduce the number of calories lost in this manner the stroke should be lengthened. Here is an apparent contradiction. But, by doubling the speed of the stroke, one-half of the calories which would be lost by lower speed are saved and made available for expansion, which is useful work, and by doubling the stroke at least one-half of the calories so gained are turned into work, although the other half may escape through the added wall space. The net gain is realized in the nervous motor with 85 mm. bore and 160 mm. stroke which has a linear speed of 8 metres per second at 1,500 revolutions per minute. The normal motor, which also runs at 1,500 revolutions per minute, has a linear speed of only 6 metres. But in the first case the piston of 85 mm. diameter weighs less than the piston of 110 mm. diameter; the moving pieces are lighter, and, at the same r. p. m. it is seen that the pushed or nervous motor is less affected by the disastrous inertia of the masses. At this point there should be superiority in durability over the normal motor.

Let us pass to the third thermic factor, the compression. Our nervous motor of 85 by 160 is supposed to have a cold compression of 5.7 kilograms, based on the proportion of total cylinder to compression chamber volume, while the normal motor, 110 by 120, has only 3.5 kilograms initial compression. With these figures experience shows that the thermic efficiency of the two motors is as 36 to 24; that is, that the low-compression motor, for a given amount of work, will consume 36 litres of gasoline, if the other consumes 24. While the saving of one-third of the gasoline consumption, by using the nervous motor, is an advantage, it goes without saying that the mechanism of the high-compression motor is subjected to high stresses and that these must be taken into account in the manufacture and must result in a considerably higher cost of production. Besides, there are materials in all motors which have not the great strength of fine steels. The bushings of piston and wrist pins will be worn down so much quicker as the pressures are higher for the unit of areas. The pushed motor will begin to "knock" quicker than the soft motor. This is bad, but the saving in gasoline will easily pay for new bushings, as often as may be required. On the whole, with regard to thermic efficiency the superiority of the nervous motor seems to be established without serious drawbacks.

Among the means for improving the mechanical efficiency good lubrication comes first, and it must be admitted that this requirement is satisfied as fully in the soft as in the nervous motor. (The author should perhaps admit a little more.) The lateral pressures of the piston against the cylinder wall may be reduced in the nervous motor either by using a connecting rod long in proportion to the crank throw or by having recourse to offset. Our 85 by 160 is an offset motor, while our normal motor is symmetric. The substantial advantages of the offset have been demonstrated, and while the public is still a little wary of this improvement, its mechanical value to increase efficiency is undeniable, and several manufacturers employ some offset without saying anything about it to their clients. The features referred to produce a somewhat high motor, but this is scarcely an inconvenience, except in so far as it also results in a high price. The nervous, long-stroke, high-compression motor is mounted on ball bearings, while the normal motor still contents itself with smooth crankshaft bearings. At this point the public came near causing a fatal reaction, but fortunately experience has finally shown that the prejudice caused by a few errors in dimensions and design was groundless, and the leading houses now employ ball bearings on the crankshaft without misgivings, and their independence of regularity of lubrication constitutes another advantage of the pushed over the soft motor, from the average motorist's standpoint.

In this rapid survey of the situation a few points have been passed in silence, such as the increased pleasure in using the nervous motor and the great flexibility of its power. But, now, there is the driver, the caretaker. It is so pleasant to have a responsive motor that the accelerator remains unused. On the other hand, too many of the nervous motors are not provided with an advance of ignition, although this provision is really indispensable for them, and few drivers understand how to change speed at the proper moment. And the pushed motor demands not only expert driving but also competent care.

In conclusion it may be said that all those who love their vehicle and are willing to give it the care which every high-strung mechanical organism, as well as every animal organism, requires, may safely choose the pushed and nervous motor, particularly if they drive the car themselves. But those who must trust the vehicle to strangers and do not pose over a chauffeur who likes his work, had better be content with the soft motor of the less advanced type.—C. Faroux in *La Vie Automobile,* May 14.

Speaking about Lepape's experiments with two-cycle motors, F. Garlès gives an abbreviated account of the failures which were met and overcome. Lepape had first tried to replace the ordinary compression pump by two pumps, one for air, of a volume larger than that of the motor cylinder, and another for introducing a rich gas taken from a special carbureter. At each turn the pump introduced in the cylinder a larger volume of air than was necessary for filling it, so as to produce complete expulsion of gases, and then the little pump injected the rich mixture. The result was phenomena of condensation interfering with operation. Then he thought of using a small pump for injecting the liquid gasoline together with a jet of compressed air, also without success. The direct gasoline injection pump was also quickly abandoned. Then came the Giffard injection. A motor based on this principle gave a regular operation, but much too high consumption of fuel. The system of introducing the fresh gas by means of the suction produced in the cylinder automatically by the rushing out of the burnt gases was then tried. "This motor," says Lepape, "worked with extreme regularity but without giving much power. Then I varied the volumes of dead space between the suction pump and the motor, so as not to get too strong a vacuum, which aspired the fresh gas unnecessarily fast. It proved very difficult to find the exact volumes of dead space which should exist above the pump to correspond with the maximum speed and which would also work well with low speed."

With regard to the two-cycle motor's inclination to overheat, Lepape says: "I have been struck with the contrary experience with motorcycles, an experience often repeated. Two motorcycle motors of the same power, but one two-cycle and the other four-cycle, are set going without load at the same time, and the two-cycle motor will always run longer without overheating than the other, usually three times longer." Lepape explains this by the action of the bottom ports for exhaust in the two-cycle motor as compared with the jamming of exhaust gases in the top of the cylinder during their expulsion in four-cycle motors. Explaining the mechanical superiority of two-cycle motors, Lepape points to the waste occurring in four-cycle motors, because induction and expulsion and compression must be done with piston rings whose tension and friction with the cylinder walls are determined by the requirements for the power stroke. "The mechanical work absorbed by the frictions is therefore much greater in the four-cycle than in the two-cycle motor," concludes Lepape.—*La Technique Automobile et Aérienne.*

Questions That Arise—General in Scope

Completion of questions in relation to electrolyte for batteries——Principle employed in the removal of carbon from motor cylinders——Discussion of the dangers involved——Danger involved in making experiments——Precautions to take——Curves showing the pressure which will be generated in a cylinder, first by gasoline, and second by gunpowder——Gunpowder may be used to start motors——It is too much of a hazard for the average autoist——Requires special mechanism.

[110]—Granting that nitrates will behave to the greatest detriment of the battery, and assuming that it is of grave importance to eliminate such "forming solutions," how should the test be made?

Procure a test tube and proceed as follows:

(a) Place 25 grams of the electrolyte from the battery in the bottom of the test tube;

(b) Add 10 grams of solution of proto-sulphate of iron;

(c) With great care, add 10 grams of (chemically pure) concentrated sulphuric acid.

If there is nitric acid present, a brown stratum will appear between the electrolyte and the concentrated sulphuric acid. This test may fail if the presence of nitrate is as a mere trace.

MORE PRECISE TEST MAY BE MADE AS FOLLOWS

Procure a nitrate test tube as illustrated last week and then proceed as follows:

(a) Place chemically pure copper filings in the bottom of the tube at *a*:

(b) Place a few drops of proto-sulphate of iron solution in the neck of the bent tube *b*:

(c) Apply heat (gently at first) by means of an alcohol flame, at the point *a*;

(d) The test will fail if much chlorine is present.

In the absence of enough chlorine to defeat this test, provided nitrate is present, the color of the electrolyte will change to a blackish brown.

Suspecting the presence of chlorine, the process must be extended; add a small amount of gold leaf, and somewhat more of (chemically pure) concentrated hydrochloric acid to the electrolyte; boil. If nitrate is present in the electrolyte, some of the gold will dissolve.

If any of the gold dissolves, it will be denoted when a few drops of proto-chloride of tin is added; the color will develop the purple Cassius. This test is very delicate, and will develop the merest trace of nitrate in the electrolyte.

[111]—How may one determine the effect of temperature on the specific gravity of sulphuric acid electrolyte?

The tabulation as here offered will be a sufficient aid for the purpose.

[112]—Where can the reagents specified for use in testing for impurities in storage batteries be procured?

Any chemist will furnish them.

[113]—What is the principle of the removal of carbon from the combustion chambers of the cylinders of motors?

Carbon, which is the main element of the crust which forms, may be removed if it is combined with oxygen to form a gas as CO or CO_2. This may be accomplished by introducing some oxygen compound into the cylinders, which will, in the presence of the heat of combustion, disintegrate, and in the process of separating into its elements, free the oxygen and induce the formation of a gas, utilizing the carbon of the crust in the new organization. There are two oxides of lead which have this property. Lead oxide (PbO), and litharge or red lead (Pb_3O_4), the latter being the most efficacious for the purpose, simply because there is more oxygen in it. What happens is this: There is a sufficiently high temperature to melt lead, and the oxygen at the instant it is unlocked from its bond with the lead by the heat combines with the free carbon which is present in the crust, forming CO or CO_2. The new combinations are in gas form; CO represents carbon monoxide, and CO_2 is carbon dioxide. The residuum is metallic lead; it will either be heated sufficiently to vaporize and will pass out through the exhaust port in this form, or it will remain as molten metallic lead: the chances are that it will be driven off as a gas.

Manganese dioxide is another of the oxidizing agents that is relied upon to flux with. The formula for this compound is MnO_2; it is black in color, opaque, and a good conductor of electricity. When heated alone it is infusible, but gives off oxygen, forming Mn_2O_3 or Mn_3O_4 depending upon the intensity of the heat. In the presence of carbon the manganese dioxide is changed to MnO (manganese monoxide), and the carbon takes up the oxygen, forming carbon monoxide, or carbonic acid.

The exact composition of the decarbonizers which are used in motor cylinders, as furnished by the various compounders, has not been published: they may belong to the class as above, or they may be of that class of chemicals, as kerosene oil, which merely creeps in behind the crust, and detaches it from the walls of the cylinders. This latter principle is employed in connection with steam boilers for the purpose of loosening the scale, and it is given preference by some engineers on account of its ability to destroy the bond of the scale to the steel, without inducing oxidation.

It has been found that the so-called carbon formation in motor cylinders is a combination of carbon and silicon; the silicon comes in through the carbureter, and represents quite a large proportion of the whole crust. The silicon retards the action of the oxidizers which are capable of taking up the carbon to form compounds, for the reason that the carbon is shielded by the silicon.

Just how the silicon can be removed is a matter which will have to be struggled with; when the carbon is floated away as a gas, the silicon will remain, and it may be that a certain proportion of it will float out: it is not heavy in its "dust-like" state, as it is sucked into the cylinders through the intake: the one trouble lies in the paste-like mass it falls into as it mixes with the lubricating oil which is being continually injected into the cylinders.

Lead oxide has one facility from the point of view of silicon; a double silicate is formed if the heat is high enough, and the infusible character of the original silicon is thus reduced to a fusible formation, in which state it may more readily depart from the cylinders.

[114]—The question is frequently asked, Will the carbon remover (as it is called in the trade) attack the walls of the cylinders?

This is a question which thwarts answering when the composition of the carbon remover is unknown.

the composition of cylinder iron?

ın of cast gray iron, as it obtains in certain may be taken to be about as follows:

ITION OF CAST-IRON CYLINDERS

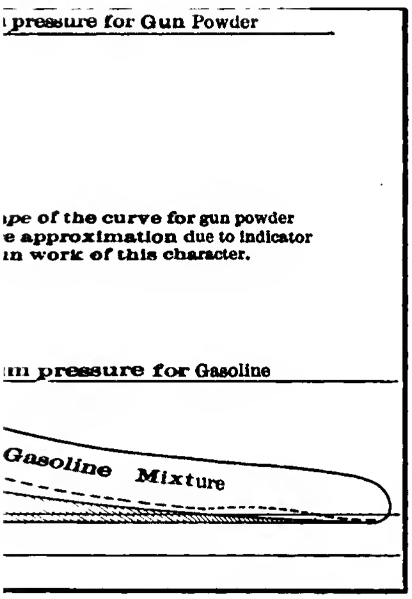
r attached to the process?

er safe to experiment with unknown

ible sources of danger?



-istic Difference Between Pressures and Mixtures of Gasoline

(a) Explosives; (b) Inflammable; (c) Poisonous fumes.

[125]—What is to be done to avoid these dangers?

(a) Let an experienced chemist conduct the test; (b) heat a grain (a very minute part) of the carbon remover, under conditions of suitable protection, and note if it explodes; (c) take a second minute division, place it on an anvil, strike it a sharp blow and note if it detonates; (d) heat the anvil, then repeat the experiment, and note if detonation will follow a blow when the compound is heated; (e) in order to observe if the compound will burn, take a spark-plug out of one of the cylinders of the motor, place it in the solution in such a way as to get the benefit of a spark; complete the high-tension connections just as when the spark-plug is working in a cylinder; crank the motor, and when the spark is generated at the plug which is placed in the solution, if it is inflammable it will be readily noted. The spark should take place just at the surface of the solution so that atmosphere will be free to sweep over the surface and provide oxygen to complete the set of conditions which underlie success in the process of making a fire, i.e., fuel, oxygen, and a flame.

[126]—Will these experiments, if they show nothing, be all that is necessary to prove the absence of danger to the experimenter?

Not necessarily; besides avoiding the inhalation of fumes, there are always the precautions which must be taken when an experimenter is dealing with a series of unknown quantities.

[127]—Is there any reason for believing that there is a hazard of moment involved in this experiment?

No. It might even be pointed out that there is practically no chance of getting into trouble; this is no reason for going about it in such a way as to have to bear the brunt of an explosion if one is induced. All research work is dangerous—it is a case of dealing with unknown quantities.

[128]—Is it not possible to start a motor by means of gunpowder?

Yes. This method was employed in "Raymond" engines, as manufactured for stationary work about fifteen years ago.

[129]—How was it managed?

(a) Black blasting powder (BB DuPont) was loaded into a cartridge; (b) the cartridge was placed in a breech-block in the combustion chamber of one of the cylinders, and when the piston was over the dwell point, on the down stroke, a firing pin so placed as to dent the cap was struck a sharp blow. The powder thus ignited performed the function that is ordinarily performed when gasoline mixture is compressed and ignited.

[130]—What is the matter with this idea?

Nothing. The cylinder of the motor which is fitted with the breach-block, in which the powder is placed, is to all intents and purposes the equivalent of a cannon. The only question is, should cannons be made of cast iron; unless it is proper to add that cannoneers are supposed to have great skill and some bravery.

[131]—How did the idea work in the instance cited?

Very well; there was only one casualty; it was due to the use of an excess of "smokeless" powder. The cylinder walls of the Raymond engine were about 1 inch thick; in automobile motors the walls are rarely ever more than 5-16 of an inch thick.

[132]—What is the reason why danger is courted when gun powder is substituted for gasoline mixture?

Gasoline mixture is relatively slow burning, and the piston is capable of receding swiftly enough to prevent the formation of a high-pressure wave. The two curves, as here given, will tell the tale better than words. As the curve depicts, the maximum pressure for mixtures of gasoline is nearly 200 pounds per square inch. In the case of gunpowder it is given as 600 pounds per square inch. In a motor of the automobile type, during some experiments which were conducted a few years ago, it was found that the pressure due to the use of gunpowder was frequently very much higher than that as here given. The point to be made here, however, is that the piston cannot accelerate at a sufficient rate to run away from gunpowder pressure fast enough to prevent the pressure from piling up at the terrific rate which spells hazard.

Showing Connections of 4-Cylinder Coil

Editor THE AUTOMOBILE:

[2,301]—I have an automobile which is fitted with a magneto ignition system, and a single coil auxiliary. Please show the connections, if a 4-coil auxiliary system is used, with the understanding that separate spark plugs will be employed.

Kingston, N. Y. SUBSCRIBER.

Fig. 1 shows the arrangement of the 4-unit coil, storage battery, timer, and spark plugs. It is so arranged and marked that by following out the connections no further information will be required.

Carbureter Adjustment Is Unruly

Editor THE AUTOMOBILE:

[2,302]—I have a carbureter on my ——— car, which has a knurled disc on the end of the needle valve, and a lock spring as shown. The carbureter gives trouble, although it works all right for a time after I make an adjustment of the needle valve. I do not understand, however, why the adjustment does not remain permanent. Is the trouble due to temperature changes?

Newburgh, N. Y. READER.

It is a great mistake for an autoist to jump to an impossible conclusion when the performance of a carbureter is improper. In this case there is no temperature question involved, such as will give serious trouble. The real difficulty lies in the lack of permanence of the locking method, and the needle valve adjustment is disturbed. The remedy will lie in the direction of a proper fit of the needle valve stem where it threads into the casting, and a security lock. If the spring does not hold, replace it with one that will (see Fig. 2).

Overhanging Lug Source of Trouble

Editor THE AUTOMOBILE:

[2,303]—I enclose a sketch for your information, which shows that the exhaust pipe is held in place by two studs, one of which screws into a lug which extends down from the underside of the exhaust chamber. The lug broke off. Is there any way by which I can have it fixed?

Wilmington, Del. K. A. C.

It will be extremely difficult to do anything with this sort of a break. The extension lug is bad designing. Autogenous welding, however good it may be in general, cannot make the lug any stronger than it was in the first place, and it proved to be below the requirement. One way perhaps, would be to have the lug autogenously welded, and then put a 3-16 inch plate over the whole face, and the manifold up against the plate. In this way the 3-16 inch plate will furnish the strength necessary, and it will be held in place, to some extent by the lower stud, but in the main by the upper stud. Asbestos packing may be put on both sides of the plate to make a tight joint.

Spark Plugs Have to Be Tested Occasionally

Editor THE AUTOMOBILE:

[2,304]—In my motor, the spark plugs seem to soot up too soon, considering the performance which is obtained in other types of motors, and the space is so cramped that it is a good deal of trouble to take out the spark plugs and find a place to lay them down without undoing the connections, for the purpose of observing if the spark is good. In the first place, I would like to know why I have this trouble, and I would also be glad to have any suggestion you can offer which will make the work more agreeable.

Baltimore, Md. C. S.

The sooting up of the spark plugs may be due to a variety of causes, prominent among which are (a) an excess of lubricating oil; (b) lubricating oil which is not suitably built for cylinder work; it may have too much free carbon, or the flash point may be too low (if it is mineral oil); if it is not mineral oil it should not be used for this character of service, although certain forms of vegetable oil have been used with success, notable among which castor-oil may be mentioned; (c) too much gasoline; (d) spark plugs in the wrong place; they work best on the intake side.

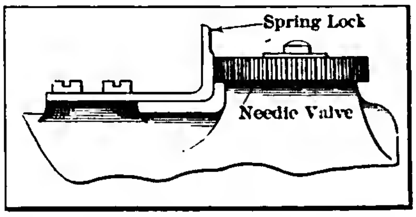


Fig. 2—A troublesome lock for a needle valve on a carbureter

Fig. 4 shows a scheme which helps considerably when it is necessary to remove the spark plugs from the cylinders and test them out. The spark plug A may be screwed out of the cylinder and then inverted, after which it is placed in a slot in the end of the bent flat iron member marked B. It is a convenient arrangement which any autoist can make for himself.

Number of Cars in Use in United States

Editor THE AUTOMOBILE:

[2,305]—Can you inform me as to the total number, and approximate value of the cars in use in the United States; also the value of the cars in use in the United States; also the value of the 1910 output.

Warren, Ohio. TRUMAN GRISWOLD.

Including foreign makes of automobiles, and discounting for the cars which are out of commission for various reasons, it is believed that the balance of automobiles in actual use will approximate 310,000, counting up to the 1910 output. What these automobiles cost originally is a matter which will scarcely be worth considering, but their present value, on a taxation basis, might be fixed at $620,000,000.

The 1910 output has been conservatively estimated at from 200,000 to a maximum of 280,000 automobiles, and the work involved in their construction, including all of the items which might well be considered, represents the comfortable sum of $485,000,000, an estimate which is believed to be conservative by those conversant with the situation.

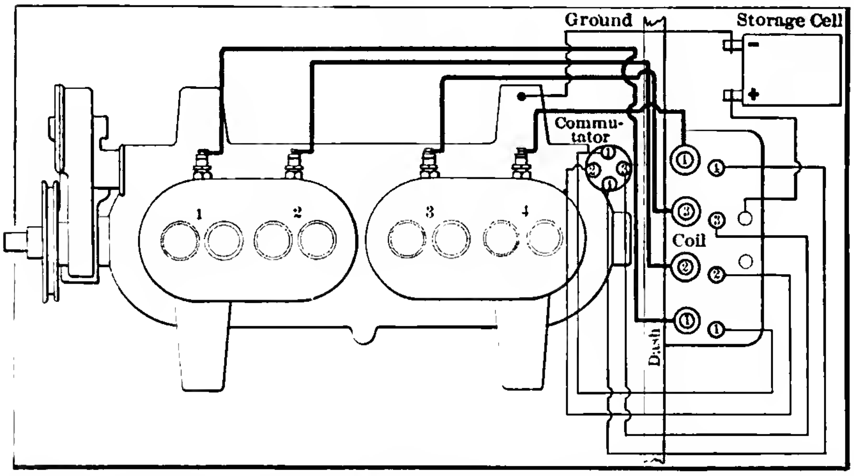

Fig. 1—Diagram of connections of a four-coil ignition system to spark plugs from a storage battery

All About Spark Coils for Ignition Work

Editor THE AUTOMOBILE:

[2,306]—1.—Please explain briefly the construction of a spark coil as used with battery ignition, giving the sizes of wire, and the amount of each.

2—What is the nature of the change of the current after leaving the coil, or that in the secondary winding?

3—What is the difference between direct and alternating current?

4—Explain what is meant by "selective-type transmission."

Erie, Pa. WILLIAM O. YATES.

1. Each unit of the spark coil is made up of an iron core, which is composed of a bundle of soft iron wire, about 3-4 of an inch in diameter, and about 6 inches long, over which an insulating spool is placed, upon which spool are wound first a primary coil, composed of about 1-2 pound of No. 36 double cotton insulated copper wire, and second the secondary winding of about 1-2 pound of No. 18 double cotton insulated wire. It is necessary to insulate the primary from the secondary with great care, using oiled silk or paper, overlapped at the joints.

2. The secondary current will be a modified prototype of the primary current; if an alternating current is impressed upon the primary windings, a somewhat modified form of the same wave will be induced in the secondary windings. If the primary current is periodic and pulsating the secondary current will he periodic and pulsating also. If a direct current is used an interrupter must be employed, otherwise the step-up transformer, which is what it amounts to, will fail to work. There must be a variation in the primary in order to produce induction in the secondary winding of the same coil to get the result.

3. The difference between a direct and alternating current is indicated by the language. A direct current is one which flows in one direction only. An alternating current is one which flows alternately in opposite directions.

4. A selective - type transmission is one which is so contrived that the operator may select at will the gear into which he wishes to engage, without having to engage the respective gears from low to high progressively, or from high to low progressively.

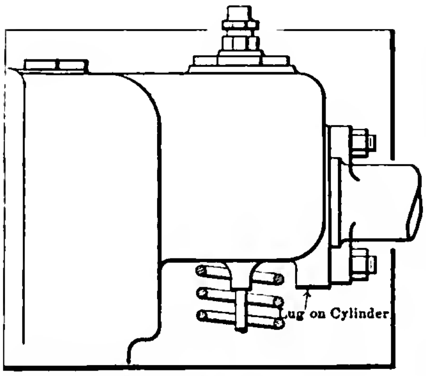

Fig. 3—An over-hang lug on a cylinder that is likely to break off any time

Merely Looking for Automatic Carburetion

Editor THE AUTOMOBILE:

[2,307]—On account of a difference of opinion between various automobile users, I wish you would answer the following questions through your inquiry columns:

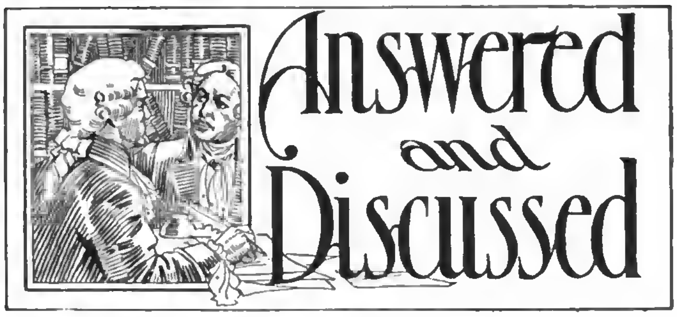
1.—Has it been your experience, or in your opinion is it possible, for an internal combustion gasoline motor to be so built that spark and throttle can be rapidly advanced with the machine under load and still not cause either a spark or gasoline knock?

2.—Is it possible to get a carbureter which, when adjusted for normal temperature, will work equally or nearly as good without adjustment on a cool or damp day?

St. Bernard, Ohio. LESTER E. KEMPER.

1. Sudden changes of the character or quantity of mixture when a motor is laboring should cause trouble. Shock is a bad condition to induce in anything. A motor is no exception to the rule.

2. A properly contrived carbureter will compensate within reasonable limits under all likely conditions of temperature change; the auxiliary air is usually heated before it enters the carbureter so that weather questions are more or less eliminated. The fact remains that the viscosity of gasoline changes considerably with temperature.



Trouble Will Come Soon Enough

Editor THE AUTOMOBILE:

[2,308]—I have had several arguments with friends as to the advisability of using ground cork in a selective transmission, also as to the use of Dixon's graphite and cedar sawdust mixture. I rather favored the idea that either ingredient would have a tendency to keep lubrication away from either the roller or ball bearings. Am I correct in this supposition? What do you advise where first and second speeds are not so quiet as one might wish?

Romney, Ind. C. L. B.

If the transmission gear is not properly made, and it emits a tuneless grind, no amount of sawdust will eliminate the prime difficulty. This cruel treatment would probably destroy a good transmission gear. Perhaps the noise can be reduced to a tolerable level by copious applications of beeswax, which will have to be applied to the teeth of the gears after they are warmed up sufficiently to melt the beeswax. Beyond this, a proper amount of suitable transmission gear grease should be used. The transmission gear grease may carry the right proportion of Dixon's graphite, which is regarded as an efficacious luhricant. The treatment here recommended will not interfere with the lubrication of the ball bearings. It is useless to recommend that you use one of the available gear ratios; the road condition will settle this phase of the problem automatically. Fix the automobile up so that any one of the gear ratios may be used when the road condition demands, otherwise the automobile will have all the minus virtues of a sore thumh.

Air-Cooled Motor Starts on the Spark

Editor THE AUTOMOBILE:

[2,309]—I have started a 4-cylinder air-cooled motor on compression after removing plugs and cleaning them, which was said to be impossible in your "Letters Interesting, Answered and Discussed." Please let me know why this is impossible.

New York City. SUBSCRIBER.

This question was very completely answered in THE AUTOMOBILE of June 2, under the caption "How About Starting on the Spark," beginning on page 998.

In the meantime it might be well to add that starting on the spark, when the conditions are such as to make it possible, is no very great sign of unusual quality; it is one of the things to be expected of a motor with enough cylinders, provided the gasoline is heated up to its boiling point. In other words this is largely a problem in connection with the gasoline, and to a very slight extent with the motor.

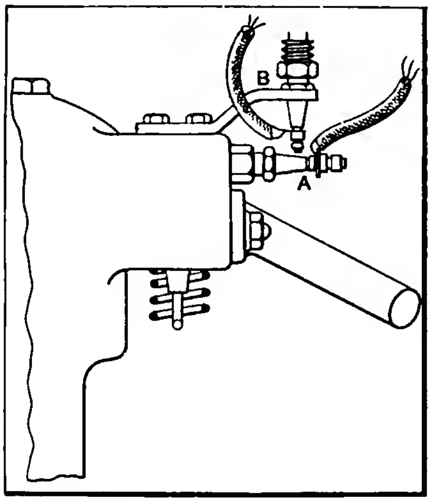


Fig. 4—A means for facilitating the testing of spark plugs, especially when room is at a premium

Studies in Aviation Theory and Practice

By MARIUS G. KRARUP.

THE machine will stop advancing in the new upward direction and it will fall, unless it is self-righting; that is, unless the wind, in tilting the machine upward, has stored a power of gravitation which, in conjunction with the arrangement of the air resistance to movements of its areas, will bring it back to a horizontal position.

If the machine is tipped too far laterally at the same time as upward, the ability to return to equilibrium by operation of rudder planes of any kind, is still further reduced. Reserve power in the motor, to be turned on at such moments, would, however, be very helpful, but would tax the aviator's art or presence of mind.

If the motor becomes stalled at the same time, as is more likely to happen during a disturbance of the balance than when the machine is on an even keel (carbureters in which the gasoline might swash away from the needle valve would seem to be dangerous in this respect), and the machine takes a position in which gravity will not operate it safely, there is no art which will restore the equilibrium by means of rudders. This property must be in the machine itself. In other words, either control by rudder action must be supplemented by some form of control by power (both gravitation and speed are, of course, power elements) which, unlike the ordinary speed of the machine, is independent of the normal but not assured coincidence of direction of propulsion with direction of motion, or, the two available factors, gravitation and the shape and distribution of areas, must be enlisted by the designer of the aeroplane to establish a progressive resistance against the disturbance of equilibrium. Such progressive resistance compounded from the two factors mentioned, as will be readily understood, is the essence in the property of self-righting for a heavy body in air, though the same property is more simply constituted in the case of the lifeboat. By calling both these means into requisition, one for forcibly restoring equilibrium under conditions when the customary rudders become useless, and the other for maintaining it, some independence of weather would seem to be in prospect. And both these means seem to be available in the aeroplane without departing far from its type. A discussion of them should constitute a study in equilibrium.

Arrived at this milestone in the analysis of equilibrium, one finds the subject split into two divisions, equilibrium by control action, which should be reduced to its simplest and least perplexing form, so that the art of aviation shall not depend too much upon exceptional personal traits or qualities in the aviator, and inherent equilibrium or stability, which must be built into the machine, must be the basis for control action, but must not be so pronounced as to interfere with the range of this control action or with quick results from control action within the desirable range of the latter. It must permit considerable deviation from the normal horizontal poise of the structure without offering great resistance, but the resistance must be progressive.

If either control or stability depends upon speed, it is not well secured, as motors may be stalled and wind may interfere with direction, which is a vital element in speed, and may also interfere with that advance movement with relation to the surrounding atmosphere which is the other vital element in speed, as this term is understood in connection with this subject.

In aeroplanes of the present day there is some stability and some control, but, as shown in practice and explained in the foregoing, at least in part, not enough stability to make control safe and not enough control to make up for the shortcomings in stability.

All the control elements are rudders adjusted to act only when momentum is available in a direction which comes within the range of about twenty degrees on either side of the normal direction of the rudder areas, or when gravitation may be made to act within the same narrow range. There is lacking a power element which, assisted by increased stability, will produce control or rudder action when ordinary rudder action would be exhausted. For example, the machine is tipped laterally by a gust of wind, while the motor is stalled. The natural balance of the machine—and this balance must exist and does exist in every machine which is capable of descending safely when the power gives out—now permits the aviator, even if the momentum is at the minimum, which makes the tilt-rudder or deflector useless, to take the descending-tilt and gain some speed by the power of gravitation, and by means of this speed he can correct the lateral tipping by warping his planes, and he can emphasize this righting action by clever use of his side-steering rudder. Both these control actions would be of very slight effect if he could not gain speed first by gravitation. Now it is evident that in unfavorable weather he might not get sufficient time to gain speed by gravitation before the machine was upset laterally. Also, if the wind had tipped his machine backward as well as laterally—with the motor stalled and momentum gone—his natural balance, which ordinarily tends to produce a suitable descending-tilt, may be so nearly exhausted by the half-upset position of his machine in the air that he cannot get back to a safe position at all with the means at present employed. He needs the new additional control element referred to above, and, like all control elements now employed, it must be actuated by power of some kind, in order to fight the disturbing gust of air. The supposition is that the motor power has failed or has become useless for control, because the only areas it has to act upon, the customary rudders, have been thrown out of commission by the power's insufficiency to produce the progress through the atmosphere which is required for rudder action. This is the situation, when the wind throws the nose of the machine so sharply upward that the sustaining action of the planes is lost or almost lost, and it consequently remains for momentum and direct propeller thrust to overcome gravitation.

The forms of power available for the new control element are motor power, which it is not permissible to depend on, gravitation and the aviator's muscular power. All these are used in the customary control system, but their use is limited in utility by the constant relations established in the aeroplane by its designer between the direction of the power thrust and the direction of the main plane, or planes, as well as the normal direction of the control planes. It has been the gist of the foregoing remarks to indicate how the wind may make this limitation a sharp and decisive one, acting in conflict with gravitation instead of in unison with this force. Now, what is left, without changing the type of an aeroplane completely, in order to give the necessary range and power to control action? Gravitation is the only force which acts in a constant direction, wind or no wind. It ought to be the sheet anchor of the aeroplane. The motor power which is more or less unreliable and whose direction depends upon the very wind which it is meant to counteract through its influence on control planes and main planes is intrinsically not quite fit for the work. The main and control planes, which are also shifted around in the wind and whose action moreover depends on either the motor or gravitation, preferably both, are also in themselves insufficient. How can gravitation be called to work to right the machine, independently of the position which the wind has given it? By employing one constant force always available, which is the aviator's muscular power, to release the force of gravitation or overcome the force of gravitation, as the case may be, and thereby changing the relations of the main planes, to the center of gravity of the machine and to the direction of the machine's movement against atmospheric resistance.

Relative mobility of the weighty parts and the planes of the machine is the only means left for control action, after the wind has exhausted the resources at disposal in the form of natural

inary rudder action. It is also the means em-
/ by all winged creatures. The distinction be-
and rudder action is that it acts directly on the
uscular power or gravitation, while the rudders
the main planes by the intermediation of either
or gravitation, and may fail to act. Whether
of the parts of an aeroplane should be employed
the use of various small control planes or as
stomary system, is a question on which theorists
in general will naturally differ. For the avoid-
d design and the extra weight it involves, sole
itive mobility between the weighty and power
roplane, on one side, and the area elements on
uld seem to be advisable, and this would also
of the aviator. But in practice less radical
ly to prevail. The warping of wings in the
and in those of other designers who follow
le, may be mentioned as a control action akin
posed, in so far as it consists in a change in
main planes effected by direct muscular action
thout the assistance of gravitation, however.
limited scope, it is used principally for steer-
ht degree for assisting in preserving the equili-
ng of weights, especially the weight of the
been frequently proposed as a means for
sufficient for effecting quick changes in the tilt
lanes or in their lateral equilibrium, while also
cting the relations between the planes and the
pulsion. When equilibrium is to be regained,
se, that the relations at that moment existing
s elements require to be changed, and the
its the changes to be made most radically is
nd resourceful one.

e into construction details, the system which
ed as necessary for safety in bad weather
d theory, practice having shown the present
involves the rotation through a small angle
plant and the aviator, as well as the whole
anes or whatever is retained thereof, in rela-
nes.

s, the main planes or plane (if a monoplane
doubtless be divided into two wings which
parately, the motion of one compensating
her, as in warping, or the two wings may be
s for rising or descending. In the latter
control movement of the aviator will be
sisted by gravitation, according to whether
are to be raised or lowered, but under all
ect must be a mutual one; that is, the full
d between the portions carrying the power
trol members, on one side, and the carrying
h adjustability is required laterally as well
fore-and-aft equilibrium may be doubted,
ich turns one wing of a main plane sharply
affects the sustentation on that side, and it
l necessary control motions may be accom-
l means for adjusting the lateral balance,
just as no such means exist with the present system, but i
Nature all fliers have in addition the ability to raise one win
tip much higher than the other, thereby reducing sustentation o
the side which is raised most.

While there seems to be no logical escape from the necessi
of the system which has here been indicated in its large feature
the mechanical details involved in executing it mean no dout
a considerable addition to the cost of production for aeroplane
and the employment of much ingenuity to keep the weight of th
machine within bounds, since the relative movements of the tw
principal portions of such a machine as contemplated call fo
much greater strength of construction than is necessary in th
present type.

The smaller these movements may be made, while yet sufficier
for their purpose, the better are evidently the chances for devisin
a control apparatus which will not be too bulky and weighty, an
the better may all forces be economized in its operation and th
work of the aviator lightened. All other suitable means for pre
serving equilibrium, in addition to the system of relative mobilit
of parts, should therefore be employed. Among these means in
herent stability comes perhaps first, and this forms a separat
subject. But reserve power and the greatest possible reduction o
the areas of the carrying planes are also important element
The reserve power which may be thrown into the propellers an
faithfully transmitted by these driving-wheels of the aeroplan
to the responsive atmosphere will permit propulsion at a steepe
angle than a lower power will support, and may save the balanc
of the machine when the wind may have cast it around to suc
a steep angle. Generally, it is readily understood that in an
position of the machine the speed resulting from propulsion i
always a helpful factor, as the effect of every control movemen
is governed by both speed and gravitation, and speed is th
variable of these two factors. Both the development of goo
motors and the efficiency of propellers are therefore bound u
with the problem of equilibrium. With regard to the area o
the planes, this must of course be determined in part by the loa
and somewhat by the speeds which are considered maximum fo
safe starting and stopping, but, other things equal, it evidentl
serves equilibrium to employ planes with a maximum of sustenta
tion per square foot, a strongly curved plane rather than a fla
one and all improvements which may be devised to make sustenta
tion efficient, as the disturbing influence of the wind will as a rul
attack the machine with a force commensurate with the area
and without regard to their penetration or resistance to propul
sion. And the smaller resistance to propulsion is at present th
only argument in favor of flat planes or planes with small curva
tures. When operating with muscular power and gravitation a
the active factors for changing the relative positions of planes an
weighty portions, it is also evident that the small areas are mor
easily pulled to the position it is desired to give them.

It is believed to have been shown that equilibrium is not
separate property of an aeroplane or to any great degree th
result of an art of the aviator, but a product in which all factor
in the construction of an aeroplane enter deeply for consideratior
The question of inherent stability remains for separate discussior
its merit requiring treatment in a way to bring out, unhamperec
the salient features.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

WHY should the hoarders of gold cry "wolf" every time they see an automobile go by? It is easy enough to understand the mutterings of those who, in view of their cuteness, coupled with a little learning, are trying to earn their stipend. But, why should men who have money to lend want to stifle an industry? The automobile has the fault of being relatively new; for this reason it is open to suspicion. It is right to be conservative, but it is a crime to be stupidly so.

* * *

The best answer to the charge that men who cannot afford it are buying automobiles, is at the beck and call of every man in America; let him but look over his list of acquaintances, and decide for himself whether or not the owners of automobiles that he knows are beggaring themselves.

* * *

It is claimed that the automobile is a plaything; that it has no economic value; that it lures men into idleness. Must a man work his nails off, reduce himself to a stage of mute idiocy by all work and no play, and then step aside for a newer, fresher slave? Is there no sign of economic advantage in going out into God's fair country, filling his lungs with oxygen, getting a glimpse of the green fields, recouping the energies that lag, and, in fine, come back invigorated, ready to do more and better work? Is it an economic advantage to die acquiring experience?

Do bankers object to having men purchase beef to eat? Why should not these same men purchase oxygen to consume? Is beef a better preserver of life than oxygen? Is it not necessary to go to a slaughter house for beef? Can pure oxygen be had in an ill-smelling shop? Is it not an economic advantage to jump into a swift running automobile and ride out to the storehouse of oxygen for the supply that cannot be obtained otherwise?

* * *

Wise financiers long ago recognized the economic advantage of quick transportation, the liberal dissemination of information, and the results which follow when men and women learn more about each other than they are likely to know if they all stay at home. Are we to forget the fate of China; what befell 400,000,000 of the earth's inhabitants when they elected to isolate themselves and forbade communication? Is there any difference between the "Wall of China" and the wall that surrounds the man who does nothing but go to business and come home at night? His family gets to know him as a dull bore; his neighbors forget that he is on earth.

* * *

Does the economic situation demand that men shall so abuse themselves by all work and no play that they will be hated by those who do not know them excepting as dollar-chasing plodders, and hated more by those who know them best, because they are made into cranks by overwork and lack of fresh air? Must men surrender the love and esteem of all who are in a position to judge of their qualities in order to satisfy the economic situation? Can a man command love and esteem when the smile that cheers wears off, and its place is taken by a pensive drawn map of dull care? Who ever succeeded in keeping dull care as a companion in an automobile for more than the time it took to ride out past the last house and give the weazen-faced beggar one glimpse of Nature?

* * *

When the steering gear develops enough lost motion to annoy the chauffeur, it is pretty nearly time for the owner of a car to call in his family lawyer, make his will, and arrange his earthly affairs. The chauffeur is not easily annoyed; his acquaintance with lost motion, if he is the kind who waits until enough of it developes in the steering gear to annoy him, must be that which would be designated as intimate. Of course the owner of the automobile has one other choice—he can look for a new chauffeur; but before the new chauffeur accustoms himself to lost motion it will be in the path of wisdom to get a new steering gear. True, the old one might be repaired, but it is highly improbable that an ordinary worm and sector, after lost motion develops, can be corrected sufficiently to make it worth while. In any case, the class of steering gear which develops lost motion freely is probably a member of the family which has "defective design" engraved on its crest.

* * *

Judging from the character of the declarations which are being made by the makers of 1911 automobiles, descriptions of which are now rapidly coming out, the newer models are more in the nature of 1910 models refined than outright new designs.

hat the Brains of the Industry Say About Finances

Some of the "abstract" thinkers who devote their time to economic problems, not being used to efforts in a large way such as the automobile represents, are endeavoring to refrigerate the further efforts of active workers in the vineyard by means of radiant energy from "cold feet." History was made by the character of men who do things and a series of editorials, as here presented, reflect at first hand what the brains of the industry has to say about financing.

Death-Bed Speculation

H. E. COFFIN,
CIETY OF AUTOMOBILE ENGINEERS

ntlemen have recently aired vs as to the motor car pon the economic conditions . Mr. J. T. Talbot, Chan- the Hon. James J. Hill have t at the rubber-tired pests to swarm over and destroy country much as did the cal fame. Other views of ve been aptly presented by and Briscoe.

we do not all agree upon this subject. I believe ever all agreed upon any one subject since the the probabilities are that we never will.

1 of Mr. Hill's persuasion would have us all one-horse chaise in which most of us have gone e centuries past. We are surprised to note this e part of a man who owns as many railroads . We will expect next to hear him advocating ransportation of a hundred years ago.

hink Messrs. Reeves and Briscoe have replied the remarks of the other gentlemen mentioned. us to say a few words as to a few of the esti- enditures for 1910, because we are most of us cked when we hear mentioned such sums as h expressions may roll easily off the tongues of and Talbot, but they give most of us a cold ures quicken our pulse, because they represent most of us have ever thought there could be in atement that this amount will be expended this try for automobiles makes us feel more like siness affairs than did the proximity of Halley's after all, the American citizen is a pretty good e first shiver we are still willing to admit that e some money, but are inclined to get out the ow much we are spending this year for other ll of us apt to ask ourselves whether some of have in the past done or will in the future do s a nation as much good as will the automobile. r intoxicants alone during 1910 $1,800,000,000— as for motor cars. During 1910 we will spend 0,000—between two and three times as much For life insurance we will invest $550,000,000. Now, we can't help believing that a little economy in the money spent for booze and tobacco might be a very good thing for us all and it would not take very much economy upon these items to buy a devil of a lot of automobiles.

ident Society of Automobile Engineers

Life insurance is a very good thing —after a man is dead. But unless a man is 86 years of age, and has married a young wife, it is a ten-to- shot that his family would rather have spend a thousand dollars for a health- ing and life-prolonging family motor than to lay up his coin in the form of a c consolation after he has been planted. is barely possible, too, that he might prolong his life as to take care of the surance policy as well as of tires, gaso and lubricating oil. All this entirely a from the question of the pleasures in wh the family share—the evening trips into country, the Sunday rides, and the th sand and one little enjoyments so gener denied to the working man because of transportation limitations.

It is not to be expected that a lot of us should appreciate what these things mean. A good many us, like Mr. Hill Mr. Talbot, can afford to own a private car or two and do a of other things beside which the little jobs and pleasures of man who slaves ten hours a day look mean and insignificant.

Even the figures given above do not give a very good idea to our yearly expenditures for things other than these fo wheeled "calamity carts." We have mentioned only two or th of those things which might strictly be termed the "unnecessari of life. But we do not for a moment place the motor car in classification. The horseless vehicle, the pleasure and commer car are with us to stay, just as certainly as are the steam electric railways and the steamship lines—just as certainly are the telephone and the telegraph—we could not do with them. The motor car is an indispensable factor in progress

The comment, favorable or unfavorable, of such wor gentlemen as Messrs. Hill, Day, Talbot, Reeves and Briscoe r strengthen the interest in the motor car and may help to fo the attention of the country generally upon the tremend growth and importance of the automobile industry. It will help in the cause of the greatest benefit to our civilization si the days of Fulton and Stevenson—almost since the days of Ad

Our hats are off to the motor car and to the men wh work has made the motor car possible.

Payroll Goes to Great Army

By THOMAS HENDERSON,
VICE-PRESIDENT WINTON MOTOR CARRIAGE COMPANY

It is difficult to understand how money expended in the p chase of motor cars is a menace to the country's finan Finance is beneficial to any country only as money is distributed among the industries. Money while stored in banks is serving no good purpose, and when used for gambling on the stock exchange may be doing positive harm; but money expended in the purchase of motor cars is of benefit to many industries, since the

Thomas Henderson, Vice-President Wi ton Motor Carriage Company automobile makers' payroll is distributed to a great army of heads of families, who in turn distribute it to the grocer, the butcher, the clothier and the real estate dealer. The automobile manufacturer in the payment of his bills for supplies distributes money to the iron and steel industry, the lumber industry, the leather industry, the rubber industry, and the paint industry, and these industries in turn distribute the money to their employees, who in turn distribute it to the grocer, the butcher, the clothier and the real estate dealer, and in its passage from hand to hand the banks profit. What industry is injured? Is it wrong to give employment to many men and to help them live comfortably? Is it wrong to take money for a product that saves time, decimates distance, takes its purchasers out of doors, gives them service, enjoyment and health that they can secure in no other way? Suppose even that people buy motor cars who can ill afford to do so, what is the result for each such case looked at in its first light—the individual purchaser makes a mistake that cramps him, and money that he does not know how to use properly is put into circulation among the country's workers who do know how to use it; thereby the country's balance is preserved. As a matter of fact, that talk of foolish buying is largely exaggerated. Among our thousands of patrons we fail to recall one who is not amply able to maintain himself and his family without the slightest inconvenience due to his motor car purchase. The motor car industry was practically the only industry giving regular employment to men during the panic of 1907 and the years following, and an industry that can do that is one that the money industries ought to support and not hinder. Incidentally, this campaign against motor car buying seems to be prompted in but one quarter. Might it not be well to investigate that quarter?

Thoughtless Men Can Do Great Harm

By BENJAMIN BRISCOE,
President United States Motor Company

Recent spasmodic statements emanating from prominent men who have attacked the automobile as representing an economic waste, "a menace to the American home," etc., have aroused the indignation of motorists throughout the country, and statements emanating from such prominent men as James J. Hill, Chancellor J. R. Day, of Syracuse University, and Mr. J. T. Talbot, of the National City Bank, New York, call for a reply not because what they say is true, but because of their prominence. Thoughtless men can do a great deal of harm, whether those statements be founded upon facts or fiction.

During 1909 there were made in the United States, approximately, 120.000 automobiles at an approximate valuation of $150,000,000. For 1910 the indications are that there will be sold about 180,000 automobiles for which the valuation will be in the neighborhood of $239,000,000. Separating the 1910 automobiles by price, the following, I think, is a fair approximation:

Automobiles ranging in price from	Number of cars 1910 production	Selling Retailing at
$ 485 to $ 750	16,000	$8,800,000
751 to 1,000	49,000	41,650,000
1,001 to 1,250	58,000	64,000,000
1,251 to 1,600	22,000	33,000,000
1,601 to 2,000	8,000	14,000,000
2,001 to 3,000	15,000	36,000,000
Over 3,000	12,000	42,000,000

To secure a correct idea of the economics involved it is necessary to have these figures before us, because by having them we realize to how great an extent the automobile is coming to be a business vehicle. Generally speaking, all cars up to $1,250 are a very considerable part of the time used for business purposes—that is, as an aid in one way or another in production.

It is safe to say that fully half of the use of the next two classes—that is, cars selling from $1,251 to $2,000 and from $2,001 to $3,000—is devoted to commercial use. This use represents improvement in the facility of production. We may admit for argument's sake that cars selling above $3,000 represent mere enjoyment and health-giving recreation. Many business men, however, use these high-priced automobiles to and from their business at a great saving of time, with consequent enjoyment of their producing value.

Follow the dollar paid for an automobile, and what becomes of it? It is distributed for almost countless purposes. It is wages for working men; it builds their homes; it educates their children; it furnishes employment for almost every class and kind of mechanic; it circulates as lively when used in the automobile business as in any other business except perhaps banking.

The automobile has brought the country nearer the city; it has raised land valuation in nearly all sections of the country; it has cured sick people when medicine did them no good; it has made the strong stronger and the automobile is wiping out more border lines and through the automobile there will be no South, no North, no West, and no East. It is bringing the ruralite and the city folks into closer connections. It has been the cause of making hotel proprietors and merchants in country towns more prosperous and has given employment to thousands.

This, then, is the great industry which these men would lead the country to believe is an "economic waste" and a "menace to the American home." I believe that the intelligent people of this country will conclude that the automobile is worthy.

3,000,000 Automobiles for the Farmer

By FRANK BRISCOE,
President Brush Runabout Company

I believe that an understanding of the automobile business and its future will be made easier if all of us will have the courage to act on what we really believe. By taking the attitude that it is too good to be true, we not only fail to get all there is in it during the time of the "ups", but we also get into

Benjamin Briscoe, President United States Motor Company

Coker F. Clarkson, General Manager Society of Automobile Engineers

S. D. Waldon, Vice-President Packard Motor Car Company

Alfred Reeves, General Manager, Association Licensed Automobile Manufacturers

Frank Briscoe, President Brush Runabout Company

B. F. Everitt, President Metzger Motor Car Company

the habit of thinking that there can be no "downs," as is the case with every other business.

In this topsy-turvy condition, we find it a stigma of shame to have any goods to sell, and it seems to be considered good advertising to tell the public that we have fine cars, but that they will have great trouble in buying one, and that even if they place their order, they probably can't get delivery. This false standard has got to go before the business will be right.

In considering the future of the business, we have two elements—supply and demand. The demand, heretofore, has grown by itself, and we have been struggling to create a supply. We are now getting somewhere within gunshot of the present normal demand. In fact, we now hear mysterious rumors that the supply has caught up with the demand as to certain types of cars in certain places.

The present situation seems to consist of the following elements: The season for buying pleasure cars is now growing old Our bad habit of announcing next year's models nine months ahead has something to do with this marking of seasons.

In view of the vastly increased production plans for next year, we must now turn to the other end of the business, viz., the demand, and study that. There are two kinds of demand—the active and the passive. The active demand is when people insist on buying goods of their own volition. The passive demand is the kind that is created in you when the piano salesman, after camping out on our lawn for three weeks or so, finally cajoles you into a purchase, against your will and expectations.

Heretofore, we have never done much with this passive demand, although in most other lines it is the greatest end of the business. Personally, I shall welcome the time when we begin to need the passive demand. It will eliminate the high-salaried order-takers and substitute for them real salesmen who earn their money. It will prevent the wild craze to start new companies which are alike demoralizing to the trade and damaging to the public. It will also prevent serious over-production, as it will give us some idea of the limits of the demand.

I am absolutely firm in the belief that the ultimate normal demand in the United States will be upwards of 500,000 automobiles per year. We could not sell that many this year, or next year, due to the fact that the selling mechanism is not even complete enough to take full advantage of the active demand.

Before we get through, there will be 3,000,000 automobiles in daily use on farms. The average per capita used in cities is not half what it will be. Ninety per cent. of the physicians, city salesmen, collectors, grocery stores, etc., etc., etc., will have them, because they must. Gasoline excels oats in economy, speed and service. There is no other answer.

Those of us who in the time of plenty have been storing up equipment and organization against the time of need can have nothing but the most optimistic outlook for the future.

The Manufacture of Automobiles Requires Skill

By CHARLES MOORE,
Secretary-Treasurer Security Trust Company, Detroit

The supremacy of Detroit as the automobile manufacturing city of the United States is assured by the number, and particularly by the variety, of the types of machines manufactured here; and also by the production of automobile accessories here.

The location of these manufactories in Detroit was not fortuitous. The wave of manufacturing progress began in Europe after the Franco-German war had settled the status of the German Empire. When the wave reached this country articles requiring skilled labor for their production began to find a location in Detroit, until now more kinds of manufactured articles are produced in and around Detroit than in any other city in the United States.

The future of the automobile seems certain. As cities increase in size—and all the large cities in the whole world are increasing—two forces are at work. Those persons who can afford to live in the country will do so. Those persons who are forced to live in city flats will seek to get out into the open for their pleasure. Therefore, both the suburban estate and the city apartment promote the use of the automobile. The doctor, the architect, the builder and various other professions and occupations not restricted by neighborhood require the automobile. Long-distance deliveries from stores and shops already demand the use of the automobile. The farm motor now in process of development on the Ford 1,200-acre farm at Dearborn promises to do more work in a day than can be done by six men and twelve horses. At least such are the unofficial reports.

People fear that the automobile is a fad, and will disappear like the bicycle. Only a superficial view of the situation suggests a likeness. One difference between the two is that with the bicycle one rode and walked at the same time.

The courage, capital, energy and perseverance of the younger generation of Detroit business men have established the automobile industry in this city; and to-day they are devoting their abilities to strengthening the foundations of the business and putting the structure into shape. Permanency rather than expansion is now the watchword with the established companies.

Automobile Industry's Benefits Widely Diffused

By ALFRED REEVES,
General Manager Association of Licensed Automobile Manufacturers.

It is regrettable that the automobile industry cannot benefit every other line of trade. It is true that it benefits scores of different lines, but the trades not advanced naturally make the motor car the subject of criticism; pessimists now declaring that its death is near at hand, just as they have been making declarations of a similar nature for the past few years.

Never giving a thought to the economical advantages that make it an important factor in our fast-moving life, these pessimists declared at first that the motor car was only a fad; then it was stated to be a luxury for a few; then a necessity for a few; and now, with almost 400,000 motor cars in use, the business of making them has recently been termed by men (who could not have taken more than a casual survey of the situation) to be an extravagance, a waste of capital and representative of everything that is bad.

Scores of trades have benefited by the manufacture and use of the automobile, but leaders in other lines can too easily blame the modern vehicle for any slackening in the demand for their products. Some few highly respected and learned men have undertaken, presumably without investigation, to criticise the automobile business. Their position in many cases is illogical. For example, Vice-President Talbot, of the National City Bank, appearing before the Texas bankers, said that the motor-car manufacture was a woeful waste and extravagance, and indicated that the business was coming to an end. On the other hand, his associate vice-president in the same bank, Mr. H. M. Kilborn, has just organized and heads a company to make automobiles.

People of late may have declined to buy stocks and bonds (the result possibly of what they have learned from recent investigations), so we have a prominent railroad man who blames the automobile for this. Chancellor Day, not to be forgotten, follows in the same footsteps.

The many reasons for the growth of the automobile industry, the fact that it is the greatest advance in the individual transportation line since the days of the Roman chariots, and the further fact that it is almost as important a factor in the economics of the country as the railroads, all prove what grave injustice some of the leading men are doing the industry, which, without the help of Wall Street, without the blare of trumpets, but by hard work on the part of the pioneers, and scientific study, has developed into one of the greatest of American industries. Its use has not cheapened the horse nor decreased its numbers, according to figures recently published. The motor car has simply filled a place and supplied a want which has been open for years. It has enabled people to be transported, and has permitted the transportation of goods with a greater degree of comfort and safety and in faster time, and for that reason is certain to have its use increased.

It is safe to say that fifty different lines of business have been benefited by the manufacture of automobiles, which has distributed millions of dollars every year to other trades, to the real estate field, to hundreds of thousands of laborers, and to the railroads, whose freight shipments of motor cars supplies no mean part of their revenue.

The raw materials used in the manufacture of the motor car include steel, brass, iron, wood, leather, aluminum, glass, cloth, cotton, oil and electrical apparatus.

The trades which have prospered as a result of the industry are far beyond what would appear at first thought. They include machinists, blacksmiths, assemblers, pattern-makers, tool-makers, electrical workers, carpenters, trimmers, finishers, upholsterers, painters, body-builders, mill wrights, tinsmiths.

Those gentlemen, who have undertaken without careful consideration, to warn the public against the automobile industry, are doubtless now aware, through the information which has been supplied in recent articles, of the error which they committed in making statements that were apparently without foundation, and which appears to be only the cry of those who may have been slightly hurt by the advance of the motor-car industry.

Automobile the Triumph of Evolution

By COKER F. CLARKSON,
General Manager Society of Automobile Engineers

The outcry against the automobile, as to its great and increasing popularity, despite the prices at which it sells, is the hoary old cry against progress. That the world needed this improved system of quicker transportation, and was ready for it, has been proven by the immediate and well-nigh universal response to and approval of it. As the telephone, by its practical annihilation of time and distance, has in many substantial respects doubled the hours of every day for the possibilities of practical human achievement, saying nothing of its equal gifts in contribution to human comfort, happiness and manifold enjoyment, so has the automobile greatly increased the possible and even the certain chances for every man who can employ this great new agency, to very often nearly double his day's profit.

The automobile has helped to solve the problem of congestion in cities, and to make possible both cheaper and better residences in the country. In the serious menace of the past few years of the surprising and undesirable growth of city population over country population, the automobile is greatly helping to solve a most important question. It has added new hours of opportunity to every business man's day, contributed to the enjoyment and happiness of his family, and by the creation of a great industry furnished new employment to hundreds of thousands of laborers and many thousands of business men. Instead of encouraging extravagance among those who are not wealthy, it has more often taught those who had not the money to buy a machine, to economize and save to that end.

Why should rich critics deny to those who are not rich the privilege of gaining the means by which they, too, may be able, by comparative economy at the most, to enjoy this last and most remarkable invention for both human need and human comfort? The popular faith in the stories of so many homes being mortgaged to buy automobiles rests most largely, if not entirely, on false assumption—an assumption which has been created doubtless in large part by banking and deposit companies, which naturally believe that the most patriotic and wisest money is that which is kept on deposit, either without interest or at a rate very low. This is not a fitting time to impugn the sense of the large number of American families who have found in the automobile a chance to widen their lives and to increase their joy of living.

One just criticism of our people as a people has been that the average family does not aspire to and gain for itself a life with more of sane and healthful pleasure and enjoyment in it—something to brighten, inspire and gladden it, and joyously make life more worth living. That an automobile can add greatly to the happiness and greatly widen the life of any family able to buy it, no one will deny.

So with the automobile industry, risen to fifth in rank in the American industries, and paying hundreds of millions of dollars for the manufacture of machines—and in the last analysis 90 per cent. of all this money going to the pay of labor—why should college presidents and bankers and railroad presidents be unhappy over the action of many thousands of American families in finding through this great new invention an opportunity for larger happiness and enjoyment?

The automobile is simply a manifestation of the forces of evolution that are working out the world's destiny, and its appearance, in this sense, is no more remarkable than was the advent of discoveries in other lines of endeavor.

The commercial phases of the automobile are practically unlimited. The world wants labor-saving devices. The automobile is one.

From the first the automobile has been the butt of prejudice and doubt. No invention of modern times has had a more bitterly presented antagonism to overcome. The industry was not, however, to be destroyed by the prejudice of men.

The business man who now motors from his residence to his office in town, in place of traveling by train, arrives at his destination with his senses fresh and alert, and with a clear brain to tackle the day's doings. And in the evening, instead of, as under the old régime, reaching home jaded and tired out after a stuffy train journey, he enjoys a motor run which, as a recuperating agency cannot be surpassed, and is fresh for the evening.

Generally speaking, a change has overtaken the entire country as a result of the economical reliable motor car. So much for that. And don't forget that as a result of the existence of the automobile, each year there are spent (aside from the capital and men directly employed) hundreds of millions of dollars; every farmer, hotel-keeper or industrial worker in the nation receiving his portion of expenditures from the use of the hundreds of thousands of automobiles now running in this country.

On the Whole We Are Optimistic

By H. H. NEWSOME,
General Manager McCord Manufacturing Company (Detroit)

There has been a great deal said of late concerning the unprecedented growth of the automobile industry and the "calamity howler" has had his say along with the conservative and the optimistic.

Up to the present time the manufacturers of automobiles have been able to count their sales by the limit of their production and, even now, this may be done with the possible exception of one or two of the medium-priced models. There is, however, every evidence that this condition is fully comprehended by the large manufacturers, as they are now limiting their production to what conservative figuring shows they can sell.

There must be a time in every business when the manufacturing will overtake the sales and we believe that this condition is just being reached in one or two models, and the fact that the industry is reaching a point of stability where the manufacturer cannot go on building regardless of sales, must not be confused with over-production or unwarranted growth. As to the parts manufacturers, their growth is merely a reflection of the automobile builders' growth or, at least, a reflection of their judgment as to demand, because the parts people equip to execute actual orders and, generally speaking, the automobile manufacturer is a positive governor between the parts manufacturer and the automobile buying public.

On the whole we are optimistic of the future and do not agree with the frequently expressed opinion that the growth of the industry is an unhealthy or unnatural one.

Making Preparation to Double Capacity

By B. F. EVERITT,
President Metzger Motor Car Company

In my opinion the automobile business is just started. A canvass of the situation from coast to coast, which has just been completed, points to but one conclusion, i. e., the demand for good automobiles is greater than the present supply, and my company, believing in the situation, is preparing to increase capacity, first, to take care of the 800 orders that lap over present capacity, and again, in view of the positive demand indicated by a systematic call upon the trade. If the incoherent discussion of the economic situation, which is now going on, has any foundation in fact, how are we to account for the pressing demand for automobiles in general, and why are "commercials" now so rapidly filling up the places that once belonged to the realm of the horse?

Not Real Cause for Business Fright

Detroit, June 20 (Special Telegram)—The automobile industry is on a substantial footing because it is the future vehicle business, both in pleasure and commercial cars. It may have its ups and downs, and the tribulations of adjustment to permanent conditions. This is to be expected, and it is not the real cause for business fright.

(Signed) S. D. Waldon, Vice-President,
Packard Motor Car Company.

Detroit Gains Two Factories and Many Buildings

Detroit, June 20—Two new automobile companies have been formed here during the past week. They are the Hupp-Yeates Electric Car Company, $100,000 capital, which will build a new type electric, and a concern headed by Hugo Scherer and F. E. Wadsworth, of the Michigan Steel Boat Company, which will have a capitalization of $250,000 and which will build a small car of more than 20 horsepower; about 100-inch wheelbase, to weigh under 1,900 pounds. This car will sell under $1,000.

The Hupp-Ellis-Rutley Company, a building organization which will undertake the construction work for the Hupp-Yeates Electric Car Company, has also been formed.

Among the other concerns outlined during the week are the following: the Aluminum Solder Company, capital $200,000; the Dominion Stamping Company, capital $100,000, and a large concern to manufacture automobiles at Alpena.

The initial car of the University Motor Car Company, called the 'Varsity, has been finshed. It will be used by the Exalted Ruler of the Elks during the coming conclave. The regular product of this company for next year has been contracted for. The selling price of this car will be $1,300-$1,350.

Buildings to the value of $365,500, to be used for automobile purposes, were projected during the week in Detroit. The chief permits granted to members of the trade authorized the E-M-F Company to construct an addition to cost $125,000, and the buildings of the Anderson Forge Company, which will cost $73,000.

The Metzger Motor Car Company has purchased a large tract of land near Highland Park, where a number of large factory buildings will be erected in the near future. The first of these will be the truck works of the company.

Another concern even larger than the Metzger company is said to be contemplating building a factory in this section of the city.

Buicks and Maxwell Prove Winners

Pittsburg, Ind., June 15—The hill-climb that was held here yesterday was a success; thrce events being run, two of which were won by Buicks and the other by a Maxwell. The distance was 1-2 mile and from a flying start. The grade was 8 per cent. at the take-off.

In the $750 and under event a Maxwell, driven by Reeser, finished in 1:30; Maxwell, B. O. Benn, 1:39 1-2.

$751 to $1,000—Buick, Gardner, 1:57; Buick, R. R. Penn, :58 2-5; Ford, Bartee, 1:00 3-4: Ford, Ryan, 1:03 3-4; Ford, Grider, 1:05; Ford, Eikenberry, 1:10; Overland, Gardner, 1:14 2-5.

$1,001 to $2,000—Great Western, :48 4-5; Buick, R. R. Penn, :50 1-5; Buick, R. R. Penn, :52 1-5; Buick, A. Dunn, :53 1-5; Ford, Grider, :55 2-5; Ford, Ryan, :59 4-5; Oakland, 1:03; Buick, R. R. Penn, 1:06.

Boston Motorists Fight Overcharge

Boston, June 20—The Automobile Legal Association has inaugurated a campaign whereby it proposes to call a halt on hotels where motorists are charged more than other guests. Circulars have been sent out to all the members asking for confidential information of their experiences. One question asks if any garage has overcharged the motorists, and when and where this has been the case, while another one asks regarding hotels.

Some 200 members of the Massachusetts Real Estate Exchange have planned a two-days motor tour from Boston to Springfield and return for June 28-29. Many of the members own their own cars and with those supplied by Boston dealers it is expected that about 50 machines will be used. Gov. Draper and Mayor Fitzgerald of Boston will go along.

The E-M-F car that is laying out the route for the Munsey tour reached Boston Monday and left next day for the White mountains. Driver Skeggs says the roads so far have been splendid.

S. A. E. Will Soon Issue Complete Specifications

Taking Position Formerly Held by "Mechanical Branch"

The good work of the Mechanical Branch of the Association of Licensed Automobile Manufacturers, which was discontinued for various reasons, has been resumed under the direction of the Society of Automobile Engineers, and the revised specifications of materials and methods will be issued at an early date. Among the matters of moment which will be handled is the proper way to heat-treat the several grades of steel used in automobile work.

ANNOUNCEMENT has just been made at the new offices of the Society of Automobile Engineers, 1451 Broadway, New York City, that the society has completed the preparation of, and will issue shortly to its members exclusively, the most complete list of material specifications ever made for motor car engineering work.

The engineering end is the originating or creating element of the automobile business. The adherence to sound engineering principles of designing and construction spells safety and economy, both to the motor car manufacturer and to the user. Too much stress cannot be laid upon the choice of the proper material for each motor car part and too much care and knowledge cannot be exerted in the treatment of these selected materials. The reliability and the satisfactory performance of the motor car are dependent entirely upon the wisdom which has dictated the design and selected or specified the materials for its construction.

The motor car business has been largely responsible for the great development of certain materials, particularly alloy steels and other metals. The list of material specifications to be published by the Society of Automobile Engineers is not a list of theoretical possibilities, but a list of materials, the qualities of which have been thoroughly demonstrated for motor car uses. These materials are practical in that they can be purchased readily in a commercial way, can be worked economically and are in every respect suited to withstand the severe service to which they are subjected in the motor car. Individuality of design is one thing and should be encouraged. Individuality in specifications for raw materials is largely useless and should be restricted within reasonable limits. Special specifications upon materials mean high prices and a restriction of the delivery of raw materials. Standardization is a necessity of progress.

The Society of Automobile Engineers' specifications were prepared under the advice of Henry Souther, metallurgist, and are accompanied by complete notes and instructions on the method of purchasing, inspecting and handling the materials used in motor car construction, in what condition they should be ordered and how they should be treated, before and after being worked into finished parts.

The work covers such materials as low and high carbon steels, carbon spring steel, screw stock, low and high carbon nickel steel, chrome nickel steel, chrome vanadium steel, chrome vanadium spring steel, silicon spring steel, alloy steel for pressed frames, valve metals, steel castings, gray iron castings, malleable iron, babbitt metals, white brass, phosphor bronze bearing metal, valve bronze, yellow brass, aluminum alloys and all kinds of automobile-engine lubricating oil.

There is an adequate discussion of specific materials suitable for seamless tubing, pressed steel brake drums, sheet steel brake bands, and pressed steel parts of many varieties, forgings, axles, structural parts of any importance whatever, steering arms, steering spindles, levers, connecting rods, crankshafts, main driving gears, nuts, screws, steering connection pins, rocker arm pins, parts called upon to resist wear but not bending strains or severe shocks, propeller shafts, driveshafts, connecting-rod bolts, transmission gears, leaf and spiral springs, crankcases, gearcases and many other parts.

A great deal of space is given to matter on the heat treatment of steels. It has long been known that the proper heat treatment of a high-grade steel is as essential for satisfactory results as its composition.

This work will be issued only to members of the Society of Automobile Engineers, the membership of which is open to every man whose interests are of an automobile engineering nature, and whose qualifications fit him for Society of Automobile Engineers affiliation, regardless of his business connections.

Bridgeport After Open Mufflerites

BRIDGEPORT, CONN., June 20—Following complaints of hundreds of residents of this city, the Board of Police Commissioners has issued orders to Superintendent Eugene Birmingham, that every member of the department arrest violators of the State muffler law. This week the officers will start the crusade, and offenders will receive the maximum penalty in the courts. The complaints come from residents in the outskirts, who claim that passing automobiles with open mufflers make sleep impossible at any hour of the night. Investigation has proven that the greater number of offenders have come to the city from New York, and already the numbers of several have been secured. Section 6 of the general statutes of the State, which refers to the use of mufflers, provides a penalty of a fine of $1, or ten days' imprisonment, or both, for every infraction. The local authorities will strive to secure the jail sentence rather than the fine imposed in order that the custom may be stamped out.

In an interview this afternoon Police Commissioner S. E. F. Hallen said: "We are preparing to enforce the law concerning mufflers. We are going about it quietly, but believe the best results will be secured." The only difficulty which will be encountered during the coming crusade will be with the officers making the arrest.

Winners in Good Roads Tour

Charles Jerome Edwards, referee of the recent National Good Roads Tour from Atlanta to New York, has announced the winners in the various competing classes, as follows:

Division 1 A; cars selling for $800 and under—Hupmobile of N. W. Wallace, Jr., Charlotte, N. C., 20 points penalty.

Division 2 A; cars selling for $801-$1,200—Ford entered and driven by E. M. Willingham, Atlanta, Ga.; clean score.

Division 3 A; cars selling for $1,201-$1,600—Cadillac entered and driven by Dr. K. McColl, Bennettsville, S. C.; Mitchell, entered by James A. Gray, Jr., driven by R. Stowe, Winston-Salem, N. C.; both with clean scores.

Division 4 A; cars selling for $1,601-$2,000—Buick of W. E. Wimpy, driven by P. A. Parmalee, Atlanta, Ga.; 108 points.

Division 5 A; cars selling for $2,001-$3,000—Columbia, entered and driven by Marcellus Rambo, Birmingham, Ala.; Pullman, entered and driven by Norman Gallatin; both with clean scores.

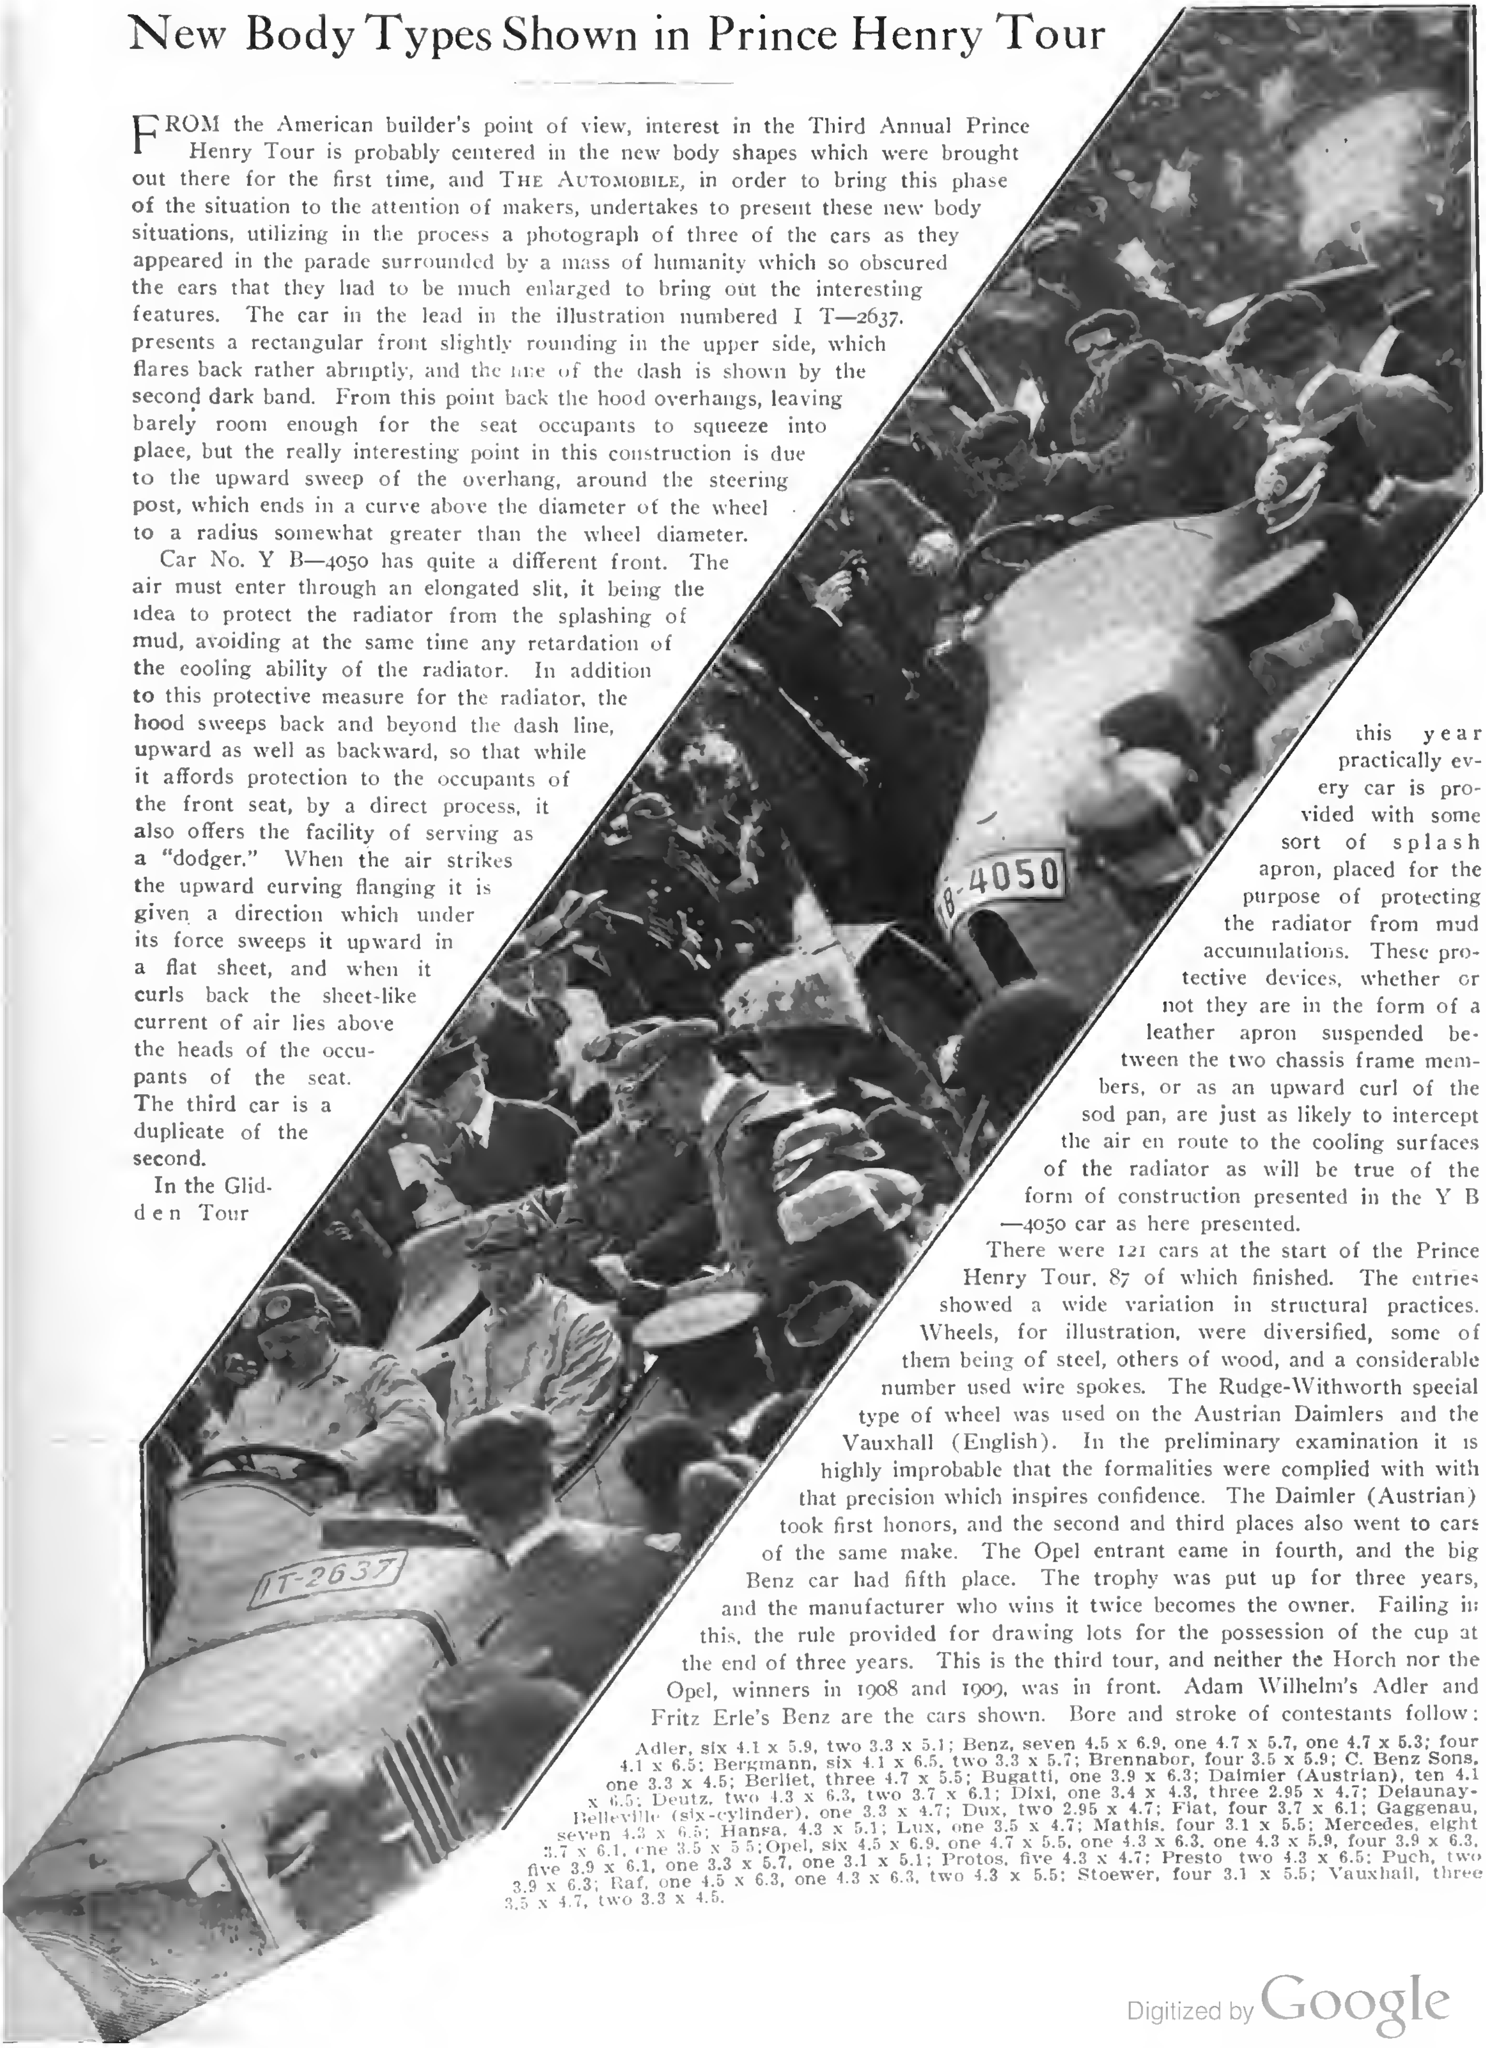
Division 6 A; cars selling for $3,001-$4,000—Pope-Hartford, entered by E. H. Inman, driven by A. L. Almand, Atlanta, Ga.; clean score.

Division 7 A; cars selling for $4,001 and up—Lozier, entered by Asa G. Candler, Jr., driven by F. H. McGill, Jr., Atlanta, Ga.; Pope-Toledo of Edward M. Durant, Atlanta, Ga.; both clean

New Body Types Shown in Prince Henry Tour

FROM the American builder's point of view, interest in the Third Annual Prince Henry Tour is probably centered in the new body shapes which were brought out there for the first time, and THE AUTOMOBILE, in order to bring this phase of the situation to the attention of makers, undertakes to present these new body situations, utilizing in the process a photograph of three of the cars as they appeared in the parade surrounded by a mass of humanity which so obscured the cars that they had to be much enlarged to bring out the interesting features. The car in the lead in the illustration numbered I T—2637. presents a rectangular front slightly rounding in the upper side, which flares back rather abruptly, and the line of the dash is shown by the second dark band. From this point back the hood overhangs, leaving barely room enough for the seat occupants to squeeze into place, but the really interesting point in this construction is due to the upward sweep of the overhang, around the steering post, which ends in a curve above the diameter of the wheel to a radius somewhat greater than the wheel diameter.

Car No. Y B—4050 has quite a different front. The air must enter through an elongated slit, it being the idea to protect the radiator from the splashing of mud, avoiding at the same time any retardation of the cooling ability of the radiator. In addition to this protective measure for the radiator, the hood sweeps back and beyond the dash line, upward as well as backward, so that while it affords protection to the occupants of the front seat, by a direct process, it also offers the facility of serving as a "dodger." When the air strikes the upward curving flanging it is given a direction which under its force sweeps it upward in a flat sheet, and when it curls back the sheet-like current of air lies above the heads of the occupants of the seat. The third car is a duplicate of the second.



In the Glidden Tour this year practically every car is provided with some sort of splash apron, placed for the purpose of protecting the radiator from mud accumulations. These protective devices, whether or not they are in the form of a leather apron suspended between the two chassis frame members, or as an upward curl of the sod pan, are just as likely to intercept the air en route to the cooling surfaces of the radiator as will be true of the form of construction presented in the Y B —4050 car as here presented.

There were 121 cars at the start of the Prince Henry Tour, 87 of which finished. The entries showed a wide variation in structural practices. Wheels, for illustration, were diversified, some of them being of steel, others of wood, and a considerable number used wire spokes. The Rudge-Withworth special type of wheel was used on the Austrian Daimlers and the Vauxhall (English). In the preliminary examination it is highly improbable that the formalities were complied with with that precision which inspires confidence. The Daimler (Austrian) took first honors, and the second and third places also went to cars of the same make. The Opel entrant came in fourth, and the big Benz car had fifth place. The trophy was put up for three years, and the manufacturer who wins it twice becomes the owner. Failing in this, the rule provided for drawing lots for the possession of the cup at the end of three years. This is the third tour, and neither the Horch nor the Opel, winners in 1908 and 1909, was in front. Adam Wilhelm's Adler and Fritz Erle's Benz are the cars shown. Bore and stroke of contestants follow:

Adler, six 4.1 x 5.9, two 3.3 x 5.1; Benz, seven 4.5 x 6.9, one 4.7 x 5.7, one 4.7 x 5.3; four 4.1 x 6.5; Bergmann, six 4.1 x 6.5, two 3.3 x 5.7; Brennabor, four 3.5 x 5.9; C. Benz Sons, one 3.3 x 4.5; Berliet, three 4.7 x 5.5; Bugatti, one 3.9 x 6.3; Daimler (Austrian), ten 4.1 x 6.5; Deutz, two 4.3 x 6.3, two 3.7 x 6.1; Dixi, one 3.4 x 4.3, three 2.95 x 4.7; Delaunay-Belleville (six-cylinder), one 3.3 x 4.7; Dux, two 2.95 x 4.7; Fiat, four 3.7 x 6.1; Gaggenau, seven 4.3 x 6.5; Hansa, 4.3 x 5.1; Lux, one 3.5 x 4.7; Mathis, four 3.1 x 5.5; Mercedes, eight 3.7 x 6.1, one 3.5 x 5.5; Opel, six 4.5 x 6.9, one 4.7 x 5.5, one 4.3 x 6.3, one 4.3 x 5.9, four 3.9 x 6.3, five 3.9 x 6.1, one 3.3 x 5.7, one 3.1 x 5.1; Protos, five 4.3 x 4.7; Presto two 4.3 x 6.5; Puch, two 3.9 x 6.3; Raf, one 4.5 x 6.3, one 4.3 x 6.3, two 4.3 x 5.5; Stoewer, four 3.1 x 5.5; Vauxhall, three 3.5 x 4.7, two 3.3 x 4.5.

To Promote the Cause of Good Roads

THE movement for good roads received its first great impetus from a private source. Colonel Pope, the pioneer bicycle manufacturer, has often been referred to as "The Father of Good Roads." He was quick to see the commercial importance, not to himself alone but to the whole country, of good roads. This participation by a business corporation in such a movement has a counterpart to-day in the efforts of a manufacturer of auto tires. The B. F. Goodrich Company, of Akron, Ohio, is setting out on a project that will synthetize the rural sections of States, identify the interests of country and city, and unite the interest of a large section of the influential public, namely, the automobile owner, on the subject of highway improvement.

Plate With Explanatory Symbols

This company is placing a sign-post at every four miles along the main highway from Cleveland to Buffalo, across to Albany, and down to New York. From New York the line of posts will run out to Philadelphia, over Long Island, and to Atlantic City and Lakewood. Farther east the posts will be put up through Connecticut to Boston, and then into the mountain resort regions of New England. After this the work will be farther extended.

The 12-foot, 4 x 4-inch post is thoroughly creosoted to make it weatherproof. On the top is the round metal sign plate, 2 feet in diameter. Through the center of this plate are drawn two arrow blades with spaces for the names of three towns—the next town, the next largest town, and the ultimate destination. Opposite each name are the distances, carefully reckoned to the fraction of a mile. Projecting out from the disc and pointing in the remaining directions are two other blades. These are brightly painted in contrasting colors so that the information is easily read by the traveler as he sits in his conveyance.

Opposite the name of a town is a symbol indicating the kind of repair, or relief, there is to be obtained. Lower down on the post is a plate bearing a copy of all the symbols together with an explanation of each one. For example, two rings, one enclosed within the other, indicate "Goodrich Tire Station"; a large solid black circle means "Gasoline Supply Station"; a hammer and wrench crossed, call attention to a "Reliable Repair Shop"; besides these are the proper designations for "Danger Crossing," "Curve Danger" and "Go Slow." In locating the posts a series of topographical maps from the United States Geological Survey has been used.

This entire scheme recognizes the new obligation of the manufacturer who makes a product that is identified so closely with the economic life of the public.

"The Vanadium" Formally Opened

In the heart of the Pennsylvania hills, at Cambridge Springs, the Vanadium, which was formerly known as the Hotel Rider, has been reopened under new ownership and with an entirely new policy of administration. The hotel is known as the "Carlsbad of America" on account of its wealth of medicinal springs and magnificent facilities for using them, is beautifully situated and is thoroughly equipped.

The management is under the personal supervision of Messrs. Matthews, Quinn and O'Loughlin, formerly of the Waldorf-Astoria.

Among its other attractions the hotel has a fully equipped garage where supplies may be obtained and minor repairs made. The most notable new feature of the hotel is the medical staff and physical instructors that have been added.

As a resort for touring automobilists the hotel is well situated and every facility for enjoyment and comfort of such parties has been provided by the management.

Motor Notes from Michigan's Capital

LANSING, MICH., Jun 20—J. Edward Roe, cashier of the Lansing State Savings Bank, has been elected secretary of the Reo Company to succeed Edward F. Peer, resigned. Mr. Roe will assume his new duties September 1. Donald E. Bates has been elected treasurer of the company.

The fourth annual orphans' day of the Grand Rapids Automobile Club was held June 15, and 200 inmates of the Blodgett Home for Children and St. John's Orphan Asylum were given an outing.

Incorporation papers of the Alpena Motor Car Company have been forwarded to the Secretary of State. The capital is $450,000, of which $300,000 is common and $150,000 preferred stock. The officers are: President, D. D. Hanover; vice-president, William Krebs; secretary and treasurer, William Roberson. The company will manufacture a four-cylinder, 35-horsepower, 112-inch wheelbase automobile, to sell for $1,450. To secure the industry, the people of Alpena gave a bonus of $50,000.

Velie Service Held Defective

MILWAUKEE, June 20—Judge W. J. Turner, in the Milwaukee Circuit Court, has dismissed twenty cases in the suit of the Velie Motor Vehicle Company, of Moline, Ill., against twenty-five automobile companies operating in Wisconsin under the name of the Association of Licensed Automobile Manufacturers. Of the five other companies, four were held to have been served and one was released. The four companies held are the Pope Manufacturing Company, the Locomobile Company, the Chalmers-Detroit Motor Car Company and the Pierce-Arrow Motor Car Company. The Peerless Company was released. The Velie Motor Vehicle Company, in its suit alleged that the defendants operated under an organization for restraint of trade and damages to the extent of $500,000 were demanded.

The Completed Post Ready for Erection

On the ground that they were foreign corporations, doing business in other states, and have no authorized agents in Wisconsin, the defendant companies had filed motions asking that the complaint be dismissed. They claimed that the dealers who represent them buy their goods in the cities where the automobiles are manufactured, the companies delivering them free-on-board at the shipping points. When paying for the goods, the money was received by the companies at the place of manufacture.

Service had been rendered upon the defendants through their alleged agents in Milwaukee, but these dealers claimed that they were not agents, that they were working for themselves, buying and selling as in any other business.

Two Weeks' Tour on Boston Streets

BOSTON, June 20—The E-M-F 30, which has been making a reliability and durability test through the streets of Boston, was stopped at 11 this morning, just two weeks from the time Charles J. Glidden gave the crank a twirl in front of the State House. When the car stopped, 3,382 miles had been covered. The gear shifts totaled 8,072, while the brakes had been applied 5,712 times. The clutch had been thrown 10,146 times.

Nailing the Explanatory Plate to the Post

Detroit Exposition Opens Doors

DETROIT, June 21—The Detroit Industrial Exposition is in full blast, having been opened on electrical signal by President Taft. The show ranks high in its class and from an automobile viewpoint is particularly impressive. Numerous 1911 models are exhibited. The show is being held in the old Wayne Pavilion, which has been much enlarged and improved for the purpose. It will continue until July 6. The following concerns are represented:

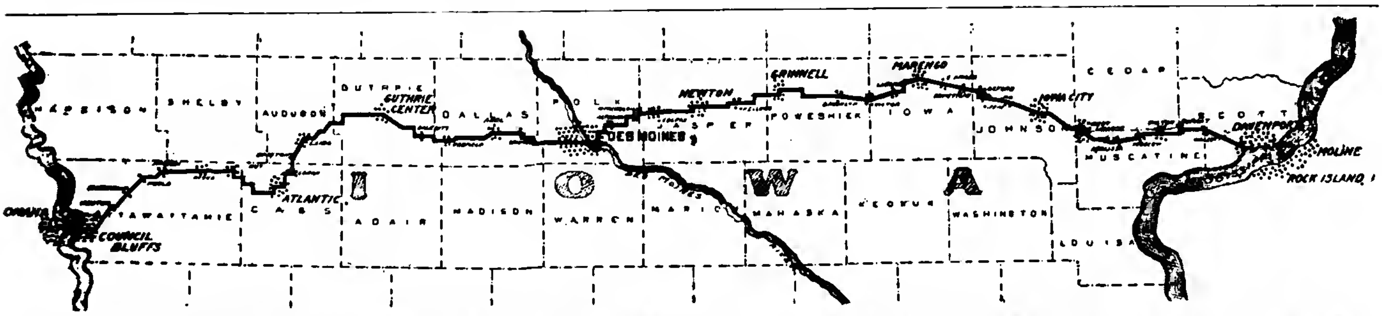
Brush Runabout Company, Brush; Cadillac Motor Car Company, Cadillac; Carhartt Automobile Corporation, Carhartt; Chalmers Motor Company, Chalmers; Everitt-Metzger-Flanders Company, E-M-F, Flanders 20; Ford Motor Company, Ford; Hudson Motor Car Company, Hudson; Hupp Motor Car Company, Hupmobile; Metzger Motor Car Company, Everitt 30; Paige-Detroit Motor Car Company, Paige-Detroit; Regal Motor Car Company, Regal; Warren Motor Company, Warren-Detroit; Anderson Carriage Company, Detroit Electric; American Motor Truck Company, American Truck; Beyster-Detroit Motor Car Company, Beyster-Detroit delivery wagon; Grabowsky Power Wagon Company, Grabowsky trucks; Stuart Commercial Car Company, Stuart trucks.

The accessory makers are:

Aluminum Castings Company, Anderson Forge & Machine Company, American Lubricator Company, American Motor Castings Company, American Motor Washer Company, Auto Marine Appliance Company, Auto Parts Mfg. Co., Briscoe Mfg. Co., Corcoran-Detroit Lamp Company, Detroit Carbureter Company, Detroit Lubricator Company, Detroit Motor Castings Company, Detroit Radiator Company, Detroit Roller Bearing Company, Detroit Screw Works, Detroit Steel Products Company, Detroit Steering Wheel & Windshield Company, Diamond Mfg. Co., Dodge Bros., Edmunds & Jones Mfg. Co., Fisher Body Company, Gemmer Mfg. Co., Gray Motor Company, Griswold Motor & Body Company, Hall Lamp Company, Hayes Mfg. Co., Hydraulic Oil Storage Company, Kelsey-Herbert Company, Kelsey Wheel Company, McCord Mfg. Co., Michigan Lubricator Company, Seitz Auto & Transmission Company, Russell Motor Axle Company, Timken-Detroit Axle Company, C. R. Wilson Body Company.

Flanders "20" Makes Progress

The Flanders "20" car, en route from Quebec to Mexico City, is now well on its way across the Mississippi Valley. The tour from Quebec to Detroit proved particularly arduous, but the car came through unscathed. Considerable progress westward and southward has been made during the past week, the course lying through Toledo, Fort Wayne, Indianapolis and Terre Haute.



Crossing the river at Davenport Miss Scott will strike the long trail on her way towards the setting sun, passing Iowa City, Marengo, Grinnell, Newton, Des Moines, and from there on, as the map here shows, landing in Council Bluffs. The Overland will be given a test over all kinds of roads—the run will extend to the coast.

The Contest Rules of 1910

By HOWARD E. COFFIN, Chairman of the General Rules Committee of the Manufacturers' Contest Association

THE 1910 rules governing motor car contests in this country provide classes in which may be entered anything from the "one-lunger" to the biggest six- or eight-cylinder road locomotive that has been or can be built. They provide classes wherein can be entered *bona fide* stock cars and yet other classes for cars of special construction built for racing only.

An especial effort has been made to restrict "stock car" events to those cars which are really "stock" in accordance with the meaning of this term in the mind of the public.

The 1910 definition of a stock car is as follows: "A motor car, the complete description of which, upon the official blank provided for the purpose, has been filed with the main office of the technical committee of the contest board at least thirty days prior to the date of the contest entered, the quantity production of which bears to the total yearly production of its manufacturer the ratio set forth in the following table, and which is on sale through the regular selling representatives of the manufacturer."

At the discretion of the contest board, any competitor may be required to file a bond of $5,000 that the entry made by him is a *bona fide* stock car within the meaning of this definition:

Total Output	Percentage	Number of Same Model
10,000 cars or more	4.5% equalling	450 cars minimum
8,000 cars to 9,999	5.0% equalling	400 cars minimum
6,000 cars to 7,999	6.0% equalling	360 cars minimum
4.000 cars to 5,999	7.0% equalling	280 cars minimum
2,000 cars to 3,999	8.0% equalling	160 cars minimum
1.000 cars to 1,999	9.0% equalling	90 cars minimum
500 cars to 999	10.0% equalling	50 cars minimum
200 cars to 499	16.0% equalling	40 cars minimum
100 cars to 249	30.0% equalling	30 cars minimum
50 cars to 99	50.0% equalling	25 cars minimum

Percentages are calculated on actual total output. For example, if the total annual output of a manufacturer is 2500 cars, at least 8 per cent. of said output, or 200 cars, must be of the same model in order to constitute such model a stock car.

During past seasons the records of the technical committees have shown many evasions of the stock car rule. These unsatisfactory conditions led to the formation about a year and a half ago of the Manufacturers' Contest Association, embracing within its membership nearly all the leading motor car makers.

As showing the scope and purpose of the organization, section 8 of the by-laws is quoted herewith in its entirety:

"The special rules and classification committee shall prepare classifications and formulæ applying to all contests. It shall submit on or before Sept. 1 of each year to the contest board, or its successors, or a similar board, recommendations as a basis for creating general contest rules to govern for the succeeding year."

It will be seen that the rules and conditions governing motor car contests have been evolved by a co-operative action upon the part of the representative motor car manufacturers of America.

The general rules committee, which has adopted the formulæ and classifications governing stock car and other contests, is composed of representatives of the following concerns: Chalmers Motor Company, Apperson Brothers Automobile Company, Buick Motor Company, Hudson Motor Car Company, Dayton Motor Car Company, E-M-F Company, Fiat Automobile Company, Nordyke & Marmon Company, H. H. Franklin Automobile Company, Knox Automobile Company, Locomobile Company of America, Lozier Motor Company, Maxwell-Briscoe Motor Company, Mitchell-Lewis Motor Company, National Motor Vehicle Company, Pierce-Arrow Motor Car Company, Renault-Frères selling branch, F. B. Stearns Company, E. R. Thomas Motor Company and The White Company.

Among the membership of the Manufacturers' Contest Association are the names of the following well-known makers: Apperson Brothers Automobile Company, American Locomotive Company, American Motor Car Company, Buick Motor Company, Brush Runabout Company, Benz Auto Import Company of America, Chalmers Motor Company, Columbia Motor Car Company, Dayton Motor Car Company, Everitt-Metzger-Flanders Company, Fiat Automobile Company, H. H. Franklin Manufacturing Company, Hol-Tan Company, Hudson Motor Car Company, Hupp Motor Car Company, Knox Automobile Company, Locomobile Company of America, Lozier Motor Company, Maxwell-Briscoe Motor Company, Mora Company, Marquette Motor Company, Mitchell-Lewis Motor Company, Matheson Automobile Company, Moline Automobile Company, Metzger Motor Car Company, National Motor Vehicle Company, Nordyke & Marmon Company, Olds Motor Works, Oakland Motor Car Company, Peerless Motor Car Company, Premier Motor Manufacturing Company, Pierce-Arrow Motor Car Company, Palmer & Singer Manufacturing Company, Renault Frères selling branch, Reo Motor Car Company, Selden Motor Vehicle Company, F. B.

Col. Roosevelt, Theodore Roosevelt, Jr., and Miss Alexander Leaving Douglas Robinson's House in the White Steamer

White Steamer Ambulance Used by the National Volunteer Aid Association During the Reception to Col. Roosevelt in New York

Stearns Company, E. R. Thomas Motor Company, The White Company and The Willys-Overland Company.

So flagrant did the abuse of the spirit of the stock car rule become in the contests of 1909 that the public naturally began to be extremely skeptical upon all matters touching stock cars and stock car competitions. That this feeling upon the part of the public (the owners and prospective owners of thousands of motor cars) did and does exist has been clearly proven by the many inquiries upon such matters which have been registered with the several technical motor car papers of the country.

Upon the contest board of the A. A. A. falls the administration of those rules which have been accepted by the manufacturers as for the best interests of the motor car industry as a whole. Motor car racing, if followed consistently by the manufacturer, is entirely too expensive to make it a matter of sport. If it is to be a matter of business, a source of publicity and a means of demonstrating to the buying public those qualities of motor car construction and endurance which must recommend his product for the every-day use of the purchaser, then certainly there can be no objection to the introduction into motor car contest affairs those same principles of honest business administration which the manufacturer and the public would expect to maintain in any other line involving similar expenditure of money and effort.

Moreover, the maker who elects to obtain through stock car racing and contest work those important advantages in an engineering, publicity and selling way, and who goes at it honestly, making entry of his *bona fide* stock product, cannot be blamed for insisting upon an impartial administration of those rules.

In stock chassis racing it is recognized that certain changes in equipment and arrangement of parts must be permitted for considerations of the safety both of occupants and spectators.

That the contest board might be given the necessary authority in the administration and enforcement of these rules, the following three rules were drafted:

First: It is the intention of the rules relating to stock car and stock chassis competitions that such competitions shall be restricted to those cars identical in specification, materials, and design with the manufacturer's product which is manufactured in quantity and is offered for sale and sold in a *bona fide* manner to the public through the regular agencies of the manufacturer.

E-M-F Pathfinder on the Road Between Somerville and West Point

E-M-F Pathfinder Crossing Bridge Over Gorge at West Point. The Car Is Well on Its Way Toward Its Goal

Second: In the event of evasion on the part of entrants of the spirit of the "stock car" or "stock chassis" definition concerning points not definitely stated in these rules, the contest board shall have full power to render such decision as it may deem for the welfare of the sport and industry.

Third: In any case where it may be necessary to establish the status of any car alleged to be a stock car under the definition contained in these rules, the technical committee of the contest board shall have the right to visit the factory of the manufacturer of such car, who shall be required to submit to the committee such evidence as it may require to verify the allegation on which the "stock" status of the car is based.

The technical committee shall also have power to take possession of any competing car, and make such examination thereof as may be necessary to establish its "stock" status.

Results of "Montauk Light or Bust" Run

With sixteen clean scores out of an entry list of thirty-seven, the "Montauk Light or Bust" two-day endurance run around Long Island of the Motor Contest Association was finished last Wednesday. The course aggregated 380 miles, and nearly fifty miles of the first day's run was through the Montauk Point badlands, as hard a bit of going as can be found in Long Island.

Four out of the five Buicks that competed finished the run with perfect scores, while two Mitchells out of three avoided penalization. The run was accomplished under favorable conditions and was successful in every way. W. J. Morgan, who has retired as head of the association, will be succeeded by E. L. Ferguson. The summary of the results:

Division 1A—$800 and under—

No.	Car.	Entrant.	Driver.	Penalty.
24	Hupmobile	F. L. C. Martin Auto Co.	Elmer D. Cutting	0
43	Hupmobile	F. L. C. Martin Auto Co.	R. E. Gillam	1010

Division 2A—$801 to $1,200—

No.	Car.	Entrant.	Driver.	Penalty.
20	Mitchell	Mitchell M. Co. (Bklyn)	D. M. Hasbrouck	0
32	Ford	Ford Motor Co.	W. B. Young	0
37	Buick	Buick Motor Co.	Charles Jones	0
31	Ford	Bishop, McCormick & Bishop.	McCormick	38

Division 3A—$1,201 to $1,600—

No.	Car.	Entrant.	Driver.	Penalty.
19	Mitchell	Wm. Simonson (Mineola)	Wm. Simonson	0
25	Chalmers	Continental Tire Co.	E. Miles Welch	118
44	Studebaker E-M-F	Studebaker Bros. Co.	E. A. Taylor	0
45	Staver	Short & Wright	C. S. Cheney	0
11	Regal	Regal-Detroit Auto Co.	George Ainslee	1000

Division 4A—$1,601 to $2,000—

No.	Car.	Entrant.	Driver.	Penalty.
36	Buick	Dr. Wm. H. Nafis	Dr. Wm. H. Nafis	0
38	Buick	Buick Motor Co.	W. Davenport	0
39	Buick	Buick Motor Co.	Phil. Hines	0
40	Buick	Buick Motor Co.	Frank Remson	8
35	Westcott	Dunlop-Taylor Co.	Thomas Wilson	79
1	Pierce Racine	Samuel W. Fromm	W. A. Wells	1000
2	Cadillac	Detroit-Cadillac M. Co. Award held up	L. R. Burne	1000
16	Auburn	LaDue-Carmer Motor Co.	Herbert F. Earl	1,000
34	Elmore	John L. Gwyer, Jr.	J. L. Gwyer, Jr.	1048

Division 5A—$2,001 to $3,000—

No.	Car.	Entrant.	Driver.	Penalty.
4	Haynes	W. E. Shuttleworth	W. E. Shuttleworth	0
18	Mitchell	Mitchell M. Co. of N. Y.	O. R. DeLamater	9
5	Mercer	Mercer Auto Co.	Joseph Trehou	1000
12	Franklin	Franklin Auto Co.	C. J. Hickman	1000
27	Selden	Cloud-Marts Auto Co.	Richard Carter	4

Division 6A—$3,001 to $4,000—

No.	Car.	Entrant.	Driver.	Penalty.
6	Palmer-Singer	Fred J. Titus	Fred J. Titus	0
13	Franklin	Franklin Auto Co.	Paul Harvey	0
17	Matheson	Matheson Auto Co.	Neil Whalen	0
41	Welch-Detroit	Buick Motor Co.	C. V. Searing	0
29	Knox	Knox Automobile Co.	H. K. Sutherland	15
3	Palmer-Singer	Palmer-Singer Mfg. Co.	A. P. Palmer	129
28	Palmer-Singer	R. D. Apperson	A. N. Henderson	180
42	C. G. V.	C. G. V. Import Co.	Arthur Coombs	356

Division 7A—$4,000 and over—

No.	Car.	Entrant.	Driver.	Penalty.
30	Amplex	Henry F. Siebert	Harold W. Sisop	0
8	Zust	American Zust Motor Co.	V. P. Pisani	30
10	Amplex	S. J. Wise & Co.	Walter Jones	1000
15	Fiat	Hugo Ricca	Peter Smith	1000
25	American	American Auto Co.	Earle A. Cryne	1034

CAUSES OF PENALIZATIONS

Division 1A—Hupmobile, No. 43, for motor stop, 9 for replenishments, 1000 for dropping out.

Division 2A—Ford, No. 31, 38 for replacing balls in bearing.

Division 3A—Chalmers, No. 25, 118 for stalled motor and time lost from car being stuck in the mud. Regal, No. 11, 1000 for rear differential trouble, causing withdrawal.

Division 4A—Buick, No. 40, 8 points for lateness. Westcott, No. 35, 1 for motor stop, 78 for lateness. Pierce-Racine, No. 1, 1000 for withdrawing on second day. Auburn, No. 16, 1000 for withdrawing by reason of broken axle. Elmore, No. 34, 40 for gearbox adjustments, 2 for motor stops, 6 for replenishments and 1000 for withdrawal.

Division 5A—Selden, No. 27, 1 for cut fan belt, 3 for taking on water, 4 for cleaning lubricator belt. Mercer, No. 5, 1000 for failing to check in at noon control and withdrawing; continued as noncontestant. Franklin, No. 12, 1000 for withdrawal due to magneto trouble.

Division 6A—Knox, No. 29, 15 for adjustments and replacing plugs. Palmer-Singer, No. 3, 6 for replenishments, 123 for lateness. Palmer-Singer, No. 28, 2 for stalling motor, 178 for lateness. C. G. V., No. 42, 1 for motor stop, 47 for engine repairs; 309 for lateness.

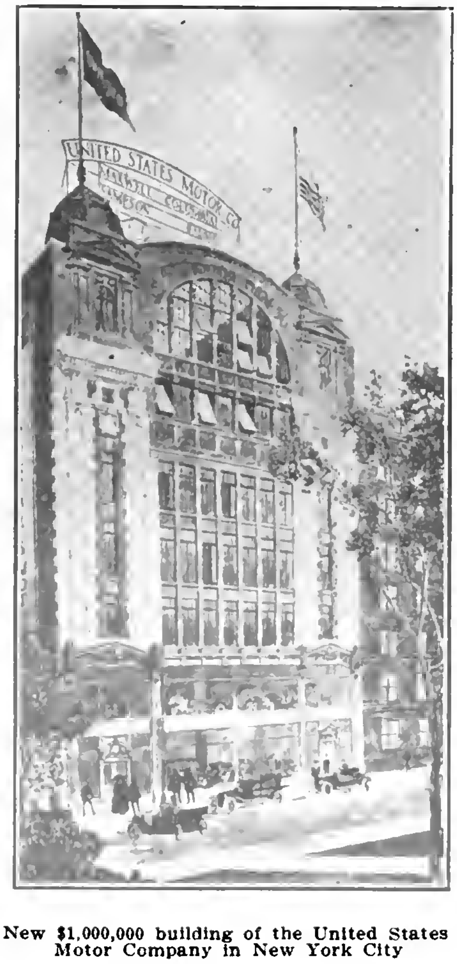
Division 7A—Zust, No. 8, 30 for removing carbon from igniters. Amplex, No. 10, 1000 for failure to check in at first control. Fiat, No. 15, 1000 for withdrawal on account of accident. American, No. 25, 34 for replacing spark plugs, 1000 for withdrawal on account of fire.

In the Realm of the Makers

Henry K. Holsman, formerly president and engineer of the Holsman Automobile Company, is now with the Independent Harvester Company, and the company is equipping factory No. 2 for the manufacture of a line of automobiles, motors, etc., under the Holsman patents.

President Benjamin Briscoe has announced that the Pittsfield plant of the Alden Sampson Mfg. Co. will be doubled in capacity. Ground will soon be broken for a building 170 by 70 feet, and an additional story is to be erected on the present main building, which is 85 by 100 feet. A new forge and blacksmith shop 60 by 100 feet and a paint and testing room 40 by 150 feet will also be erected immediately. An investment of $125,000 for new machine tools has been made, and a new building to be used as an engineering department, drafting and testing laboratory will be added to the plant.

Announcement is made that the Inter-State Automobile Company of Muncie, Ind., has been granted a license under Selden Patent No. 549,160. The Inter-State Company markets cars selling at $1,750 and at $2,000. Thomas F. Hart is president and general manager. The other officers are J. M. Maring, vice-president, and Otto Holdren, secretary-treasurer.



New $1,000,000 building of the United States Motor Company in New York City

The latest addition to The White Company's line of steam and gasoline cars and motor trucks is a new type of closed car known as the White gasoline coupé. The steering wheel and operating levers are located within the closed body and the operator is thus afforded protection from rain and cold.

The Fal Motor Company of Chicago has increased its capital stock from $200,000 to $500,000. The officers of the company remain the same. The Fal-Car is now in its second year.

James F. Baines, service manager of the Packard Motor Car Company, died at his home in Detroit, last Sunday afternoon, aged 35. His death was very sudden, being caused, it is believed, by ptomaine poisoning.

Franklin Car at Chimney Rock, 27 miles from Laramie, Wyo., 8,000 ft. above sea level

Henry F. Tully, a certified public accountant of Detroit, has joined the office force of the Clark Power Wagon Company, at Lansing, Mich.

Frank Dunnell has left the Ford factory to become assistant Ford manager at Atlanta, Ga. E. T. Backus, of Detroit, has joined the Ford branch at Houston, Texas.

Bert Morehead, Detroit branch manager for the B. F. Goodrich Company, is following the Glidden tour's progress by train to look after the interests of Goodrich tires.

C. E. Wheeler, with the H. H. Franklin Mfg. Co. for a number of years, is now with the Owen Motor Car Company, of Detroit, and will cover the territory east of Buffalo.

Sidney J. Stern, formerly New York City representative of the Automobile Trade Directory, has been promoted to the management of the Detroit office, just vacated by the resignation of C. K. Brauns.

Lambert Hollander, of the firm of Gray & Davis, makers of automobile lamps at Amesbury, Mass., has sold his interest in the concern to S. Preston Moses, of Boston. Mr. Hollander has retired from business.

C. K. Brauns, formerly representative of the Automobile Trade Directory, located in Detroit, has become vice-president and sales manager of the Radle-Clark Sales Company, which has contracted for the entire output of the Clark power wagons.

Joseph N. Spining, formerly with the Cincinnati Tire Company, Cincinnati, O., has severed his connection with that firm.

John W. McCrea, formerly with the Winton Motor Carriage Company, has assumed the office of secretary in charge of sales with the Standard Sales Company, of Detroit, which firm deals largely in parts for automobile manufacturers.

F. O. Durfee has joined the sales force of the Owen Motor Car Company of Detroit, and will be in charge of the Southern and Southwestern territory, including Florida, Tennessee, Alabama, Arkansas, Mississippi, New Mexico, Texas and Oklahoma.

Captain William Mitchell Lewis, president of the Mitchell-Lewis Motor Company, of Racine, Wis., and his family, returned recently from an automobile trip from Paris to Venice. Captain Lewis used a Mitchell six-cylinder car in making the trip. The whole party returned well, and declared the tour was a perfect success.

Twenty-five automobile owners of Ellwood City, Pa., have formed the Ellwood City Automobile Club with these officers: President, A. C. Frey; vice-president C. F. Buchanan; secretary D. H. Muchaly; treasurer, J. W. Offutt. The club will wage an active campaign for good roads and will act in conjunction with the Lawrence County Automobile Club, of New Castle, Pa., which has offered a prize for the best piece of road made in that county this year.

Fred R. Leuscher, at one time having a string of about fifty playhouses, has practically retired from the theatrical business to engage in the automobile business. He has become Rochester, N. Y., representative of Thomas B. Jeffery & Company, manufacturers of the Rambler cars, and has opened a garage at 745 Park avenue.

The tie for the first prize in the recent big Premier run from Philadelphia to Cape May between Charles H. Clinton, of Philadelphia, and M. S. Shakespeare, of Haverford, was decided by the toss of a coin, the former guessing the right side.

Kelly-Springfield Trophy for winner in Division 1 Class C, in Norristown Club's Scranton Run

The Hartford Auto Parts Company, Hartford, Conn., is opening a branch office in Detroit, Mich. This concern has added a complete line of cone clutches to its product. The success with this clutch is, no doubt, due partly to the fact that it is furnished with a double set of Universal joints of the trunnion block type. F. L. Martin, secretary and sales manager, will be in charge of the office for the next two or three months with temporary headquarters at the Pontchartrain Hotel.

E. D. Dunning, formerly with the Atwater-Kent Company, has taken hold of the Ohio car end of the G. Hilton Gantert Company's Philadelphia agency business, Mr. Gantert looking after the company's Stearns interests.

F. D. Dorman, formerly secretary of the Maxwell-Briscoe Motor Company, and more recently secretary of the United States Motor Company, was elected vice-president and general manager of the Maxwell-Briscoe Motor Company, with headquarters at Tarrytown, New York.

J. B. Hulett has resigned as sales manager for the Robertson Motor Car Company of Minneapolis, to become Western sales manager for the Owen Motor Car Company, of Detroit. He hopes to establish the Western headquarters of the company in Minneapolis.

Agency and Garage News

J. B. McCarthy, for six years with the English Daimler Company and seven years a member of the auto colony in New York, has bought the Fulton Garage on Auburn avenue, Atlanta.

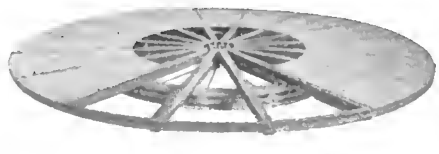
Collins & Company have taken the State of Michigan agency for the Marmon car, and are temporarily located at 732 Woodward avenue, Detroit. The Clark power wagon will also be handled, as well as several other makes to be announced later.

The North Jersey Motor Car Company has removed from 27 Washington place, East Orange, to 16 Railroad place, that city. The company has awarded the contract for the erection of a new garage on McKinley avenue, East Orange.

The E. R. Thomas Motor Branch Company, of Boston, is to have a new home, upon which it is planned to spend $200,000. It will be built at 915-921 Boylston street, on a site now occupied by tenement buildings. The exterior construction will be in French-Gothic style, with a façade of white, glazed terra cotta and large steel bay or show windows. The first floor will be occupied as show rooms, executive offices and dressing rooms, while the clerical force will be located upon a mezzanine in the rear. It is intended to have the new building ready for occupancy this fall. Turntables, said to be the largest ever built for the purpose, will be installed in the basement, second, third and fourth floors.

THE ELLIOTT GARAGE TURNTABLES

The private owner who builds his own garage must take the turntable proposition into consideration if work is to be facilitated upon his car, or cars. The Sterling-Elliott Company, of Newton, Mass., is making a specialty of wood- and steel-top turntables, which have many points of excellence to recommend them, not only to the private owner, but to the public garage manager as well. These tables are made in



Elliott Steel-Top Turntable

four sizes—12, 13, 14 and 15 feet in diameter, and are ball-bearing throughout. It is claimed for them that they run true, turn freely, are self-contained, require no oil, carry the heaviest cars without trouble and may be locked at any point. Drawings and specifications for any class of foundations are furnished upon request, so that an architect who is building a garage for a patron may incorporate one or more of these tables in his plans.

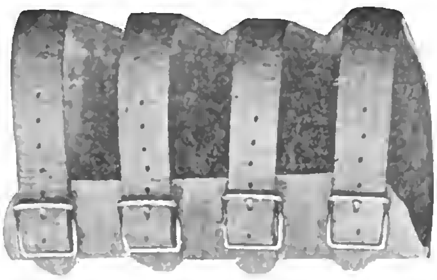
William L. Hibbard, of Milwaukee, Wis., has been appointed district representative of the Grabowsky Power Wagon Company in Wisconsin. Mr. Hibbard formerly was president of the W. L. Hibbard Motor Car Company, which handled the Chalmers-Detroit, Hudson and Thomas lines. Recently he has been associated with the Milwaukee branch of the McDuffie Automobile Company.

William Parkinson, the agent for the Overland and Marion in the Oranges, has leased the big fireproof garage formerly occupied by the North Jersey Motor Car Company, at 27 Washington place, East Orange.

The Regal car is now being handled in the Quaker City through a branch, the Philadelphia Regal Auto Company having succeeded the former agents, the Thomas M. Twining Company, at the same address, 330 North Broad street. R. M. MacCormack will manage the new branch.

ANTI-BLOW-OUT EMERGENCY PATCH

This handy device, which is manufactured by W. C. Davis, 1133 North Main street, Montello, Mass., will add considerable life



Anti-Blow-Out Davis Emergency Patch

to an old tire-shoe. It is made of unsplit horsehide, and will prevent weak places from blowing out. It is sold in sizes 3 1-2, 4, 4 1-2 and 5 inches for automobile use.

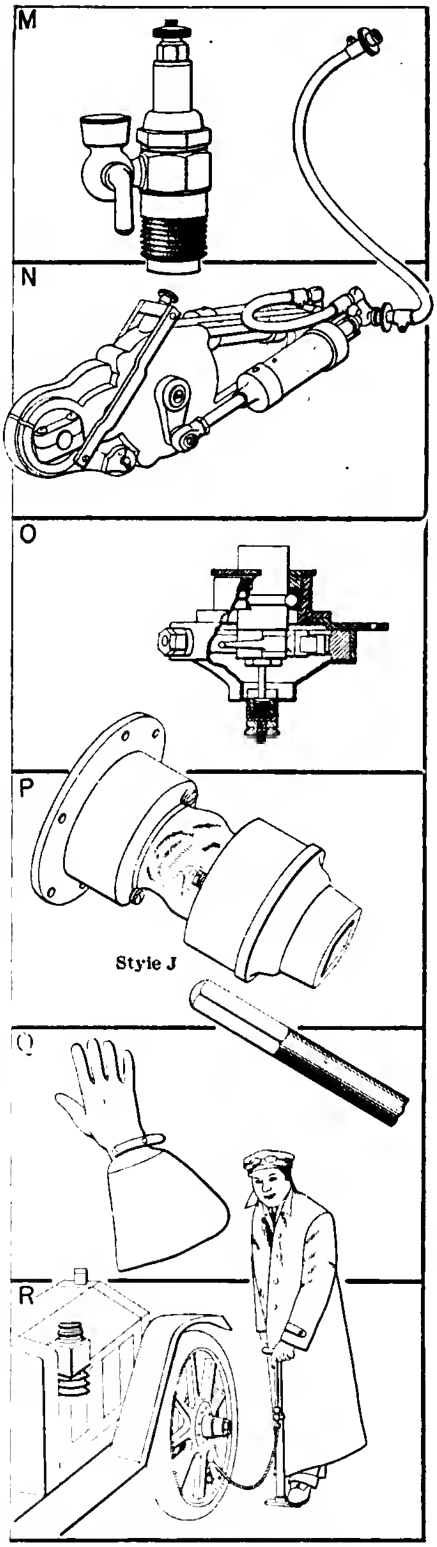
Worcester (Mass.) Motor Mart

Seen in the Show Window

WHILE sooty spark plugs may be more annoying to the aviator than to the autoist, they are yet sufficiently productive of profanity in the latter that any contrivance which promises to eliminate them, or even to materially minimize the nuisance, will be welcomed by the motoring fraternity with open arms. Such a device seems to be the All-in-One spark plug (M), now being marketed by the Buffalo Carbureter Company, of Detroit, Mich. Among the advantages claimed for these plugs are that by the mere opening of a stop-cock any accumulation of soot can be blown out instanter; a missing cylinder can be at once located by turning the petcocks; knocking in the motor can be stopped by priming with a few drops of kerosene, etc. This plug would seem to be just what is needed by the autoist who would sidestep the annoyances concomitant with imperfect gasoline combustion.

ALTHOUGH the development of muscle is all very well, and conducive to eager appetite and good digestive functions, it does not follow that the automobilist is so wedded to ancient, even if health-giving, customs that he will overlook the advantages inherent in such an article as the Quick Detachable Power Air Pump (N), recently put on the market by the Kellogg Manufacturing Company, of Rochester, N. Y. This pump will fill a tire in jig-time, and while its use may deprive the exponents of healthy exercise of the doubtful benefits derivable from hand pumping, it is a mighty handy thing to have around when one is in a hurry. Its attachment to almost any make of car is only a matter of mounting a split gear on some exposed shaft. The jaws of the pump clamp over this gear.

IN view of the fact that it is considered desirable to have a double ignition system, it is common practice to employ a magneto in the main, and a battery with a spark coil and a timer for the auxiliary work. The section (O) of the Leavitt Improved Wipe Contact Timer, as here depicted, is offered by the Uncas Specialty Company, of Norwich, Conn., for this exacting work. It is said to be an improved form of Lacoste Timer, and one of the detailed refinements to which attention is called is in the shape of a supplementary ground terminal, whereby contact is rendered doubly sure. In addition to this electrical refinement, an adjustable ball bearing is utilized instead of a plain bearing. The two principal faults in the original Lacoste idea are in these ways removed.



M—The "All-in-One" Spark Plug
N—Kellogg Quick-Detachable Power Air Pump
O—Leavitt Improved Wipe Contact Timer
P—Blood Bros. Dust-Proof Universal Joint
Q—The Hansen Perfect-Fitting Gauntlet
R—The Stapley Compound Hand Air Pump

IT has been found that universal joints, as they have to do service in automobiles, are likely to give out much too soon unless they are protected from the silt of the road. It is no easy matter to furnish this protection, and afford all the other qualities besides. Blood Brothers Machine Company, Kalamazoo, Mich., who have long given matters of this sort attention, solved the problem in the manner as here indicated (P), which is of the Style J (double) joint. In addition to the dust-proof qualities which are obtained by fastening a leather boot between the two flange couplings, the joint is of substantial construction and may be adequately lubricated.

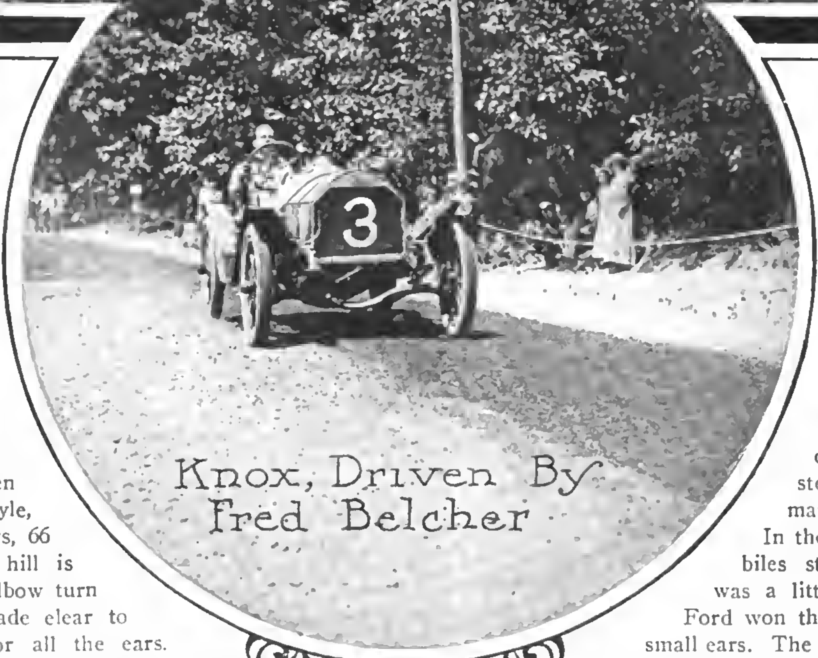
THE autoist who judges things by their utility only will not hesitate to invest when he can secure beauty of appearance along with the substantial quality which he always insists upon. This is especially applicable in the case of driving gloves, some of which are so undoubtedly built for service that all idea of dressiness seems to have been lost sight of. The O. C. Hansen Mfg. Co., of 335 East Water Street, Milwaukee, Wis., evidently had the dual idea of beauty and economy in mind in designing its No. 390 Auto Gauntlets (Q), which are made of a special tannage of black or tan leather or tan horsehide. They fit perfectly and do not cramp or bind the hands, being extremely soft and flexible. Being made with adjustable wrist strap and button fastener the wearer is enabled to have them tight or loose at the wrist, as he prefers. They are furnished with ventilated backs for summer use, if desired.

TO the legion of motorists whose cars are not equipped with power air pumps it is especially desirable that the hand pumps they carry are sufficiently powerful to deprive the work of filling tires of some of that onerousness which makes it hard labor. The Stapley Compound Pump (R), made by the Bridgeport (Conn.) Brass Company, whose headquarters are at 104 Crescent Avenue, is guaranteed by its makers to inflate tires quickly, easily and with little effort. Rustless because of its seamless brass tube cylinders, and positively non-leaking, its automatic tire valve-opener allows the tire valve to close without any loss of air.

HOW to keep the body finish up to standard is a difficult task and "Auto Renew Gloss" furnished in quarts by the Superior Specialty Company, Louisville, Ky., is regarded as effecacious for the purpose.

THE AUTOMOBILE

Knox Wins Feature Events on Port Jeff Hill



Knox, Driven By Fred Belcher

SPORTSMANLIKE, spectacular and satisfactory about describes the first annual hill climbing contest of the Automobile Club of Port Jefferson, L. I., held Saturday on Port Jeff Hill, a short, but trying, incline leading up from the level of Long Island Sound to the wooded crest of the first ridge.

The program of fifteen events filled in splendid style, and of the 90 entered cars, 66 actually competed. The hill is 2,000 feet long, with an elbow turn followed by a terrific grade clear to the finish—a fine test for all the cars.

The aristocratic residents of Port Jefferson turned out in force to witness the stirring contests and the cliff alongside the finish was lined with expensive cars occupied by dozens of prominent society women of New York. They experienced a lot of sensation during the running off of the program, but not a single mishap marred the satisfaction of the day.

A Knox car entered by Gerard and Hall, and driven by Fred Belcher, carried off the premier honors by winning the cups offered for its class, both in price classification and piston displacement, and by finishing third to the two Fiat special cars in the free-for-all. This car covered the course in the latter event in 27:61, while in the 301-450 cubic inches displacement event it won in 28:60. Protest was entered against the winner by J. Bell, who drove the Chalmers in all three events in which the Knox car competed. Of course, the protest was not lodged against the Knox in the free-for-all, as the claim of Mr. Bell was to the effect that it did not measure up to stock car qualifications. This matter will be decided later.

In the first event three Hupmobiles started and the best time was a little over 70 seconds. The Ford won the second event from three small cars. The third race went to the Correja rather easily, and one of the Buicks outclassed its field in the fourth event, winning by about 12 seconds. This car was the only one of the Buick team to have any racing luck during the afternoon.

The Matheson entry had an easy time taking the cup in its class, and the Houpt-Rockwell, which has had some difficulty in gaining entry, heretofore, as a stock car, landed the event for high-priced stock cars. The Fiat pair came perilously near somersaulting after the sharp turn in the free for all, showing, by their performance, the big advantage they had in the matter of engine power. De Palma swerved so far in making this turn that his machine seemed to be traveling on two wheels.

Aside from the showing of the Knox car in this race, the feature of it was the performance of The Only Car, an automobile built not far from Port Jefferson. This car is a one-lunger of high power and, of course, had no chance to win anything against its field. But the machine chugged its way to the top of the hill without seeming to be extended, making the course in 40:29, amid the cheers and applause of the Port Jeffersonites.

The other events were won by a Pope-Hartford, Knox owned by Mrs. J. N. Cuneo, Velie, National, another Knox owned by W. J. Fallon, and a Stearns entered by Kingsley Swan, which captured the contest framed for members of the Long Island Automobile Club and the Crescent Automobile Club.

The timing and scoring were done in a thoroughly competent way by F. L. Burges, G. E. Hand, Arthur G. Inderrieden, W. C. Poertner, H. H. Knepper, Steve Fallon, Leslie A. Davis, Chester L. Darling, and Archie Graham. The device was an automatic trip-wire arrangement which was checked by a particularly perfect telephone system.

Frank G. Webb acted as referee and Fred J. Wagner wielded the flag at the start, assisted by Arthur Burnes. Among the list of judges were the following: William J. Gaynor, Henry S. Brush, Willard M. Bayles, Dayton Hedgess, Charles E. Pickett and Luther H. Chambers.

The most closely contested of all the events was that carded as "8A" for cars with less than 300 cubic inches displacement. In this race five automobiles finished within three seconds of one another. The car that was raced most during the day was the National owned and driven by C. M. Rutherford, an amateur. This car started in both the price and piston displacement classes, the free-for-all and in the amateur event for the Ardencraig Inn cup. In the first it finished a good second to the Knox that was protested, beating two Chalmers cars and a Palmer-Singer. In its piston displacement class it was a close third to the same Knox and the protesting Chalmers entry; in the free-for-all it was seventh, only a trifle over three seconds behind the Knox, which was regarded as the real winner by many of the spectators. Mr. Rutherford drove to a creditable victory in the amateur cup event. In the event of Bell's protest against the Knox being sustained, Mr. Rutherford will have two firsts and a second. The weather was perfect, the course in excellent shape, the police arrangements fine, and the sport was pronounced by many to have been the best of its kind this year. The officers of the club to whom credit is due for the success of the climb are as follows: Daniel M. Gerard, president; Luther H. Chambers, first vice-president; Charles A. Squires, second vice-president; George E. Darling, secretary, and Charles S. Dickerson, treasurer. The consistent performance of all the cars was commented upon. When the Knox, driven by Belcher, won the price classification race for which it was qualified, its time was 30:46; in the displacement classification race which it captured, the same car went under the wire in 28:60. Similarly, Rutherford's National did 30:80, 32:91 and 31:84. The Disbrow Knox did 30:64 and 31:09. Swan's Stearns negotiated two trips in 37:91 and 33:76. In the $800-or-under event, a trio of little "Hups" finished less than four seconds apart. As a rule those cars which were represented in events under both

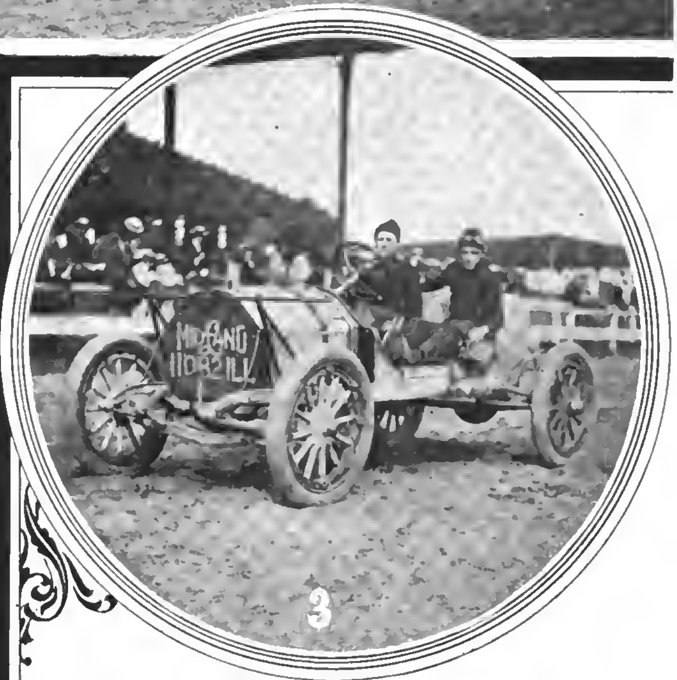
Mt. Vernon Club's Races Furnished Real Sport



1—Lined Up for the Start in the Inter-Club Race

2—The Buicks Had a Successful Day—Three Wins

3—J. M. Boyle's Midland, Second in Westchester Cup Race

UNDER particularly favorable weather conditions, the annual race meeting of the Mt. Vernon Automobile Club was held Saturday at the Empire City race track. There was an attendance of about 1,200, and the program of five interesting events passed off smoothly. The feature of the day's racing was the contest for the Westchester Gentleman's Cup, second on the program. Four elimination trials at five miles preceded the final heat, which was at ten miles. The cars were divided into classes under the piston displacement divisions and the winners in the elimination trials were eligible for the final. In Class C of this event two Buicks were entered and the winner turned up in the car of Russell Smith. Joseph A. Henning protested that Mr. Smith's car was a racing machine and the referee decided to avoid all question by allowing Mr. Henning's car to take part in the final also. The race was won by Spencer Wishard's ancient Mercedes, which has shown sparkling speed in several hill climbs this season. Neither of the Buicks was placed in the final dash.

The last race on the program furnished a bit of sensational work on the part of the winner, Russell Smith's Buick. The race was for the championship of the Mt. Vernon Automobile Club, and Mr. Smith got away flying and was leading at the commencement of the fifth mile when he suffered a blow-out. By a nervy exhibition of strength and cool-headedness, Mr. Smith held the car in the course, and finished first on a flat tire.

The referee was Charles P. Phillips; starter, George A. Lackey; judges, Mayor Edwin Fiske, James M. Gilbert, Frank A. Merrian and Walter F. Stickles. The officers of the club are: Pres., W. H. Mendel; vice-pres., F. A. Merrian, and secretary, L. A. Kissling.

4—Starting the Bunch in the Class A Race

Big Penalties and No Clean

The Cutting, Bisbee Driver, Crossing a Weak Bridge

WICHITA, KANS., June 24—Twelve cars started out and finished in to-day's run of 216 miles from Oklahoma City here and of these twelve seven are Glidden contestants and five are contending for the Chicago trophy. Of the twelve seven made perfect technical scores, these being No. 1, Premier; No. 2, Premier; No. 3, Chalmers; No. 7, Maxwell; No. 100, Moline; No. 103, Lexington, and No. 107, Maxwell.

To-day saw the last perfect road score in the tour pass out of existence when No. 5, Chalmers, driven by W. Bolger, broke a fender iron at 1689 miles from the start at Cincinnati. The fender iron had crystallized and broke with the car traveling at about 15 miles per hour over a smooth road. Bolger immediately stopped and wired it up, being taxed 3 points, or a point a minute for the work. In spite of this the car at present leads in the fight for the Glidden trophy, but the end is not until after the technical examination at Chicago, so it is very problematic as to where the coveted trophy will go.

Four other cars had misfortunes to-day which brought penalties against them. No. 10, Glide, broke a part of the rear-axle housing near Enid, 100 miles out. Another part was secured in Wichita and hurried to the scene so that it was 8 A. M., June 25, before the car checked into here. Its penalty for lateness appears on the chart in this issue.

No. 15, Cino, received 7 points for repairing a broken spring. In the Chicago trophy division No. 101, Moline, took on water seven times because of a leaky radiator and received 21 points. No. 102, Moline, lost 15 points for soldering a radiator leak.

KANSAS CITY, June 25—To-day saw a new record set in National tours in America and in the entire motor world, namely, a tour covering 234.5 miles in one day. The start in to-day's run was made by five cars competing for the Glidden and five for the Chicago trophies, all of which pulled out of Wichita at six this morning.

In addition to the twelve contesting cars in to-day's run there were two press cars, the Halladay and the Great Western. The Halladay had a bad skid on a highly-arched gumbo road 100 miles out and ran into a ditch, springing the front axle slightly, but it was repaired and the car arrived a little behind the contesting cars. The two Cutting cars and the Wescott press car are expected to join the tour here and make the run into Chicago. Yesterday one of the Chalmers confetti cars, which has been lagging behind, after undergoing repairs in Dallas, caught up with the tour and will continue as assistant pilot to Chicago. It is reported here also that the Reo, which has been behind since Hot Springs, will be ready to check out Monday morning on the four-day run to Chicago. Charles F. Van Sicklen, driving No. 106, Falcar, which broke a spring seating on the rear axle entering Dallas, caught the tour Friday night and is running along as a non-contestant. The two Cadillac gun cars are along with the tour, but the Rapid truck has not reported as yet in Kansas City.

Ohio, No. 12, Negotiating a Rocky Ford

Of the twelve contestants nine made the run with clean tech-

Scores in the Glidden Tour

nical scores and three were penalized. No. 3, Chalmers, driven by J. Gardham, received 20 points for replacing a small pin in the gear-shaft connections, requiring 10 minutes for the work. No. 101, Moline, was assessed 74 points for soldering a small leak in the radiator, it requiring one man 74 minutes to do the work. No. 102, Moline, received 4 points, three for taking up some play in the steering gear and one point for loosening it a little.

KANSAS CITY, June 26—To-day has been house-cleaning day with Referee Whiting in the matter of business pertaining to the tour. A protest entered by the Premier company against being assessed three points for taking on water on the ground that the car was acting as confetti car, was settled by the referee allowing one filling of water on this score, but refusing to allow a second one. A protest from the Maxwell entry against being penalized for replacing a spring clip which also served as a part of the shock absorber attachment was withdrawn. A little flurry was caused Sunday morning when Max Parry, of the Parry Automobile Company, appeared before a Federal judge and asked for an injunction to stop the tour on the ground that the referee was refraining from penalizing certain entrants; but the judge refused to grant it, and the matter apparently was dropped. Since then the Contest Board has disqualified the Parry car running as a non-contestant and disqualified the Parry Company from entering sanctioned contests until further notice.

A Welcome Bit of Good Road Near Lake Cormorant

Loading the Cars on the Twice-a-Day Ferry at Helena, Ark.

No. 1 Premier, which is leading in the Glidden half of the contest, lost 2 points for putting on a new fan belt. No. 5 Chalmers, which was leading until Saturday, lost 16 points for tightening a valve cap and adjusting a valve-lifter rod. No. 7, Maxwell, had to fit a new spring clip on the front spring, the clip taken off being one made specially for fitting shock absorbers. Moline No. 101 was penalized 6 points for taking on water twice outside of controls, and No. 102 3 points for the same reason. No. 107, Maxwell, lost 20 points in checking out of the control this morning. No. 2, Premier, received 114 points for replacing a left front spring.

Winton Continues Sixes for 1911

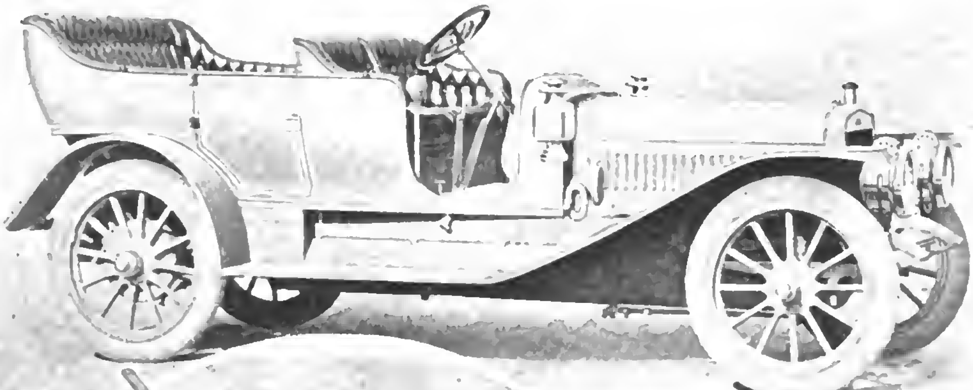
The 48-horsepower self-cranking "Six" without radical change from 1910 practice is tersely described in the Winton literature. The main features are: six-cylinder smoothness; self-cranking; jump spark high tension dual (magneto) ignition system; Winton single nozzle double throttle carbureter; positive water-cooling system; multiple-disc clutch; selective sliding gear; and a conspicuously well-designed screw-and-nut steering mechanism.

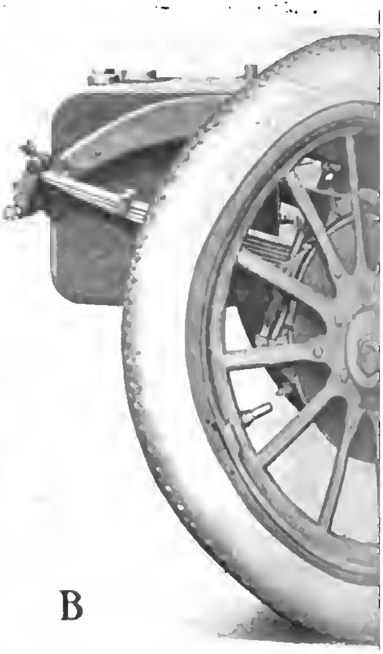
JUST as in the past the Winton output will be confined to continuing along well-defined lines, taking advantage of the experience gained, refining as the situation warrants, and remembering that a well-tried friend, even in the form of a mechanism, has attractions that are not necessarily present in an untried innovation. Under the circumstances it is but a normal expectation when the company comes out with its 1911 announcement of the continuance of the "six-cylinder type of automobile that has been an exclusive product of this plant ever since it was found that this character of equipment was what the company wanted to make and what Winton patrons express a preference for."

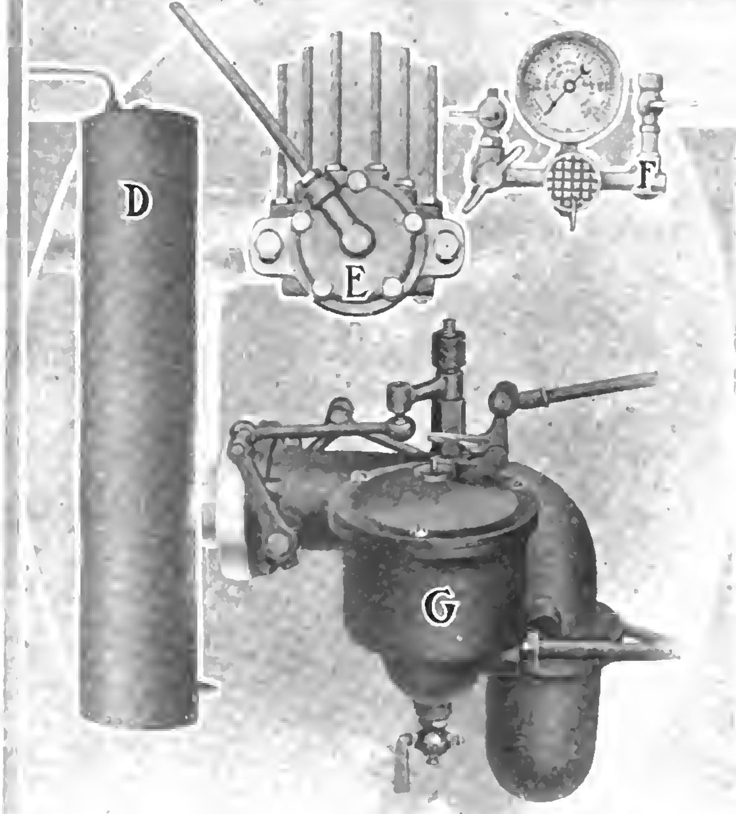
The six-cylinder motor is given an A. L. A. M. rating of 48.6 horsepower; the cylinder bore is 4 1-2 inches, attended by a 5-inch stroke. The cylinder castings are described as a tough character of close-grain gray iron, and the final finish is by grinding. The cylinders are offset from the crankshaft and are submitted to a hydraulic test of 300 pounds per square inch during manufacture. The connecting rods are long, and the stroke being greater than the bore, considering the offset relation, the work that the motor is capable of doing, without undue wear or disagreeable sound, is a fair expectation. The piston pins are made of hardened tool steel, and a great effort is made to balance the reciprocating mass in order that the motor will continue to deliver power in proportion to speed, without exceeding the safe limit from the point of view of extreme fibre strain in the section of any of the parts, even though advantage may be taken of the power which is rendered available by speeding the motor up.

In the Winton plant it is the aim to make all parts interchangeable in order that repair parts may be had at a remote date should the occasion require, with the assurance to the purchaser that the parts will fit in the place for which they are intended when they are received without having to be tinkered with. The positive-cooling system includes a gear-driven centrifugal pump, designed to afford a liberal supply of water, and among the advance features will be found a new design Winton vertical-tube radiator with "gilled" copper tubes. Attention is called to a long filler for the radiator with a notched hard-rubber cap. The radiator fan is gear driven through a friction clutch, and the air supply leaves a margin of safety against undue heating of the cylinders under severe conditions.

A







(A)—General appearance of the 48-horsepower touring car, the roominess of which is shown by dimensions as follows:

Driver's Section of the Body:

Distance from dash to seat, 25 inches.
Width of floor, 37 1-2 inches.
Height of seat from door, 14 1-2 inches.
Measurement of the two seats (each), 17 1-2 x 21 inches.
Seating width at top (outside), 54 inches.

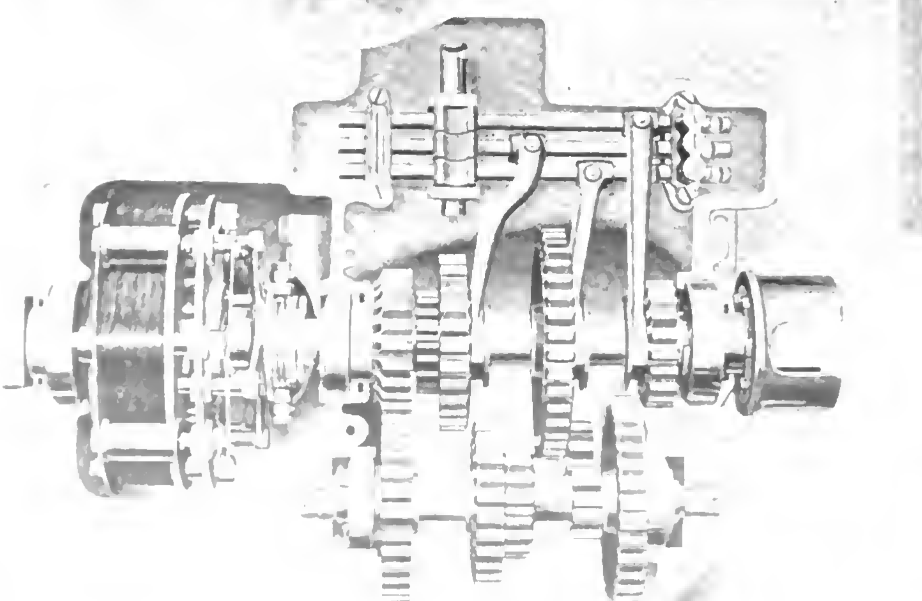
Tonneau Section of the Body:

Distance from front to rear seat, 32 inches.
Width of floor, 37 1-2 inches.
Height of seat from floor, 16 1-2 inches.
Seat measurements, 18 1-2 x 50 1-2 inches.
Seat width at top (outside), 59 1-2 inches.
Width of doors, 20 inches.

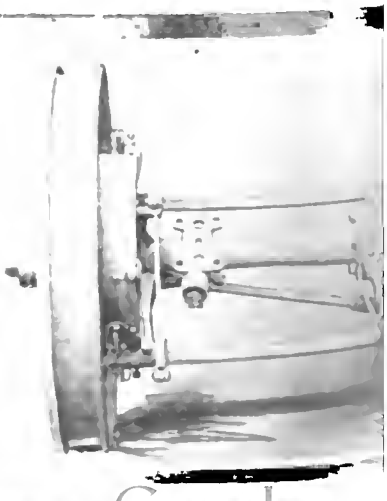
(B)—Long half-elliptic rear springs shackled at both ends; 36-inch tires; wooden wheels; front tires being 36 x 4, and rear 36 x 4 1-2 inches, with Goodrich Quick Detachable Rims; tire inflation is accomplished by special means, in connection with the self-starting mechanism, which includes a tube shown at D, and a self-starting cock F which is located on the dash, and fitted with a pressure gauge. A 22-gallon gasoline tank is shown at the rear end of the chassis, and it contains a 3-gallon reserve supply so arranged that it can only be used after the main supply runs out.

(C)—Right side of the six-cylinder motor showing the position of the magneto, well executed work on the manifolds, secure method of installing the high-tension wiring, and other characteristic features.

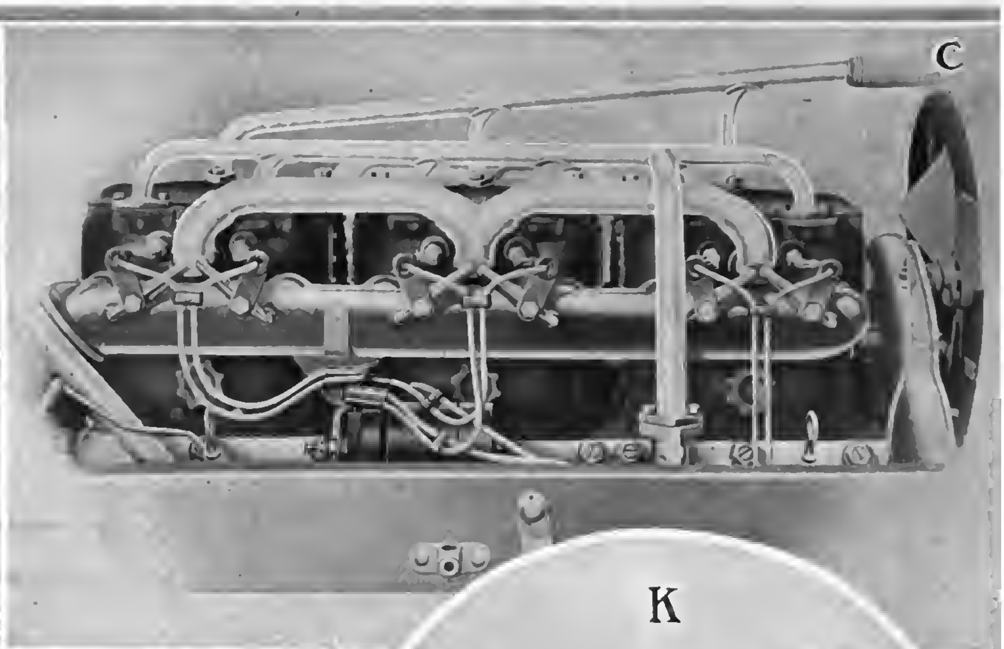
(G)—Winton carbureter of the single-nozzle type, double throttle, with means for combination operation. Gasoline enters the

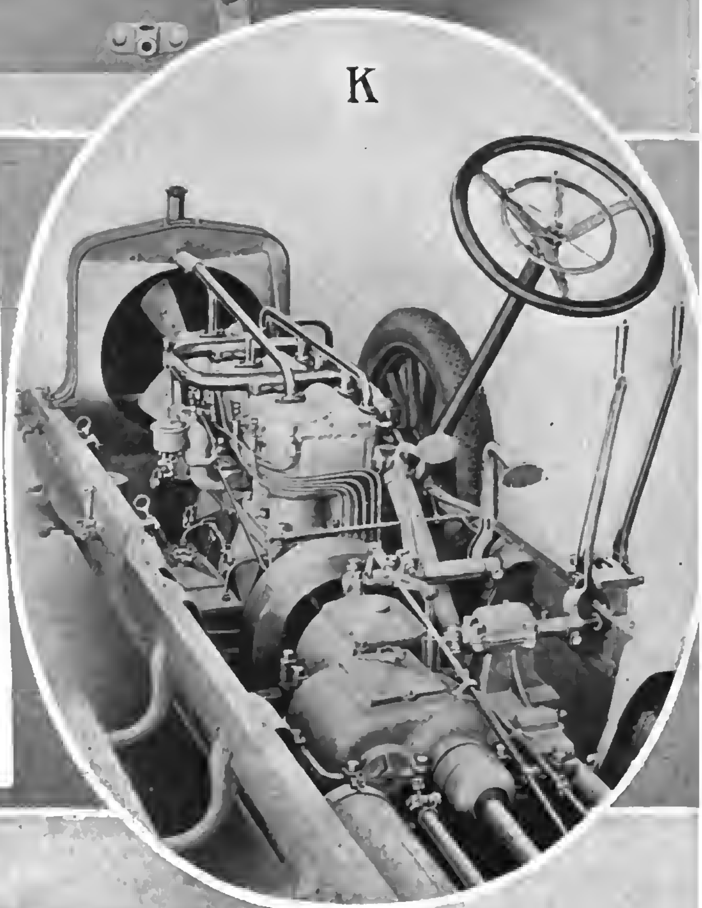


H



Wintcn 1911 Production, Showing the Touring Car With Body Complete, the Six-cylinder Motor, Winton Carbureter, Start





carbureter to the float chamber, passing through a strainer. A hot-air tube is provided to facilitate cold weather starting, and the carbureter is placed on the side opposite to the valves, thus assuring a homogeneous mixture, the distance being sufficiently long to give the entrained gasoline mixing time. A carbureter primer is fastened on the dash.

(H)—Transmission gear and multiple disc clutch with the cover off, affording a clear view of the relations. The speed table of this gear based on 1000 revolutions per minute of the motor is as follows:

Speed Table in Miles per Hour at 1,000 R.P.M.
36-inch Wheels.

Gears	3.69	3.2	2.94	2.64
1st Speed..........	9.33	10.76	11.73	13.01
2nd Speed..........	20.10	23.20	25.27	28.04
3rd Speed..........	29.00	33.47	36.46	40.46
4th Speed..........	36.48	42.10	45.86	50.89

To find the speed at 1500 R.P.M., add one-half.

The multiple disc clutch, which is within the transmission gear housing, is tested to hold 90 horsepower at 1000 revolutions per minute. There are 67 saw-steel friction discs; 33 are attached to the transmission shaft, and 34 to the driving spindles which are attached to the flywheel. The discs revolve in an oil bath.

(I)—Live rear axle, showing the method of trussing, anchorage of the torsion rod, universal joint of the propeller shaft, large diameter brake drums closed in for protection against mud accumulations and an external constricting band brake system, in addition to the in-

Carhartt "Thirty-Five" Introduced

AUTOMOBILE ROW, New York, was entertained on June 22 by R. C. Kelsey, who gave a luncheon at the Plaza Hotel, which was attended by the "Old Guard," which represents the metropolitan press, and a notable sprinkling of automobile experts. After the spread the guests were invited to inspect the Carhartt "Thirty-five," which is an automobile of pretention, just from Detroit, and the staff photographer of THE AUTOMOBILE came away with the illustrations as here reproduced, thinking, perhaps, that autoists prefer to see details of a new car, rather than to admire a perspective:

(A) The rear spring suspension is of the three-quarter elliptic type, with a sufficiency of wide plates secured by double U-bolts on a swivel perch. The axle is of the Timken type of the most approved form, with Timken roller bearings throughout, and the unit system of assembly of the differential gear and bevel drive; the brake drum is of large diameter, and the external constricting band shows clearly in the illustration. The wheels are 34 x 4-inch, artillery type, with 118-inch wheel base, and 56-inch tread.

(B) Left side of the Continental motor, which has an A.L.A.M. rating of 28.9 horsepower. It is of the 4-cylinder type, 4-cycle principle, water-cooled, with a bore of 4 1-4 inches, and a stroke of 4 1-2 inches. The magneto M^1 shows; it is of Bosch Dual type, and the auxiliary coil C^1 protrudes through the dash, bringing the wiring to a point of vantage, so that the electrical installation is substantial and get-at-able. The magneto is driven by the same shaft which meshes with the timing gears in the housing H^2; it passes through the centrifugal pump C^2, and an Oldham joint H^1 is placed between the centrifugal pump and the magneto. In othe respects, the motor is shown so clearly in the illustration, considering its well-known qualities, that discussion will be reserved.

(C) The front construction, considering the part that is most interesting to autoists of discrimination, shows an I-section drop forging in one piece from suitable grades of steel; it is of the Timken make, with Timken roller bearings in the hubs, and the Elliott type of knuckle, including a long through knuckle pin, and means for lubrication. The cross and drag rods are of substantial construction, straight line design, with large diameter balls in the universal joints, means for adjusting and locking, as the importance of the situation demands.

(D) Shows the part of the body, which is of the greatest importance from the point of view of operation. One of the side levers is for the emergency brakes, and the other is used in the manipulation of the Brown-Lipe transmission gear system of the three-speed selective type. The steering wheel, of large diameter, is given an agreeable rake, and the relation between the seat, the wheel, the foot pedals, and the spark and throttle levers is that which accords with the most accepted practice.

The side frames are of the Parish & Bingham make, channel section, and throughout the car, which is an assembled product, each unit is of some well-known manufacture as Gemmer steering gear, etc. The body, as shown at the Plaza, was of the touring type, metal and wood construction, seating five passengers; with hand-buffed leather upholstery, and workmanship to match. The general appearance of the car is highly artistic; price $2,250 with top and accessories.

Digest Along Technical Lines for the Engineer

It is demanded of lubricating oils, that they shall not attack metals; chemical composition must not be altered by temperature; by using ether as a solvent oils may be examined to advantage; oil of resin is difficult to detect; method of locating resinous oil is given; buncombe in the formulæ used in aeronautical discussions; acetylene is promising in the production of synthetic rubber; comparative tests of cooling by water and by mixture with higher boiling point.

It is demanded of lubricating oils that they shall not attack metals, that their chemical composition shall not be altered by high temperature and above all that they shall not contain oil of resin. For the latter requirement no other reason is given than that perhaps the oil of resin is more volatile than the rest and may contribute to "cracking" as well as increase the total consumption. Its density is however, 938, while the pure mineral oils with which it is found mixed have a specific gravity of only 900 to 925. In practice scarcely any other means are employed for testing lubricating oils than to use a sample of one for a day's journey, to force the speed of the vehicle and to examine in the evening the metallic surfaces and the residues. A chemical test has fewer inconveniences. The lubricating oils usually belong to the paraffine group of petroleum distillates. They are always thick and brown. but of a shade varying with the angle of the light. They get thinner with heat and are finally evaporated into thick fumes, as one may observe by heating a drop on a piece of paper over the flame of a candle. They are easily soluble in ether and this permits a ready examination for foreign corpuscles, and gives a chance for dosing them chemically. Every insoluble ingredient is at least suspicious and everything infusible is harmful. Only graphite, among infusible ingredients, is tolerated on account of its lubrifying properties. But one should be circumspect with regard to graphite, partly because there are gritty and impure brands in the trade, and partly because this substance lends itself to other adulterations. At any event, the adulteration with oil of resin remains always the most difficult to detect, and it is a practical method to this end which is most required. The method proposed rests upon the colored reaction for resin given by Mr. Sans of the Laboratory for Resins at Bordeaux (Annales de chimie analytique, 1909; page 100). The author describes it as follows: "If a very small quantity of resin is added in a test tube containing one or two cubic centimeters of neutral sulphate of methyl, and the tube is slightly heated, there is observed a coloration passing from rose to violet and deep violet and which disappears when the temperature is raised, leaving only a slight brownish shade."

Under similar conditions slight traces of oil of resin give practically the same reaction, without reaching the deep violet, however. If the oil is emulsified in water, the reaction is plain without heating. But if it is dissolved in alcohol, no coloration appears. To apply these properties to a test, one proceeds as follows: Pour 3 to 5 grammes of the suspected oil in a tube, and on top thereof about five times as much of 60 proof alcohol: close with a stopper and heat in a wet-bath to 40 to 50 degrees centigrade, so as to render the oil more fluid, and shake until an emulsion is formed. This is now cooled in water, and fatty globules separate themselves from the medium. By turning the tube gently up and down three or four times, the globules are made to form a single mass, which rises to the top or sinks to the bottom of the liquid, according to the specific gravity of the oil. The whole contents are now thrown on a filter, and the liquid runs off rapidly and is received in a capsule, which is heated in a wet-bath until the alcohol alone has disappeared, and the residue is then allowed to cool. If then, into this water without alcohol, there is dropped sulphate of methyl the appearance of red color shows the presence of oil of resin. The color vanishes rather quickly after the first few drops, but by adding more, up to 2 to 3 cubic centimeters, the color reappears with increased intensity and more lasting. It should be remembered that there will be no reaction with alcohol 90 to 95 proof. Even with the use of 60 proof alcohol it is reduced, and it may not appear if the desiccation of this alcoholic extract is complete. The use of 60 proof alcohol is necessary so as to avoid any dissolution of the paraffine oil, and the preservation of the water in this alcohol, after one-half its volume has been evaporated, is required to get the most sensitive reaction. Synthetic experiments with this method have shown that it will detect an admixture of one per cent. or even less of resin oil to a lubricant.—*Les Sports*, June 8.

"At the present stage of hydrodynamics, direct and quantitative application of theoretic knowledge to aeronautic construction problems is rarely possible. Only qualitative explanations of a general nature and experimentally ascertained figures are in question." In other words, without circumlocution, most formulas relating to flight problems and pretending to give mathematical relations of the forces involved in atmospheric thrusts are as yet buncombe. From an article on the present stage of the "science of aviation," by Diplom-Engineer F. Bendemann in *Zeitschrift des Vereines Deutscher Ingenieure*.

Acetylene is one of the substances promising best results in the production of synthetic rubber, and there is some hope in this fact for the languishing calcium carbide industry.—*Engineering* (London), May 13.

A cooling medium boiling at 170 degrees centigrade instead of 100 degrees, as water, and suitable for use in the water-jackets of automobile engines, has been devised by Mr. Boursin and tried out in a long series of experiments at the Conservatory of Arts and Trades. For example, a motor was first operated cooled to an exterior temperature of 168 degrees by means of Boursin's mixture, and a quarter hour afterwards the same motor was cooled with water. Observations were first taken after one hour of running. The average r.p.m. was 1130, the power 4.22 hp., the gasoline consumed in two hours 3.054 kilograms. The metal radiator maintained a constant temperature of 40 degrees. With water in the jacket, observation was commenced when the water had reached 93 degrees. The chief of the laboratory advanced the ignition two notches. The r.p.m. was 1160, the power 4.25 hp., the consumption of gasoline 3.557 kilograms. With about equal power the gasoline consumption with water cooling had increased 16 per cent. At a renewed trial with the new cooling mixture, 3 millimeters was added to the lift of the exhaust valves, and the gasoline consumption went down to 2.700 kilograms, while the power was somewhat increased. From these tests one may draw some conclusions. The temperature of the exhaust is raised, fewer calories are absorbed by the walls and the efficiency is increased. Hence, to get all the advantages offered by using a cooling medium of high boiling point, reduce the length of the suction stroke while keeping the compression unchanged, and the fuel economy will be improved. Or, if it is desired to increase the power at equal fuel cost, increase the areas of the ports. In fact, ports sufficient for a water-cooled motor are no longer sufficient for a motor working at higher temperatures, whether through air-cooling or use of a cooling medium like Boursin's. In the complete reports of this investigator, a theoretical accounting for the various heat losses under the different conditions is promised.—*La Vie Automobile*, June 11.

Helpful Hints for Those Who Drive

Y an automobilist has wished for a self-starting evice, and has scoured the market in search of one, success. Similarly there are many who desire a of pressure, such as is not supplied with the car. ınt can be supplied by any handy man who can select s and fit them to his car in a proper manner, a contract early any real American would undertake.

ıaterials necessary to make and fit to the car the source ure supply shown in the appended cut are few, consist- . stout tank of perhaps two to three cubic feet capacity. .ion to this, there is needed a stop cock, a non-return drain cock for the tank, a gauge, and the necessary of heavy copper tubing of 1-4 inch or smaller diameter. p cock is screwed into the top of the cylinder, and a ds from there to the tank, located in any suitable and :nt place. Just ahead of the tank is placed the non- valve, to prevent the pressure from escaping back to nder during the suction and other strokes when the is likely to be lower than that in the tank. The drain

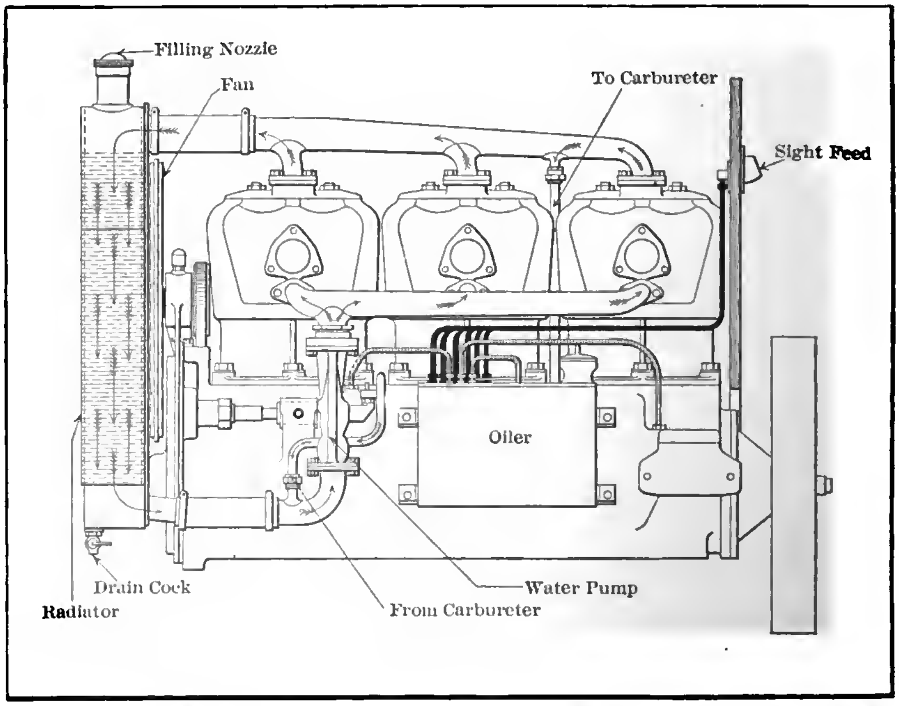
be fitted to one end of the tank, at the lowest point, so as to draw water of condensation.

another point of the tank the gauge is led, and, also, the sup- If the pressure is to be used for tires, for cleaning off dust, or for the horn, the pipe would naturally ward to somewhere near the dash- On the other hand, if the automo- ambitious and wants to fit a start- ce, the supply pipe should lead to a or placed directly upon the dash. pressure gauge, although shown ı the tank, would preferably be ɔn the dash and fastened to it, this nly a matter of piping.

motion takes place when relative ·e lacking in harmonious adjust- The effect of lost motion in any is usually to rack the machine ; long before it would wear out if ıttention were given to the align- ıbrication, and adjustment of its Where there is lost motion there is ınger; excessive wear, noise, and ıcy are its accompaniments; and many a serious accident has been traced directly to neglected lost motion in the steering gear. "Why is the repair shop so very prevalent?" The answer may be, "Chiefly because of lost motion." The life and safety of any bearing decrease as the lost motion increases. Therefore, do not neglect lost motion.

It frequently happens that a horn becomes dented. To restore it to its normal shape it is usually sent to a musical-instrument maker or to the manufacturer of the horn, which is not only expensive but also involves considerable loss of time. By the following method dents can be removed from the "bell" of a horn in the garage or at home. The materials necessary are a length of strong half-inch wire, solder, a blow torch and vise. The wire is bent into a loop of about the size of the dented portion at one end and is then soldered to the dented portion. The wire is then gripped in a vise or wrapped around another piece, to prevent the wire running through the jaws of the vise. The horn is now grasped with both hands, and a series of gentle pulls in the direction of the arrow will bring the bell to its original contour. The solder is then melted with the blow torch, when the wire loop comes away, and the operation is finished, except for polishing.

Amateurs really should learn to take care of the component parts of the water system. The diagram below shows the whole water system of a well-known car, in which the water is filled into the usual filling cap, flows downward and back to a centrifugal pump, is there projected up to the bottoms of the cylinders, whence it carries off the heat, loses in specific gravity, rises and flows out through the upper water pipe to the top of the radiator, where it is cooler, and starts over again. In this system, the two hose pipes at the top and bottom of the radiator should be frequently inspected, and often replaced, this being a very small expense. The gaskets at the junction of the upper and lower pipes with the cylinders, six in number in this case, should also be inspected and replaced frequently, while the small pipe shunt to the carbureter must be taken off and cleaned out at frequent intervals; it easily fills with slime and sediment.



Complete Water System of Thomas Six-Cylinder Car, Showing Where Care Is Needed

Rejuvenating the Old Automobile

By G. J. MERCER.

> Illustrating a modern fore-door type of body as it would appear on a Chalmers "Thirty" touring car, giving all information required by a body maker and showing how the body will appear when completed. In this case the side lever for sliding the gears comes inside of the fore-door on the right-hand side of the car, and the emergency brake lever falls to the outside.

ial specified is 16-gauge sheet aluminum over the autoist to utilize the fore-doors in periods of inclement weather and to avoid the couped-in feeling during periods of calm.

Referring to Fig. 11 the dotted lines of the speed-change lever indicate how it must be bent in order that it will pass through an opening of the body to the inside at a point above the quadrant. In this car the quadrant is not only high up but falls to a considerable distance outside of the line of the chassis frame. This necessitates a rather deep cut in the body, and in order to create a somewhat better impression than would otherwise obtain, this cut may be housed over. The throw of the lever is relatively short, which is a fortunate circumstance, since it reduces the dimensions of the housing and makes it possible to consider having the side

. The pillar to form the doorway as shown U-shaped bent wood piece, framed against the and to the underbody. The pillar is continuous stance up the front of the door, and the metal ooved into the same, rather than to have it ıtside. At the bottom a horizontal framing piece en the pillar and the dash. It is also necessary ter moulding into the pillar, when the latter is underbody. The doors are hinged, and it is ıt they be swung in a substantial manner, al- unity will be offered to select the character of permit of detaching the doors at will; this is ınd it offers the advantage of permitting the lever for the sliding gears fall to the inside. It is a much more convenient arrangement.

Rapid System of Finishing Bodies

Clean surface thoroughly, apply primer, work to smooth finish, sandpaper surface ending with No. O; dust off. On the third day apply opaque color, then ground-work color; when dry apply coat of glaze, rub lightly with a roll of broadcloth dipped in water, and No. OO pulverized pumice stone to kill gloss. Apply coat of elastic rubbing varnish, then rub with pumice stone and water. About the eighth day, apply coat of clear elastic rubbing varnish, slick down with pumice stone and water, wash up and finish with a rich full body varnish.

Vulcanizer Thermometers Frequently Deceive

By JAMES S. MADISON.

THE manufacture of thermometers for use in cases where accuracy and precision are required has reached a high state of development. Thermometers used for purely scientific purposes leave small room for improvement. This is especially true of instruments made by a reliable manufacturer, and afterward standardized and certified by the Reichs Anstalt in Germany, or by the United States Bureau of Standards at Washington. Such thermometers will give the exact temperature through a range of 100° or more, with a variation of only one-tenth of a degree. Because of the care with which they are made, calibrated and tested they are naturally expensive. But the ordinary thermometers, certainly the cheaper varieties, are never accurate and should always be tested before using. The small tube thermometers used in connection with the different forms of vulcanizers should be tested, since many of them are so inaccurate as to lead to disastrous results.

One of my acquaintances recently purchased an electric vulcanizer. He used it to repair cuts in his casings, etc., each time carefully following the directions of the manufacturer, as to the time and temperature of heating. He was particularly cautious not to allow the temperature to go above the danger point, 265°-275°, as stated in the directions for vulcanizing. Several days after he noticed that the casing upon which he had been working was developing an incipient blow-out in three different places. Not only was the rubber tread burned, but the fabric was also burned and had begun to bulge out, and would have blown out in a very short time if the casing had not been removed from the rim. An examination showed that it was ruined.

The thermometer in question and one belonging to the writer were taken to the laboratory of a neighboring college and tested by comparing with a standard thermometer. The test was carried out as follows: The standard and the two vulcanizer thermometers were suspended in a glass beaker nearly filled with cylinder oil. This was supported on a wire gauze over a tripod and heated with an ordinary Bunsen burner. The readings were taken at 250°, 265°, 275° and 280° with the following results:

Standard F°	A F°	B F°	Error A F°	Error B F°
250.	267.0	268.0	+17.0	+18.0
265.	283.5	282.0	+18.5	+17.0
275.	293.0	290.0	+18.0	+15.0
280.	302.0	302.0	+22.0	+22.0

From these figures it is obvious that when the thermometer read 275°, the temperature was at least 18° higher. It is also obvious that one should not rely upon the ordinary thermometer implicitly. It is also important to remember that even if the thermometer be approximately correct, it will not necessarily give a reading of the right temperature of the vulcanizer at the point of contact between it and the tire. In some forms of vulcanizers the thermometer is supported by a shoulder at the extreme edge of the instrument. In view of its distance from the center, and the quantities of heat that are lost by radiation, etc., the temperature actually shown by the readings is, in all probability, lower in every case than the real temperature at the center of the vulcanizer, the usual point of contact between it and the tire. If the thermometer were placed at the center, it would not be at all surprising to find that it would read from 10°-15° higher than it does at the edge.

Importance of Proper Timing Overlooked

WHEN an automobile has been in service for awhile the timing falls away from its correct position a little in the better types of motors, and to a considerable extent in the average of them. Some motors are provided with systems of adjustment so that the re-timing problem is reduced to a minimum, but the autoist who undertakes to time his own motor without understanding the intricacies of the problem has one chance in his favor and 99 against arriving at the right conclusion. Since two-cycle motors cannot be timed after they leave the maker's hands the discussion here will be confined to the four-cycle types of motors, and referring to Fig. 1, which is a diagram of the four-cycles, it will be observed that the wavy line which starts at O, which is the atmospheric line (14.7 pounds per square inch at the sea level), sweeps upward during the expansion stroke, crosses the atmospheric line at the end of that stroke, falls below O during the back pressure period, and if the muffler is of the ejector type rises above the line approaching the end of the exhaust stroke; but when the suction stroke comes on, a depression is generated which represents a loss in the total power summation, which depression usually reaches O at the end of the suction stroke and is followed by the compression stroke, which represents a power loss throughout, varying with the compression. This curve is made without considering the increase in pressure which is due to ignition and expansion, so that the pressure in pounds per square inch, as shown, is that which would obtain were the motor run as a compressor in the absence of the ignition phenomena.

The power which may be taken from a motor will be indicated by the area of the enclosure embraced by the atmospheric line at the bottom and the upward sweeping curve, starting and ending at O on the expansion stroke, plus such portions of the curves of the exhaust, suction and compression cycles as may sweep above the zero line, diminished by the areas represented by the curves which sweep below the line in the exhaust, suction and compression cycles. The great problem under the circumstances lies in so timing the motor

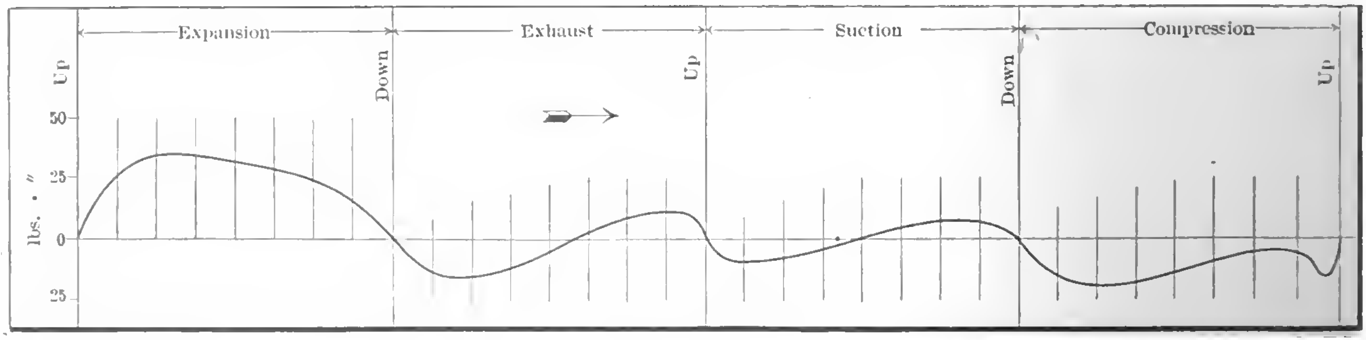

Fig. 1—Curve plotted to show the compressor action of an automobile motor, and the variations of pressure during the 4-cycles

that it will give the greatest possible power value during the expansion stroke and a minimum of the pumping losses during the exhaust, suction and compression strokes.

Fig. 2 shows the markings on the flywheel of a motor, which will enable the autoist to fix in his mind the timing of the valves. as it is referred to in the tabulations here given, and in the table the timing relations are given for several motors, so that the autoist will be enabled to select a timing which will accord with the speed of the particular motor he desires to doctor, taking into account the fact that a high-speed motor should be timed somewhat differently from a motor which runs at a low speed.

SATISFACTORY TIMING FOR GIVEN TYPES OF MOTORS

Name of Motor	Lead of exhaust opening	Lag of inlet closing	Ignition advance	Lag of exhaust closing	Lag of inlet opening	Speed at full power
Charron	41	0	var.	0	1	1,100
Gregoire	53	0	var.	0	5	1,200
Hotchkiss	44	33	var.	10	17	1,300
...ter	40	40	var.	0	0	1,400
Darracq	48	30	21	0	0	1,500
Renault	32	26	33.5	10	23.5	1,600
Sizaire	44	37	var.	0	15	1,700

The motors as here selected give a range of speed from 1,100 to 1,700 revolutions per minute, and the timing, which seems to give the best results in view of the respective speeds. In two of the cases the spark advance is fixed, and the range between the two is very great, considering the speed changes, which goes to show that a wide range is permissible.

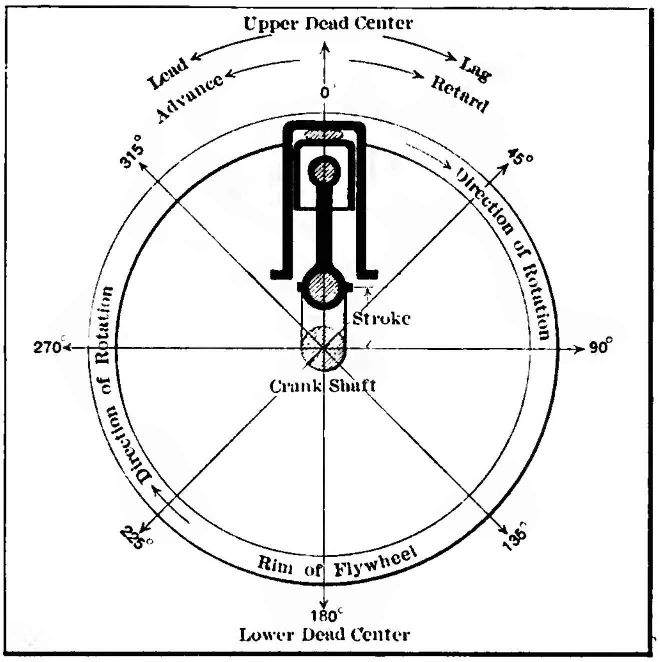

Fig. 2—Showing markings on motor flywheel, enabling autoist to gauge timing of the valves

Some of the Reasons for Frequent Valve Grinding

The aim of this article is to state why valve grinding is necessary, there being two reasons, one of which is due to improperly operating the car, and the other is the result of poor design of the motor. The illustrations are made comparative to help bring out the important points to be made.

POPPET types of valves were adopted for gasoline motors because they afford the requisite qualities, under severe conditions of service, which will permit them to do the work required of them for long periods of time, with little or no attention on the part of the operator, but when they have to be overhauled no great skill is required in the process. The best results come if the valves are properly fashioned, and if the materials employed in their construction are those which will withstand wide variations of temperature and a considerable amount of shock. The material must also be close grained in order that the valve seat will grind to tightness.

Fig. 1 shows a type of cone-seat valve, which is used, perhaps, more than any other type, but in this case the head is attached to the stem with little or no fillet, and the result is that the head and the stem do not hold to their right angle relation after the valve heats up, because the small amount of metal at the junction of the stem with the head is insufficient to serve as a conducting medium for the heat which is picked up by the head but which must be conducted away by the stem. The measuring instruments which are placed alongside of the valves in this figure show a gap at the lower portion of the seat on one side, and at the upper portion at the other when the bases of the instruments are placed firmly against the stem If the two protractors as placed show that the bevels are not at the same angle it is a self-evident fact that with the stem in its guide, if the head is not at right angles, as it will not be when it is as shown in Fig. 1, then the valves cannot be ground to tightness at all. This is frequently the case, and if a little Prussian blue is placed on the valve seat and it is smeared around evenly, it will then be found upon inserting the valve in its guide and giving it a twist that the blue will not remain evenly over the surface but will scrape off at one point of contact. It will not be necessary to use a protractor to locate this difficulty under working conditions, but it may be necessary to replace the type of the valve which has no fillet between the head and the stem, and substitute one of the design as shown in Fig. 2, which has a liberal fillet at the junction of the head with the stem, and which shows no gap when the two protractors are placed so as to show the angle of the bevel as it relates to the stem.

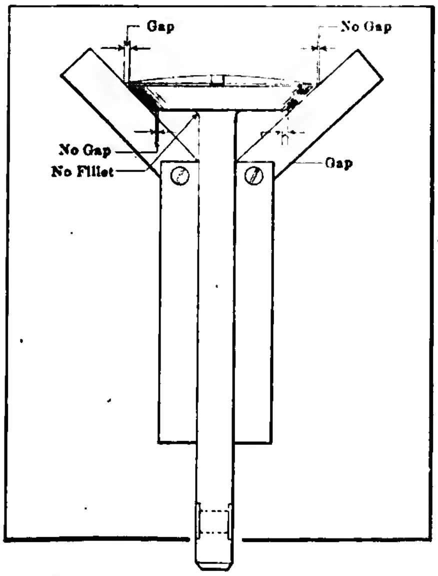

Fig. 1—Cone type of valve without a fillet between the head and the stem which warps when heated.

In some types of motors the valves are provided with flat seats as shown in Figs. 3 and 4. Warping will take place in precisely the same way as before stated, and referring to Fig. 3, it shows how the head will be off of the seat at one point in the diameter when it is on the seat at the other point, if the design does not include a fillet. Fig. 4 shows the flat-seated valve with a liberal fillet and it will be easy to

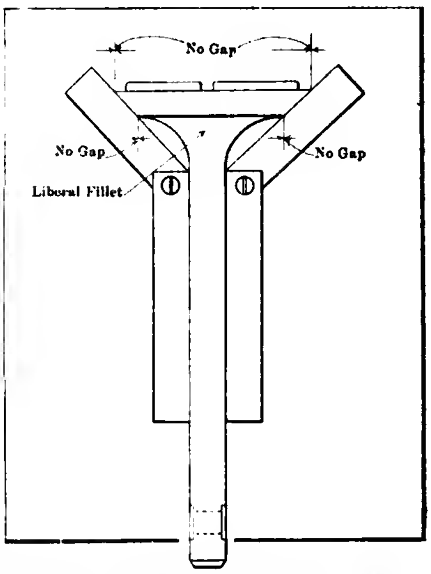

Fig. 2—Cone type of valve with a liberal fillet between head and stem which prevents warping with heat changes

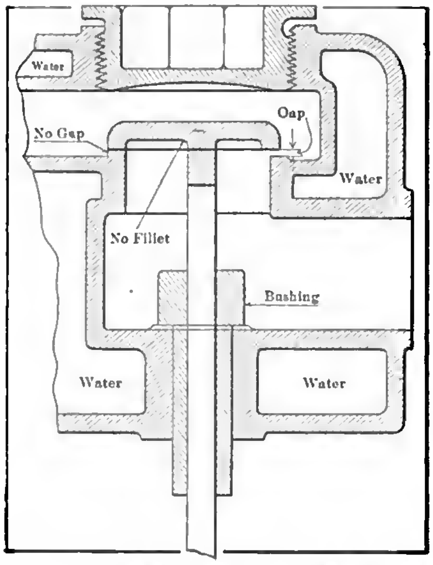

Fig. 3—Flat seat type of valve without a fillet, which warps when heated

understand how the large section of metal at the junction of the stem with the head will serve to conduct the heat from the head through the stem to the bushing or guide, from there through the section of the casting, and finally into the water of the water-jacket. If the stem does not fit quite closely in its guides the air gap resulting will retard the flow of heat from the stem to the water in the water-jacket, and the difference in temperature will be somewhat greater in consequence. Under such conditions, if the fillet is neglected, the chance of maintaining a tight relation of the valve to its seat will be reduced to a minimum.

If, in any given motor, the valves, after they are ground in, do not stay tight for a reasonable length of time it will be a fair assumption that the valves are not properly designed, or that the operator runs the motor on a retarded spark. There may be contributory reason in addition to either of these, but running on a retarded spark, if the valve is properly designed, induces excessive heating and prolongs the time when the red-hot gases are sweeping over the surfaces of the seats so that pitting results and this character of leaky-valve trouble will come independent of the design of the valve, excepting that some kinds of valve metal will stand more abuse than others.

In the selection of metal for valve heads 35 per cent. nickel-steel with a low carbon content serves extremely well, although it is claimed by some designers that this metal is not good to use in the stem, and they, when they use high nickel-steel heads, make the stem of mild steel and rivet one to the other. Another type of metal which was first brought out in Panhard cars and which works with good satisfaction, is a high carbon-steel product with the carbon ranging between 110 and 115 points with other components to match, excepting that the metalloids should be low, and it is probably an advantage to fabricate this steel in relatively small heats by the crucible process.

In addition to these types of valves, some very satisfactory performances are realized by using a cast gray iron head riveted to a mild steel stem. In this type of valve, the mild steel stem has good value from the bearing point of view, and it has been found in practice that cast gray iron not only serves well as the valve seat, but it is equally efficacious from the seat point of view when used as a valve head. Valves of this character are easily ground in, and they have the virtue of serving without pitting, a not uncommon difficulty in valves employing other materials. This pitting question is quite prominent in some of the types of nickel-steel.

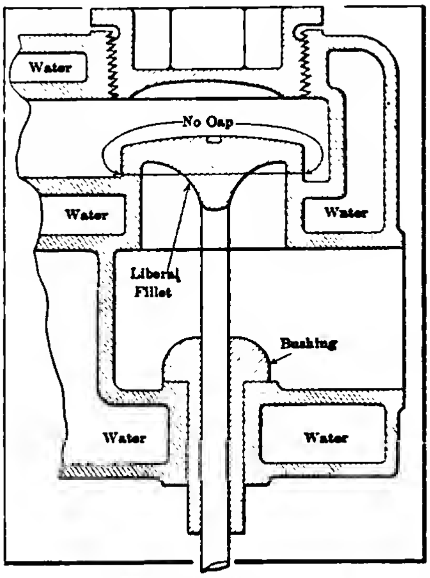

Fig. 4—Flat seat type of valve with a liberal fillet between the head and the stem, which prevents warping under heat changes.

Testing Steel—For Impact, Bending, Etc.

By BERTRAM BLOUNT, W. G. KIRKALDY and Capt. H. RIALL SANKEY.

(Second Installment)

In the present installment is given a list of the representative types of steel tested in accordance with the British standard specifications of each type, together with a short epitome of the respective specifications.

AMONG the makers who supplied various types of steel for testing purposes, as mentioned in the last installment, were the Parkgate Iron & Steel Co., Messrs. David Colville & Sons, Messrs. Taylor Bros. & Co., Messrs. Walter Scott, Messrs. Thos. Firth & Sons, Messrs. Cammell, Laird & Co., the North Eastern Steel Co., Messrs. Dorman, Long & Co., and the Patent Shaft and Axletree Co.

Representative types of steel were chosen, and the following is a complete list, together with a short epitome of the respective British Standard specifications:—

1. Marine Boiler-Plate suitable for shell—British Standard Specification for Structural Steel for Marine Boilers (Report No. 14: Revised March, 1907: breaking stress 28 to 32 tons per square inch, elongation on 8-inch gauge length not less than 20 per cent.
2. Marine Boiler-Plate suitable for combustion chamber—British Standard Specification for Structural Steel for Marine Boilers (Report No. 14: Revised March, 1907): breaking stress 26 to 30 tons per square inch, elongation on 8-inch gauge length not less than 23 per cent.
3. Locomotive Boiler-Plate suitable for portions not exposed to flame—British Standard Specification for Steel for Plates, Angles, etc., and Rivets for Locomotive Boilers (No. 16 of Report No. 24): breaking stress 26 to 32 tons per square inch, elongation on 8-inch gauge length not less than 22 per cent. Not more than 0.05 per cent of sulphur or of phosphorus.
4. Locomotive Boiler-Plate suitable for portions exposed to flame—British Standard Specification for Steel for Plates, Angles, etc., and Rivets for Locomotive Boilers (No. 16 of Report No. 24): same as for item 3.
5. Forging—British Standard Specification for Steel Forgings for Locomotives (No. 8 of Report No. 24): Class B, breaking stress 25 to 32 tons per square inch, elongation on a test-piece 0.798 inch diameter and 3-inch gauge length not less than 27 per cent. with 25 tons per square inch breaking stress, and not less than 20 per cent. with 32 tons breaking stress. The sums of the breaking stress and of the elongation not to be less than 52.
6. Forging—British Standard Specification for Steel Forgings for Locomotives (No. 8 of Report No. 24): Class D, breaking stress 40 to 45 tons per square inch, elongation on a test-piece 0.798 inch diameter and 3-inch gauge length not less than 20 per cent. for 40 tons breaking stress, and not less than 15 per cent. for 45 tons breaking stress. The sums of the breaking stress and elongation not to be less than 60. Elastic limit not less than 50 per cent. of the breaking stress.
7. Locomotive Axle—British Standard Specification for Locomotive Straight Axles (No. 2 of Report No. 24): breaking

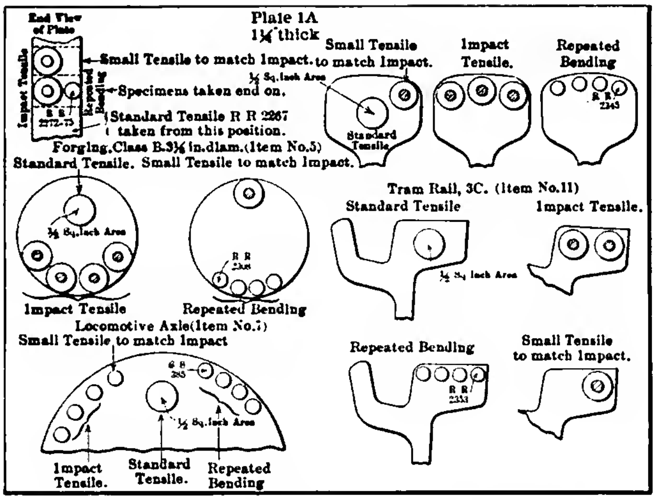

Fig. 1—Sketches showing position of test specimens

stress 35 to 40 tons per square inch, elongation on test-piece 0.798 inch diameter on 3-inch gauge length not less than 25 per cent. with 35 tons breaking stress, and 20 per cent. with 40 tons breaking stress; the sums of breaking stress and elongation not to be less than 60. Elastic limit not less than 50 per cent of the breaking stress. Not more than 0.035 per cent. sulphur or phosphorus.

8. Wagon Axle—British Standard Specification for Carriage and Wagon Axles (No. 3 of Report No. 24): breaking stress 35 to 40 tons per square inch; elongation on test-piece 0.798 inch diameter and 3-inch gauge length not less than 25 per cent. with 35 tons breaking stress and 20 per cent. with 40 tons; the sums of breaking stress and elongation not to be less than 60. Elastic limit not less than 50 per cent. of breaking stress. Not more than 0.035 per cent. sulphur or phosphorus.

9. Bull-Head Rail, 95 lb. section, as supplied to the North Eastern Railway. Basic Bessemer—British Standard Specification and Sections of Bull-Head Railway Rails (Report No. 9; Revised July, 1909): breaking stress not less than 40 and not more than 48 tons per square inch. elongation on test-piece 0.798 inch diameter and 3-inch gauge length not less than 15 per cent.

	Per cent.
Carbon	0.35 to 0.50
Manganese	0.70 to 1.00
Silicon ....not to exceed	0.10
Phosphorus ...... " " "	0.075
Sulphur .... " " "	0.08

10. Bull-head Rail, 90 lb. section, as supplied to Indian Railways. Acid open hearth—British Standard Specification and Sections of Bull-Head Railway Rails (Report No. 9: Revised July, 1909): same as for item 9.

11. Tramway Rail, 95 lb. section—British Standard Specification for Tramway Rails and Fishplates (Report No. 2): breaking stress not less than 40 tons per square inch, elongation on test-piece 0.798 inch diameter and 2-inch gauge length not less than 12 per cent.

	Per cent.
Carbon	0.4 to 0.55
Manganese	0.70 to 1.00
Silicon ....not to exceed	0.10
Phosphorus. ...... " " "	0.08
Sulphur .... " " "	0.08

12. Tire—British Standard Specification for Carriage and Wagon Tires (No. 5 of Report No. 24): Class C, breaking stress 50 to 55 tons per square inch, elongation on test-piece 0.564 inch diameter and 2-inch gauge length not less than 13 per cent. with 50 tons breaking stress, and not less than 11 per cent. with 55 tons. Not more than 0.035 per cent. sulphur or phosphorus.

13. High-tensile nickel-chrome steel for automobile parts.

The location of the various test-pieces was selected with a view of giving the best practical information in respect of the use of each type of steel, and in this matter the long experience of Messrs. Kirkaldy & Son was of the utmost value. Care was taken so as to record and identify each test-piece that its original position and orientation in the sample can be determined. Fig. 1 shows the positions from which sample test-pieces were taken.

Forced Lubrication—Trend in English Practice

By R. K. MORCOM

(Fourth Installment)

THE make-up in the experiment in forced lubrication mentioned in the last installment was by a small scoop pump feeding the proper quantity into the crankcase in the usual way. The oil after use was black in color, and smelt of petrol. Tested for viscosity it gave the curve X (Fig. 21) on a Redwood viscometer. Its flash point, open test, was 214 deg. Fahr. against 435 deg. Fahr. On distillation at 300 deg. Fahr. 1½ per cent. of petrol came over. After distillation the flash point was normal at 435 deg. Fahr. The oil was still dark in color, but appeared to be a satisfactory lubricant. On burning the amount of ash was very little over normal.

On the subject of oil the information of Table A is not very full. The general consensus of opinion is in favor of a high quality mineral oil of high flash point, well maintained viscosity, and low cold test. The viscosity curve of a satisfactory oil called "SSL" is given in Fig. 21. This oil has a flash point of 420 deg. Fahr., and is fluid at low temperatures. It is probably advisable to use a heavier oil in summer than winter.

There are many satisfactory oils on the market, but also unfortunately many bad ones. Most makers will give sound advice as to the oil which suits their make of engine.

It would have been interesting to collect some figures of temperature normal to different engines after a long run, and it might be found that an oil cooler would be advantageous. This is fitted to steam engines for hot climates, or long continuous running, with beneficial results, and is invariably a part of a steam-turbine equipment.

The question of wear has not been considered, as the author has been unable, for obvious reasons, to collect reliable figures on this point. A car originally lubricated on the trough system has certainly run better, and shows less signs of wear, since forced lubrication was fitted; but one instance is not of much value. Many instances, however, of steam engines with forced lubrication could be given in which the wear has been infinitesimal.

An endeavor has been made to touch on the various points necessary to ensure good working of the system, and the conditions which exist. It is easy to meet these conditions, and when met it will be found that the forced lubrication system brings about high mechanical efficiency, quiet running and absence from wear.

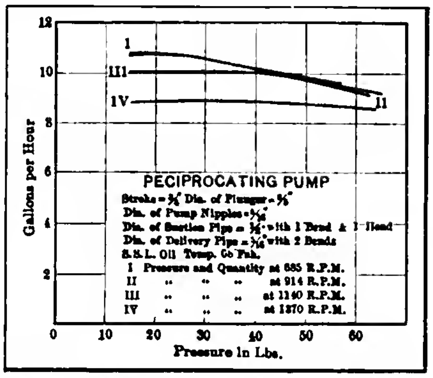

Fig. 17—Capacity of plunger reciprocating pump with oil at 68 deg. Fahr.

Peculiarities of Modern Non-Charring Brake-Linings

TRAINED in the belief that the brakes, to be efficacious, must be so designed that the shoes will press against the drum-face with considerable force in pounds per square inch, it is with much difficulty that men who work on this character of undertaking frequently make the mistake of designing so that the result of their handiwork falls below the possible realization. To be more specific, let it first be stated that the coefficient of friction, as it is usually stated for the several grades of materials, does not afford the true measure of the normal expectation under working conditions.

The coefficient of friction of the several materials, as it is usually determined, represents the multiplier which is obtained by dividing the whole force of friction by the normal pressure; hence, in brief language, the coefficient may be defined as the unit friction due to a normal pressure of one pound, and for the various materials, while it is not constant by any means, even for the same materials rubbing on each other, it may be approximately stated as follows:

APPROXIMATION OF THE COEFFICIENTS OF FRICTION

Friction Materials	Coefficient
Cast iron on oak	0.49
Wrought iron on oak	0.62
Cast iron on cast iron	0.15
Wrought iron on wrought iron	0.14
Brass on iron	0.16
Brass on brass	0.20
Wrought iron on cast iron	0.19
Leather on wood	0.49
Leather on cast iron	0.28
Cast iron on cast iron, greased	0.10
Cork inserts on cast iron	0.35
Cork inserts on cast iron (lubricated)	0.23
Asbestos friction fabric on cast iron	0.25

In the utilization of these coefficients, in the absence of experience, it would be the natural thing to accept materials that would afford the highest coefficient, as, for illustration, wrought iron on oak. Were the oak fireproof, the fact that the radiating surface is limited would make no difference at all, and the result would be extremely good. As it is, however, the oak begins to char at about 550 degrees centigrade, and, in automobile work, the radiating surface is so restricted that this temperature would be realized the first time the automobile so made were to be snubbed down a grade of any moment, and the brakes would soon be reduced to a point where they would cease to serve for the intended purpose.

Speed of Rubbing and Pressure per Unit of Area

In any event, when it is desired to get all there is in a given type of material, care must be exercised to so place the material, with regard to the speed of rubbing and the unit pressure, that the maximum result will be obtained. In this connection, metals follow one law and fiber-like fabrics obey quite another set of conditions. To substitute fabrics then, in place of metal to metal, is to court a different result, and the substitution may be the difference between success and failure.

Very little has been added to the store of real knowledge on this subject for many years; old theories have been verified to be sure, but what is now known has been known for a considerable period. Unfortunately, however, many designers pre-

(Continued on page 1194)

Questions That Arise—General in Scope

How to overcome a leaky combustion chamber——Eliminating rust from wheels——Soap has various virtues besides its cleansing properties——Acids in mineral lubricating oil——The lever system as used in automobile work——To prevent tools from rusting——A good lacquer for bright work on automobiles——How to locate cylinder cracks.

[133]—Would it not be possible to counteract the trouble of this sort by the simple expedient of firing gunpowder when the piston is well down on the stroke, and regulate the quantity of gunpowder so that the pressure will be maintained at the desired level?

There is scarcely any doubt of it.

[134]—Then why not use it; surely, self-starting is much in need?

Just so soon as self-stopping can be guaranteed, then self-starting, using gunpowder, will be an excellent idea; most individuals want to know that they are going to stop as well as to start. Gunpowder, gasoline, an electric ignition system, and a man of no brains, should make a combination that would demand the attention of law makers.

[135]—When a pipe in a combustion chamber of a motor fails to maintain tightness against compression, if grinding in cannot be resorted to, what is the surest way to overcome the trouble?

Cement, if it is made of litharge and glycerine to form a cement-like mass, if it is freshly applied (using pure glycerine), will serve the purpose. This cement is heat and acid-proof and possesses more than the ordinary virtue. It fails when the glycerine is diluted with water, as it frequently is, or if the litharge is adulterated, which is one of the regular occurrences.

[136]—When rims of wheels of the clincher or other types become rusty, what is the best way to eliminate the trouble?

Considering rust as a disease which is likely to spread, even if nearly all of the rust is removed before a new coat of japan is applied, it would seem as if the right principle is the one which would demand the use of iron rust in the mixture to be applied. Anti-rust coatings, then, if they are to be particularly efficacious, will abort the disease. Beeswax has this virtue; it combines with iron rust in such a way as to prevent the further formation of the rust. If the beeswax is applied hot, or if the rim is heated before the beeswax is rubbed over the surface, it will serve as an anti-rust coating, nor will the beeswax attack the fabric or the rubber compound of which tires are made. In the application of the beeswax it is not necessary to remove absolutely all the rust from the rim. All that is necessary is to scrape the rim so that it will present a smooth surface for the tire to contact with.

[137]—Is there any virtue in soap as a lubricant?

Any slippery substance is a lubricant; it may also have the property of etching the surfaces of the bearings. In the discussion of a question of this sort, then, it is necessary to consider the two points, (a) lubricating, and (b) etching properties

[138]—Is soap an etching ingredient?

If it has an acid reaction, yes.

[139]—Is it likely to have an acid reaction?

Yes.

[140]—Why?

Because it is composed of animal fats, saponified.

[141]—How is animal fat saponified?

A certain proportion of animal fat (vegetable oils may also be used) is diluted with water, and potash, or lye, is added, the whole is boiled to a certain consistency. The following are some proportions:

(A) Normal grade of soft soap.

Oil and tallow	45.0 parts
Potash	8.5 parts
Water	46.5 parts
Total	100.0 parts

[142]—What is soap?

It is a chemical compound; it is not oil, fat, potash, nor water. It is made from these.

[143]—What part does soap play in the etching process which is so undesirable for ball or roller bearings?

The fat may be acid in its reaction; it may produce acid by decomposition.

[144]—What is the composition of lubricants which utilize soap?

English railway axle grease:

	Summer.	Winter.
Tallow	504	420
Palm oil	280	280
Sperm oil	22	35
Caustic soda	122	126
Water	1,372	1,524

Proportions are all in pounds, and the quantity of caustic soda present, with water, is that which will saponify.

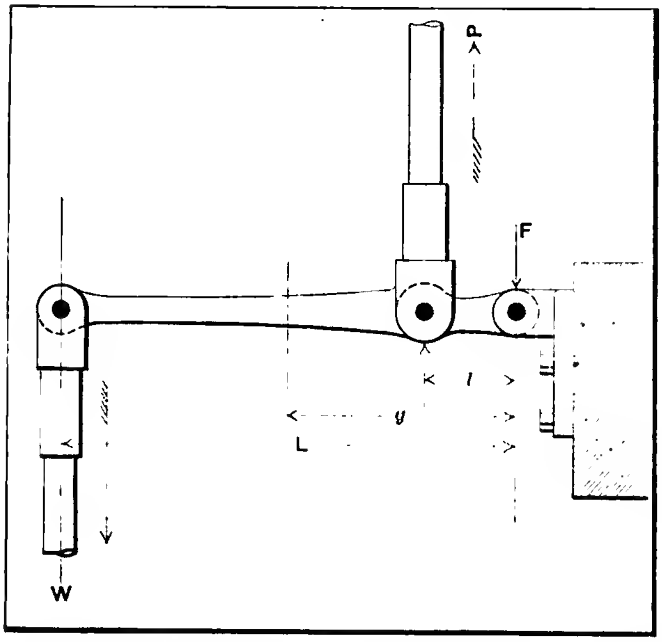

Diagram of lever system frequently used in automobile work

[145]—How is it possible to determine if soap is present in lubricating grease?

The soap is soluble in water.

[146]—How is it possible to tell if there is acid in the lubricant?

Litmus paper offers an excellent means for ascertaining an acid reaction in a solution. Tallow and most animal fats will decompose when exposed to light; if the grease, holding tallow or other acid-producing fats, is carelessly stored or much aged, it is likely to generate sufficient acid to etch the delicate surfaces of ball or roller-bearings.

[147]—Is there any chance of acid being present in mineral lubricating oil?

Yes; in the purifying process, acid may be used. One way to purify lubricating oil is to add a small percentage of oil of vitriol; agitate, and then wash the oil with water, agitating until it is freed of the oil of vitriol; it is well within the range of possibilities that some of the oil of vitril will remain in the cleaned oil when it is siphoned off. After siphoning the oil must be stood over quicklime. An acid test is necessary in order to determine whether or not all the acid has been washed out: if a trace remains, it is scarcely feasible to employ the oil in the process of lubricating ball or roller-bearings.

Computation Method for a System of Levers

[148]—The lever system as here illustrated, being frequently used in automobile work, is generally computed on a basis of no friction: what is the necessary change in the formula if it is desired to include some estimate of the friction elements?

Let

W = the weight or pressure applied in the direction of the arrow at the end of the lever,

L = distance in inches from the fulcrum F to the end of the lever at W,

w = weight of lever in pounds if it lifts vertically, or the equivalent in friction, if it slides horizontally,

g = distance between center of gravity of the lever and the fulcrum in inches,

l = distance in inches between fulcrum and center of pullrod P,

V = weight of pullrod P if it is suspended vertically, or the equivalent friction, if it slides horizontally,

P = pull in pounds exerted on the pullrod P,

When

$$W = \left\{ P - \left[V + \frac{(w \times g)}{l} \right] \right\} \times \frac{l}{L}$$

or,

$$L = \left\{ P - \left[V + \frac{(w \times g)}{l} \right] \right\} \times \frac{l}{W}$$

The center of gravity of the lever may be found by balancing it on a V-track; it may also be determined by calculation.

[149]—How can tools be prevented from rusting?

Melt 1 pound of fresh leaf lard; add 1-2 oz. of camphor; remove the scum that forms, and add graphite to give the desired color and consistency. When the anti-rust paint thus made is cool, apply it to the surfaces of the tools; after cleaning them thoroughly, and when the coat has stood for a period of 24 hours, use a soft linen cloth to polish. This treatment will save the tools for months under the most severe conditions of salt-sea air, and they will always have a presentable appearance.

[150]—To soften the glare of headlights, is there not some way of coating the glass front?

Prepare the glass by first washing it in hot water with plenty of soap; dry thoroughly; dip in a bath made by adding the white of eggs, two to the pint, and filter the egg solution before dipping. When the glass fronts are well coated with the egg solution, lay them by to drain and dry. With the glass ready for the dimming process, it remains to select yellow aniline dye, and after dissolving a small part of it in collodion, it will be ready to apply to the prepared surfaces of the glass. A thin coat is best; apply repeated coats to get the desired dimming effect. The glass will take on a frosted effect; the glare will be softened, and the coat will be waterproof and serve for a long time. The coat may be removed with alcohol.

[151]—What is a good lacquer for bright work, as lamps, rails, etc., on automobiles.

The lacquer prepared as here given will serve very well indeed, but it is necessary to prepare the surfaces to be lacquered if the results are to be satisfactory. For the surfaces, what is wanted is a high polish and absolute freedom from grease. The lacquer may be prepared thus:

Bleached shellac	60 grams
Manila copal, freshly powdered	60 grams
Gum mastic	60 grams
Absolute (grain) alcohol	1 kilogram
Coarsely powdered glass	small quantity
Allowed to stand for (frequently shaking)	14 days
Boracic acid	1 gram

Filter and use, the best plan being to apply repeated thin coats with a camel's hair brush.

Any desired color may be given to the lacquer by adding aniline dyes. A very little of the dye of the color selected will serve for the purpose. Red and blue will form clear solutions; green must be handled cautiously; it may have to be filtered; yellow is a good dye to handle. In applying lacquers it is desirable to go about it in the same way as shellac is applied—thin coats, deftly applied by means of a suitable brush, with very little rubbing; it will become tacky if it is fussed with very long.

Cylinder Casting Proves to Be Unsound

Editor THE AUTOMOBILE:

[2,310]—I have had my motor but a short time, and the other day when it failed to work, I had it taken down, dissembled, and the cylinders examined, and found that one of them was cracked, but on further examination, it was also discovered that a part of the bottom flange was fractured, and a close examination of the fracture showed a defect in the section of the metal which leads me to suspect that it was not a very good casting. What are the expectations with cylinder casings? SUBSCRIBER.

Minneapolis, Minn.

Fig. 2 shows how cylinder castings may be defective, due to design, and almost independent of the quality of the metal used. A is a round section of considerable diameter, and shows a soft core. B shows a hole in the core of the same section, which is about the size necessary to cut away the defective metal. C is a square section, showing how the defective metal bunches at the center and trails away toward the four corners. D shows a rectangular section, and how the metal verges into the defective after a fashion somewhat as shown in C. E presents an angular section, and shows the probable zones of defect. F presents a section without any sharp turns, but with even thicknesses of walls, but no defects. G presents another design which is generally defective, and H shows how defects may be eliminated. In cylinder designing, if large fillets are used where walls verge into each other, defects will abound, or if the flanging at the bottom is very thick, it is likely to be spongy. If the material is not good, or if the foundry work is indifferent, defects may be due to these causes.

Metallic Hose Used for Water Connections

Editor THE AUTOMOBILE:

[2,311]—I have a water system on my car which is bad because there are considerable lengths of rubber hose, and they leak even though they do not rot out. Most of the leaks are at the joints. Is there any way out of this trouble, besides putting in a proper coppersmith's job? J. A. W.

Wichita, Kan.

Fig. 3 shows flexible metallic hose connections on a motor and experience with this material has been very good, not only with the water, but with the exhaust and intake connections as well. The flexible metallic hose can be ordered with makeup connections, and if the measurements are properly taken, the autoist can attach the hose in place with very little trouble to himself. This method is more expensive than garden hose. There are various forms of flexible metallic hose, and one of the most acceptable types is made of copper tubing which is put through a mill and reduced to spiral corrugation form.

Best Way to Cool Valve Stems of a Motor

Editor THE AUTOMOBILE:

[2,312]—I am working on a new design of a motor with a view to turning out a commercial car which will class favorably with the best products along other lines, excepting that I propose to make everything as nearly automatic as possible, and get as far away from the trouble that the driver will have to attend to as I can. In my experience, I have found that valves are a source of quite some trouble, and I think they ought to be properly cooled, and that the valve should be in a separate housing, so that the seat can be examined outside of the motor, but I do not like the overhead type of valve construction, and want to know how to accomplish the same purpose without putting the valves in the head. READER.

Dubuque, Iowa.

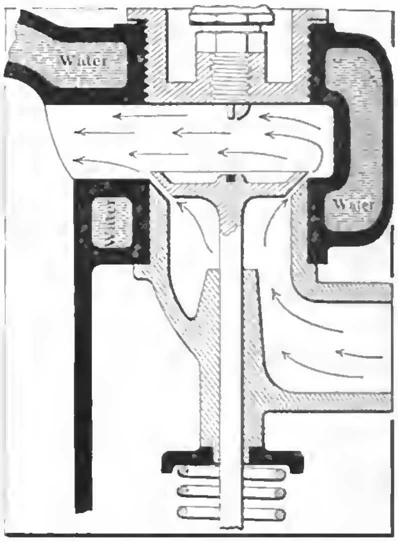

Fig. 1—Design of valve having the advantages of the valve in the head without the location which is objected to

Referring to Fig. 4 it will be observed that the valve and its housing are independent of the cylinder casting, but are inserted in the T-type of cylinder from the underside, but the water-cooling is quite as efficacious as would be true were the seat and its casting integral with the cylinder. The water-jacket extends all around, so that it cools the seat perfectly.

Thermo-Syphon System of Water Cooling

Editor THE AUTOMOBILE:

[2,313]—If a large water pump is necessary in some types of automobiles for circulating the cooling water, how is it possible to get good results without a pump? I understand that quite a number of automobiles are run on the thermo-syphon system, and that there is no pump employed in this case. M. C. K.

Richmond, Va.

The illustration, Fig. 4, shows a thermo-syphon system in which no pump is employed, and the water circulates in the direction as shown by the arrows. While it is common talk to the effect that this system works by natural circulation, the fact remains that steam is generated at the hottest zone over the combustion chamber, and this steam, coming off of the surface in a slug, rushes away through the course of least resistance, and acts very much as the plunger of the pump. It has the potential force of the energy stored in it, and is perfectly capable of doing mechanical work in substantially the same way that the plunger of a pump drives water before it, or creates a depression into which water runs. In addition to the mechanical effect of the slugs of steam driven off during each power stroke, there is the natural difference in temperature between the water over the hot zones and that in the rest of the cooling system, and to some extent this difference is responsible for the circulation; this alone, however, would act sluggishly.

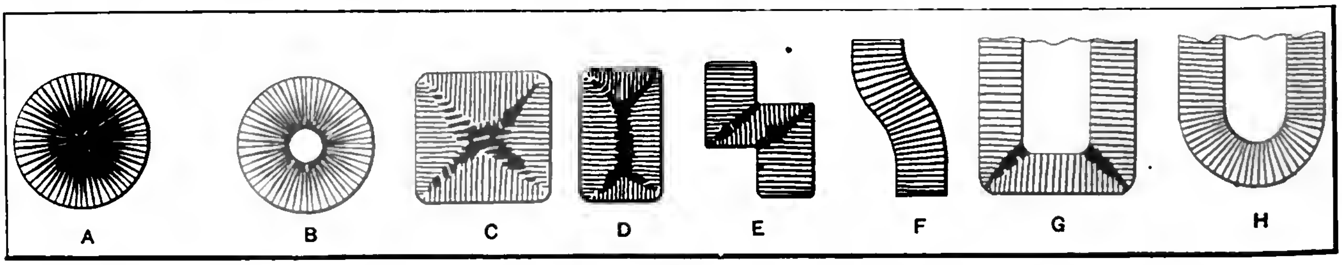

Fig. 2—Sections of cast gray iron showing how defects will be found at the cores of the thickest sections in each example

One or Two Small Details About Motors

Editor THE AUTOMOBILE:

[2,314]—Kindly answer the following questions through the columns of your paper:

1. What is the formula used in ascertaining the proper spring tension of an automatic inlet valve of a 4-cycle motor?
2. Would it be advisable to change the timing valve, when auxiliary exhaust ports are used on a 4-cycle motor?
3. What is the timing of a Franklin motor?
4. What is the best brake lining to use against a bronze shoe?

S. E. N.

Cedarhurst, N. J.

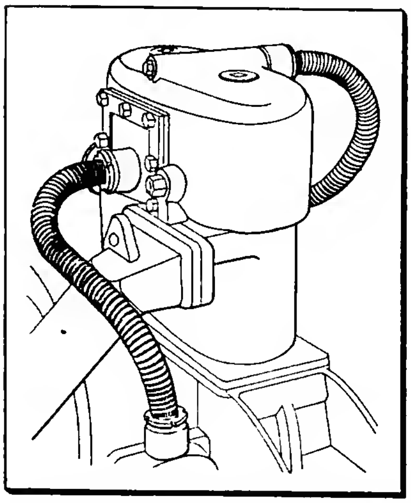

Fig. 3—Flexible metallic hose may be used in place of garden hose to good advantage—it costs more.

1. There is no formula which will be of any use in determining the tension of the spring of an automatic valve of a four-cycle motor; it depends upon the design of the motor, and a manograph should be used to ascertain the volumetric efficiency of the motor, also the greatest suction depression, and the spring should be strong enough to sustain against this depression.

2. Not if the timing is proper, independent of the auxiliary valve.

3. Direct an inquiry to the Franklin Company.

4. You have your choice between cork inserts and asbestos fabrics, either of which work independent of all possible temperature changes.

The Larger Tire Will Sustain More

Editor THE AUTOMOBILE:

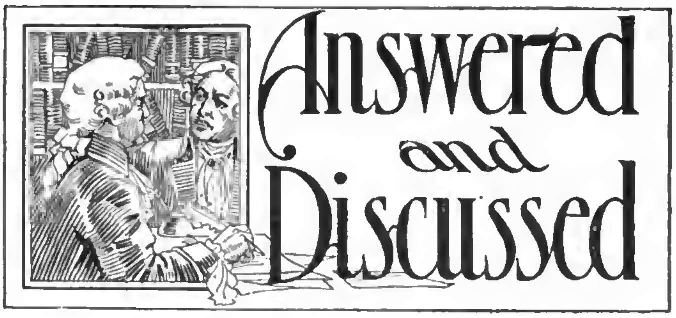
[2,315]—Permit me to ask you through your inquiry column the following question:

Why is a 4-inch tire on a 34-inch wheel base more desirable (if it is) than a 3 1-2 inch, leaving out the question of easier riding and less wear to machinery? On a 2500-pound car, 112-inch wheelbase, which size tire will cost the user less in the long run, and why?

Booneville, Miss. L. D. RINEHART.

The life of a tire, other things being equal, is proportional to the square of the section diameter. The square of 4 is 16 and the square of 3.5 is 12.25. The life of the 4-inch tire from this point of view will be as 16 is to 12.25 comparing it with a 3 1-2-inch tire.

The second question cannot be answered with the data afforded. To begin with, the best result will come from tires if they are properly inflated; in the second place, they will die of old age any way, and they will do useful work during their period of life if the opportunity is afforded. The service you can get out of a tire then, depends upon whether or not it is used continuously. Likewise, a dozen other considerations come into the accounting, but the smallest size tire that should be used on any automobile is that which will stay almost round when it is inflated up to the normal pressure, notwithstanding the weight which is put upon it. If the tire is not big enough it cannot be inflated to roundness at all.



Having Trouble Timing the Magneto

Editor THE AUTOMOBILE:

[2,316]—I am a subscriber to your valuable paper. Will you kindly answer the following questions through your columns:

I have a 4-cylinder car equipped with a Remy Magneto, and after starting the car, and then stopping it, by means of throwing the switch off, the engine will reverse and turn over several times, and there is knocking when this happens. Can you advise me what the trouble is?

Also can you advise me why my radiator should get to the boiling point and the water steam out of it, after driving 15 to 20 miles on high speed? I keep my spark advanced as much as I can, and use as little gasoline as possible. L. F. P.

Pittsburg, Pa.

The following is a communication from the Remy Electric Company in relation to this case:

Your communication of May 26th, outlining questions from some of your subscribers is received. In the first question, we would say in answer thereto, that the chances are that the magneto is not properly timed with the motor. We do not see how, if the switch is cut out, the engine can continue to run, even though backward. The cylinders must be dirty and full of carbon, which causes continued ignition. We would suggest that your subscriber first assures himself that the cylinders are clean, and that ignition is not caused by something other than the ignition apparatus. Next, be sure that the instrument is timed properly. The contact spring should leave the contact screw just as the piston passes over top center of the working stroke. An adjustment here of perhaps 10 degrees can be made by moving the contact screw in and out. The little line on the brass distributor should be exactly opposite one of the pegs, and the contact screw should leave the contact spring at the same time.

The fact that the engine pounds would indicate too early timing, which in itself would cause the engine to reverse, but we do not see how the engine can continue to run when the switch has been shut off, unless from some other cause than the ignition apparatus.

Your radiator, if it is large enough for its intended purpose gets hot and steams because you run the motor on a retarded spark, or as the Remy Company states, the magneto is not properly timed.

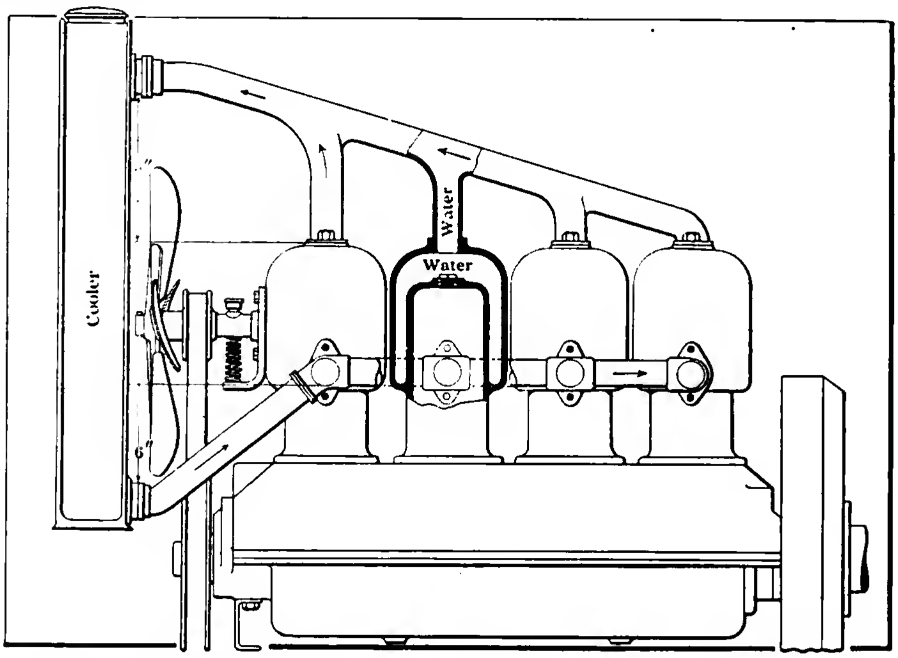


Fig. 4—Thermo-syphon system of cooling in which the steam generated acts as piston

Studies Involving Refinements of Gasoline Equipment

Points out that the filler cap for the gasoline tank should be made so that it will hold pressure. That gasoline will not flow through a fine wire mesh if it is wetted by water first. A water basin is shown to have advantages. Means for clearing the gasoline piping of scum and other obstructions, shown

WHEN a $5,000 automobile is prevented from running, due to the presence of a disorder which could be cured by five cents' worth of labor at the proper time, the man who pays for the automobile is afforded an opportunity to do a little hard thinking, but the maker who neglects to indulge in the cost of the additional labor required will find himself in a position where his many friends will generously disagree with him.

It is scarcely to be supposed that an automobile with a plugged-up gasoline pipe, if it reaches the purchaser in that condition, was ever tested by the maker to find out whether it was any good or not. In a case of this sort, the purchaser is bound to reach the conclusion that the maker is not very much interested in the quality of the automobile. Strange as it may seem, the maker of this generic type is frightfully particular that the quality of the money he exacts must deliver a musical ring. Is it not a reasonable demand of the purchaser that the maker be a little particular about the finishing and tuning up of the automobile? True, it runs into dollars to find all the little faults and correct them.

Referring to the type of gasoline tanks which are held under pressure, Fig. 1 presents a relatively large diameter filler, with a leather packing ring which is spread over a considerable area, and which is held in place by the large diameter of the washer, and the fact that it inserts as shown at I1 and I2. The filler cap has a coarse thread, and a lead at the point marked L1, so that when it is placed in the position to be screwed on it will sleeve over for the distance of at least one thread, thus providing a position finder and avoiding the difficulty which is usually experienced in the act of threading on a cap.

This filler cap is of such large diameter that it will almost screw down to pressure tightness without having to use a

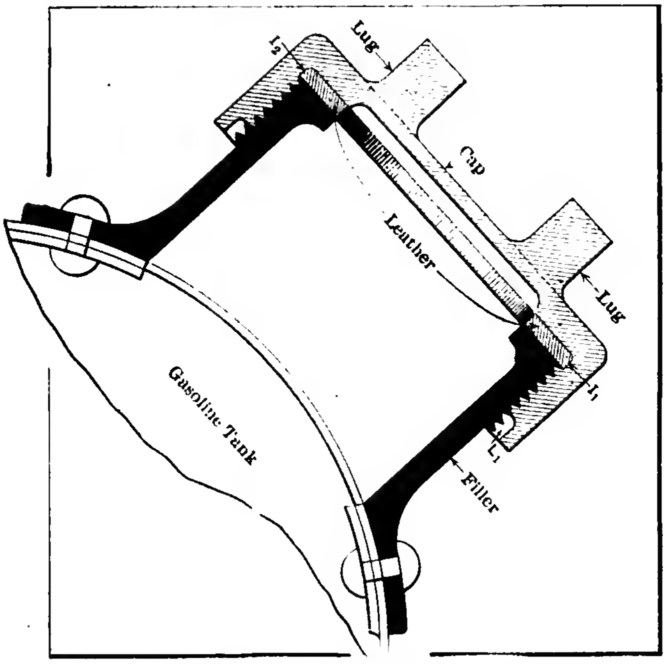

Fig. 1—Large-diameter filler, with leather packing ring

spanner wrench or any other device. Should the leather become defective or crusty, thus making it necessary to apply extra pressure in order to realize gas tightness, the lugs as shown project upward for a distance of 5-8 of an inch, so that a tire tool or any other handy length of material may be utilized to screw up the cap until it becomes tight. The leather packing does not have to be of any very special grade of material; calfskin is all right, cowhide will do; a thickness of 1-8 of an inch will give it the desired stability.

The filler cap screws down over the filler casting for a considerable distance, and the casting should be long enough to bring the filler orifice out in the clear, so that a funnel may be inserted in the orifice without having the diameter of the funnel scrape against the body finish. There is no reason why the filler casting should not neck out for any distance. In some types of automobiles this casting is even 24 inches long. Where the casting flanges to the copper of the tank, it should have a considerable bearing, and it should also be peened to the shape which will conform with the curvature of the shell of the tank. A reinforcement piece might well be placed around the orifice of the shell of the tank, so that the riveting for the filler casting will be more secure, but riveting alone should not be relied upon to make a tight joint. All the surfaces should be tinned over before the parts are assembled, and the joints should be sweated in order to complete the undertaking on a basis which will insure tightness under pressure.

Filters Are No Protection Against Water

The majority of men who run automobiles are imbued with the idea that a chamois-skin filter will prevent water from entering the gasoline tank, but they think they know that it will let gasoline go by. The open door from the chamois-skin point of view depends upon whether the chamois skin is first wetted with water or gasoline. If water is first applied, then water will go through, but if gasoline is first applied, then gasoline will go through. To further indicate the cantankerousness of a piece of chamois skin, it is only necessary to say that if it is wetted on one part by water, and over the balance of the surface by gasoline, a stream of water will flow through the part which is wetted by water, and a stream of gasoline will flow through the part which is wetted by gasoline.

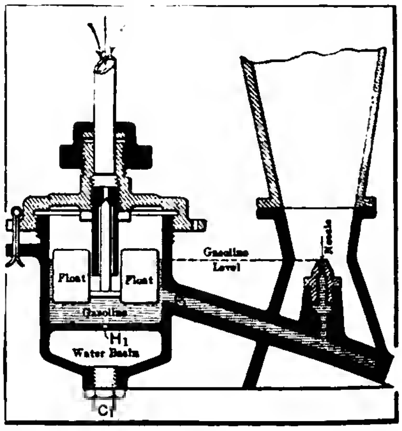

Fig. 2—Section of float bowl, with separate water basin.

What is true of chamois skin is equally true of a fine mesh sieve; contrary to the usual expectation, a sieve wetted with gasoline is just as good a protection against the flow of water as the protection afforded by a chamois skin. The very fact that a sieve first wetted with gasoline bars the flow of water, constitutes the reason why a sieve used in the bottom of the float bowl of a carbureter will prevent water from flowing out through the drain cock, even though it will let gasoline flow through up to the limit of its mesh capacity. The types of carbureters which are so made that sieves are placed to prevent the water from flowing out soon become water-logged, and the poor autoist who does not know enough to throw the sieve away is benumbed with the extent of the trouble which comes from the accumulating water, and if he goes to a repair shop which has a director who believes in the efficiency of a sieve, as a means for separating the water from the gasoline, he will come away without learning anything about his real trouble, and he may labor under the further disadvantage of believing that the trouble is elsewhere, which will prevent him from pursuing the right course for the purpose of eliminating the real trouble. Fig. 2 shows a section of a float bowl in a carbureter with a separate water basin at the bottom, and a hole, H1, in the separating wall which should be big enough to let a drop of water through. The gasoline passageway, P1, from the float bowl to the nozzle should have its orifice at the float bowl far enough above the bottom of the float chamber to prevent the drops of water from floating into the passageway impelled by the current of gasoline, which is set up by displacement in proportion as gasoline is sucked out of the nozzle. The drops of water which find their way into the float bowl under the conditions as shown will fall down into the water basin, where they will remain until the basin is filled with water, unless the autoist opens the drain cock C1 at sufficiently frequent intervals to drain the water accumulations out. There are many types of carbureters which belong to the float-feed family, and in point of general principle they are all very much alike. They all regulate the flow of gasoline, for instance, through the force which is represented by the buoyancy of the float.

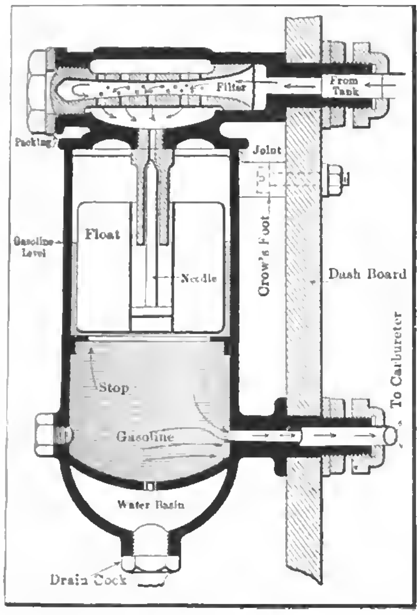

Fig. 3—Auxiliary dashboard tank, with filter

The needle valve is forced up against its seat by this manifestation of buoyancy when the bowl is filled up to the level which is on a hydraulic grade with the top of the nozzle in the depression chamber. The float may be made of copper, which should be light in weight, and relatively small, but if it is not properly made it may spring a leak, in which event gasoline will run into the float, and its buoyancy will be destroyed. Under such circumstances the float will not lift as the gasoline runs in and the carbureter will flood because the needle will not be pressed against its seat at the proper time, and the level of the gasoline in the float bowl will then be above the top of the nozzle in the depression chamber.

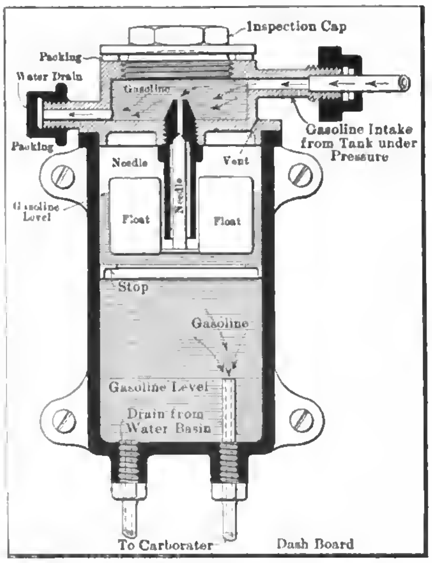

Fig. 4—A promising form of filterless dashboard tank

In order to repair this difficulty it will be necessary to remove the float from the chamber, enlarge the puncture so that it will be big enough to let the gasoline out, apply a little heat to drive off the vapor, and then solder up the hole, but in the act of soldering care must be exercised to permit air to enter to fill the space; otherwise a vacuum will obtain within the float, in which event the thin walls will fall in because the pressure on the exterior surface, which is 14.7 pounds per square inch, will exceed the pressure on the interior surface by the difference between the pressure of the atmosphere and the pressure of the vacuum within.

In some cases, floats lose a part of their buoyancy, as when the material is porous, and the result is that they sink to a lower level, so that the gasoline in the nozzle falls below the surface, and the mixture resulting is in a "starved" state. There are two ways of overcoming a difficulty such as this, one of which is to substitute a good float for the loggy one, and the other way lies in having a means of adjustment which will either permit of raising the height of the needle stem with respect to the float, or lowering the position of the seat for the needle with respect to the same, as shown in Fig. 2. There are divers mechanical ways of accomplishing this function, but it must be said that the cure is oftentimes worse than the disease, due to the fact that the adjustments when made by the means provided, will not stay made. Before administering his medicine it will pay the "doctor" to first thoroughly diagnose the case.

(*Continued on page* 1196.)

Some Ill-Advised Methods to Employ in Driving

Showing how the careless driver can materially decrease the life of his tires by attempting short turns with a long-wheel-base car. Inexpert work with the slide lever is very wearing on the gears, as is clumsy cranking on the anatomy of the operator.

TURNING around in a relatively narrow street, if the wheel base of the automobile is long, is likely to result in the situation which is shown in Fig. 1, another view of which is given in Fig. 2. The tire of the outer front wheel is brought into abrupt contact with the edge of the curb, and even if the fibre does withstand the shock for a time, it is more likely than not to be so weakened that the life of the tire will be much shortened. It is quite impossible to expect that the average automobile is capable of being turned around in a narrow street. Attempts have been made to render this possible; taxicabs, for illustration, are so designed that in view of a relatively short wheel base they may be turned around in a circle of approximately 35 feet in diameter. This means that the wheel base must be substantially 100 inches, and the locked position of the canted wheels must be about 36 degrees.

Obviously, to realize the ability to turn the car around in a narrow street, it is necessary to sacrifice some other important qualities, as a long wheel base; but the owner of a long-wheel-base automobile, who elects to take advantage of the qualities residing therein, offers wide opportunity for a high cost of tire maintenance if he fails to operate the long-wheel-base car in accordance with its characteristics. In a word, a long-wheel-base automobile in the hands of a short-wheel-base driver evolves the situations as presented in Figs. 1 and 2.

The relative advantages of the various types of transmission gears, as selective, progressive, three-speed, four-speed, etc., are common subjects for discussion, but nearly all the edifying talks on the subject fail to take into account the results which come from lack of deftness, or if the driver is timid. Fig. 3 shows how the clumsy learner fumbles the slide lever in the process of shifting gears; he fails to take into account the fact that the

Fig. 1—Outer wheel of the automobile strikes the curb in the process of turning the car around, injuring the fabric beyond repair

Fig. 2—Another view of the same automobile taken to show how the sharp edge of the curb eats its way into the tread of the tire

two relating members must be traveling at substantially the same speed before there is any use in trying to engage them; he might just as well understand that if two gears are to be meshed with each other, they must travel at precisely the same speed before the operation can be performed. There is really very little to learn about sliding gears, excepting to remember that the speeds must be identical, and then to be able to realize when this condition is present, and to understand that promptness is the one remaining virtue. When the meshing gears are operating at substantially the same speed, a deft movement of the lever will permit of engagement without even a click, but the clumsy clashing of gears results in the chipping of the teeth, and a character of depreciation which cannot be repaired.

The learner who is afraid of a back kick is the one who is most likely to get it; his very timidity results in his forgetting that he failed to retard the spark before cranking the motor. It is understood, of course, that the spark should be retarded so that ignition will take place after the piston comes up on the compression stroke, dwells at the end of the stroke for a time, and then recedes in the act of making the power stroke. If the spark is retarded five degrees, the piston will be across the dwell point, and will be sufficiently on its return stroke, so that if the mixture is ignited the force will be effective, and positively in the desired direction. If the autoist disregards the retarding of the spark, and then laboriously pulls the crank, using both hands, as shown in Fig. 4, he is making every point in favor of a resounding back kick, which should, according to the law of probability, make him eligible for a trip to a near-by hospital, and he will get off easy if he has nothing worse to complain of than a broken arm.

The danger attending a back kick is much accentuated in the types of motors which have a high compression. The rate of flame travel increases with compression, and unless enough energy is stored in the flywheel in the act of cranking to overcome expansive forces which retard the piston in its upward travel, this character of difficulty is especially likely to creep in as the product of high compression, and a lazy method of cranking. The right way to crank a motor is to positively retard the spark, and to crank smartly, so that enough energy will be stored in the flywheel during the earlier proportion of the compression stroke that the final effort will be with relative ease, due to the fact that the energy stored in the flywheel will be given up.

Fig. 3—A fumbling learner who does not know that gears to be meshed must be brought to the same speed and shifting deftly done

Fig. 4—Hugging the starting crank, waiting for a back kick, with the prospects of not having to wait very long

High Potential Test on Porcelain Spark Plugs

Tests were made in order to ascertain the dielectric strength of the porcelain used under the conditions fixed in spark plug. The conditions were: (a) with spark gap insulated; (b) without insulation between spark gap terminals.

IGNITION work is now regarded as of such great importance that autoists are justified in giving its details the most searching scrutiny. It is self-evident that the motor will be valueless if the ignition system fails to work, and it stands to reason that the part which is subjected to the highest strain should be of the greatest strength. It has taken a long time even for designers to reach the conclusion that the dielectric strain in the porcelain insulation of the spark plug is in many respects even more severe than the result due to combined torsion and bending in the crankshaft of the motor. A blow is struck when a high potential wave is impressed on the porcelain of the spark plug insulation, just as effectively as would be true of such a blow were it the direct result of contact with a falling weight or were it hit with a hammer.

When a magneto is used as the source of electrical energy, it is so contrived that it builds up its voltage, increasing until the resistance of the spark gap in the spark plug is broken down, and if this is true, the higher the resistance of the spark gap, the higher will be the voltage of the magneto. High resistance in the spark gap is brought about by increasing the length of the same, but if the porcelain fails in point of dielectric strength the length of the spark gap may be regarded as in excess of that allowable.

Considering these circumstances, it is safe to reach the con-:lusion that the ability of the magneto, all other things con-idered, is absolutely limited by the performance of the spark lug. This is not to say that the magneto is to be condemned f a spark plug proves to be unruly, but it does indicate that here can be no higher voltage delivered by the magneto than hat which will break down the gap in the spark plug, or if e porcelain is weaker than that indicated by the voltage which erces the gap, then the porcelain holds in its make-up the niting factor.

A considerable number of tests, which were made for the rpose of determining the performance of porcelain as used in ark plugs in ignition work, would seem to indicate that the electric strength of porcelain is sufficiently high for every ictical purpose. The tests invariably show that when the celain fails to sustain, the trouble is due to arcing over her than to the breaking down of the section of the same. is arcing over difficulty depends upon the character of the face, its condition, and the distance between the electrodes.

Method of Conducting the Spark Plug Tests

every case, the high potential tests on the spark plugs e made by applying an alternating voltage between the term-stem and the shell; first with insulating material between terminal of the spark gap proper, and second, without the lating material in the spark gap. The first test is made etermine the breakdown voltage of the porcelain insulator. second test shows the breakdown voltage of the spark gap. e voltages are applied at a low value, raised gradually, and effect noted. The approximate time which elapses between irst application of the voltage and the instant of arcing is ally about ten seconds.

e transformers used have a capacity (maximum) of three olt-amperes, with a normal ratio of 6,000 to 100, which eans of suitable mechanisms may be changed to 4,000 , in which event the output is normal at 3,000 kilovolt-es. The voltage is measured across the low tension cir-connection with the ratio of transformation. The source rrent is a sixty-cycle circuit, the voltage wave-form is ally a sine curve, and the voltages given in the statement s are what is known as "effective"; in other words, they are square root of mean square values.

Some Practical Results Obtained

T'st No.	V'l't'ge Applied	Remarks
XX	17,400	Arced over upper and lower surfaces
X	5,220	Arced from terminals to shell
AX	2,700	Arced from terminal to shell

The above tests were taken at random from spark plugs of different designs, and they show the wide variation which is due, not so much to the character of the material used in the porcelain, or the method of its manufacture, as to the distance between the electrodes as it influences arcing over the surface.

None of the preceding tests show the voltage which is possible across the spark gap, when the porcelain is so placed in its housing that arcing across its surface between terminals is aborted. When the porcelain is properly protected so that it is in a position to do the work for which it is intended, then the air gap voltage ranges all the way from 16,000, which proved to be the puncture point for the particular porcelain which was tested, down to 1,640 volts, which was limited by the poor way in which the insulation was used, so that instead of building up a higher voltage, arcing across from metal to metal over the surface of the porcelain took place.

In every test made so far at the Electrical Testing Laboratories at Eightieth street and East End avenue, New York City, according to a statement which was made to the Editor of THE AUTOMOBILE, care was exercised to have the porcelain surfaces perfectly clean and dry, and to note the relative humidity during test, room temperature prevailing, and such other data as would be likely to have bearing upon the subject. It seems, from the experience thus far afforded, that the average spark plug fails, not because the porcelain is inferior, but for the reason that it is not advantageously placed in the metal portions of the spark plug.

It is a source of some regret that the investigations thus far conducted do not include tests which will show the effect of service on the porcelain as used in spark plugs. There are no test data available for spark plugs which are discolored in service, and the question naturally arises as to the effect of discoloration, also of temperature and time. As one of the great questions which will have to be disposed of before the automobile may be regarded as well on the road to standardization, this spark plug situation will have to be investigated, and when a sufficient volume of data is available, it will be a nice undertaking for some board of competent jurisdiction to sort out the things that are for, and the factors that are against, the best obtainable result, and reduce the desirable portions to an intelligible standard.

If it is possible to realize 16,000 volts in the air gap without piercing the insulation in some one case, then it is accepting less than the obtainable result to put up with anything below this figure. If a spark of great energy is necessary under the conditions which obtain with automobile motors, it follows that in addition to a magneto which is capable of furnishing the electrical energy, a system of spark plugs must be employed which will stand up under the work and excite the magneto up to its maximum safe limit.

High Tension Cable Insulation Tests

It has been found that the heat which abounds around motors is high enough to affect the insulation resistance of the high tension cable unless it is so made as to take this issue into account. Good cable, as selected for ignition work, tests up to about 27,000 volts before breakdown—high enough to serve very well, especially if the spark plug becomes the limiting factor.

COLUMBUS, O., June 27.—Although the Columbus Automobile Club is not yet three years old it has achieved a notable reputation for push, efficiency and civic pride. It exerts a great influence in motor circles in the Middle West and to its efforts is due, in appreciable measure, the good feeling toward automobile owners which is shown in Columbus and vicinity by the general public.

The club was organized early in 1908 by a small band of enthusiasts who saw the need for a closer organization of motorists in this section. The club began to grow from the moment of its birth until to-day it holds an enviable position among Ohio automobile clubs.

The first officers of the club were: Max Morehouse, president; Perin B. Monypeny, first vice-president; Dennis Kelly, second vice-president; Herman Hoster, secretary, and E. M. Schoenborn, treasurer. The first form of organization was that of the usual association where the officers generally do all the work and assume all the responsibility.

After prospering for about a year with that style of organization the constitution and by-laws were radically changed and the present style of organization was brought into being. The club is now organized after the prevailing plan of automobile clubs, with a board of governors, having full authority to look after its welfare.

The present officers of the club are: Charles E. Firestone, president; Norman O. Aeby, first vice-president; Charles C. James, second vice-president; Arthur M. Crumrine, secretary, and Herbert A. Mason, treasurer. These officers, with the exception of the secretary and augmented by Perin B. Monypeny, Nelson J. Ruggles, William M. Frisbie, N. J. Hanly and the Rev. J. H. Dodshon, constitute the board of governors.

One of the first steps taken by the club was to establish headquarters in the Northern Hotel building, near the corner of High and Goodale streets. The club rooms are located on the ground floor and have been fitted up in excellent taste by the house committee. As shown in the accompanying pictures, the rooms have spacious lounging and smoking apartments, a private meeting room, a secretary's office, cut off from the main room by a railing, and a reading room.

Tasty tapestries and draperies have been used to beautify the retreat and lounging room, which is fitted up with various colored electric lights. Servants are in attendance at all hours to look after the needs of the club members and their guests.

With the change of the constitution and by-laws Secretary Crumrine has originated a plan of holding a social session every Monday evening. The members readily accepted the idea and every Monday night sees a large number in attendance. A "Dutch lunch" is served and varied attractions are provided for the amusement and instruction of the members. Upon those occasions music is one of the features and singing and dancing often follow. This plan has done much to foster enthusiasm in the club and has proved quite a help toward the enrollment of dozens of motorists in the organization.

But it is not in social matters that the club has taken a foremost position. Through its legislative committee it has kept a close watch on laws and prospective laws and during the session of the Ohio General Assembly of 1910, which has just adjourned, it was through its efforts that no change was made in the present Ohio automobile law. The club co-operates with the automobile clubs of Cincinnati, Cleveland, Dayton and other Ohio cities in looking after legislative matters. The club has united with the Ohio State Automobile Association, which has grown into a strong and efficient organization, to further the interests of the 35,000 automobile owners in the Buckeye State.

The club has erected danger and road signs over all the leading highways in the central part of the State. It has co-operated with clubs of Zanesville, Dayton, Springfield, Chillicothe, Marion and other cities, to place legible road signs all over the State of Ohio, thus aiding the tourist who may be traveling strange highways.

The club has gone on record time and again against the reckless driver and the scorcher. Always ready to uphold the law, it has become popular in a community where the feeling several years ago was intense against the autoist. The club frowns upon the man who jeopardizes the status of the 2,500 autoists in Franklin county, by disregarding the speed laws and the traffic regulations of the city. Yet, on the other hand, the club is always ready to defend its members who may be accused unjustly of reckless driving.

The Columbus Motor Show, held during Christmas week, 1909, under the auspices of the Columbus Automobile Club, was an unqualified success. While the attendance was not as large as was expected, still, judging from the number of cars exhibited and the enthusiasm displayed, no show was more of a success. The club proposes to make it an annual event and committees will soon be named to make the preliminary arrangements.

The annual Orphans' Day has become a feature of the activities of the club. In 1909 about 1,800 deserving children were given an outing at the grounds of the Columbus Country Club and not a mishap marred the occasion. The 1910 Orphans' Day at Big Darby Park, 13 miles west of the city, June 22, was a marked success. About 300 motor cars were used to haul at least 2,000 children to and from the park. A luncheon was served and numerous amusements provided.

When the club turned its efforts to securing better roads for Franklin County and Central Ohio, the roads of this section were known throughout the State as the worst in Ohio. That condition has been improved materially in the short time the club has been in existence and the roads of Central Ohio favorably compare with those of other parts of the State. There is still considerable to be done in that direction and the club has pledged itself not to cease working until the roads are in a perfect condition.

The recovery of stolen automobiles is a point that should not be overlooked in giving a résumé of the activities of the club. Co-operating with the police department and the State automobile department, the Columbus Automobile Club has been instrumental in recovering quite a number of stolen cars. The culprits have also been punished through the efforts of the club.

A stenographer, to take letters from the members, has been one of the things that has made the club popular among busy men. Other conveniences, such as telephone service, messenger service, etc., are provided.

From the small beginning the organization has grown to a membership of about 660. There are several classes of membership, including active, honorary and associate. A large proportion of those enrolled belong to the active list.

One of the best services the club has done for Ohio motorists was the fight against the principle of municipalities enforcing licensing ordinances. An ordinance of that character was on the books of Columbus and the club filed an injunction suit to prevent the city auditor from collecting the city tax fees. After fighting through the lower courts the club was rewarded with victory in the Ohio Supreme Court, which held that no municipality had authority to enforce an ordinance providing for licensing or registering motor vehicles. This decision relieved the thousands of auto owners in Ohio from a double fee for registration of their cars in addition to the usual practice of assessing them as personal property.

In fact, the club aims to carry out the objects of the organization, which are stated in the constitution to be as follows: "The promotion of a social organization or club composed in whole or in part of persons owning automobiles for personal or private use. To afford a means of recording the experiences of members and of others using automobiles. To promote original investigation in the development of motor carriages. To co-operate in securing rational legislation and the formation of proper rules and regulations governing the use of automobiles in city and country, and to protect the interests of owners and users of automobiles against unjust and unreasonable legislation, and to maintain the lawful rights and privileges of owners and users of all forms of self-propelled vehicles, whenever and wherever such rights and privileges are menaced. The encouragement and development in this country of the automobile. To promote and encourage in all ways the construction and maintenance of good roads and the improvement of the existing highways, and generally to maintain a social club devoted to the automobile and its vogue. To encourage the erection of road and distance signs at cross-roads and dangerous places. To promote the sport of automobiling whenever and wherever it can."

The chairmen of the various standing committees are: Membership, Herman Hoster; Legislative, William M. Frisbie: Show and Contest, Perin B. Monypeny; Good Roads and Road Signs, Herbert A. Mason; Auditing, O. H. Perry; House and Entertainment, Nelson J. Ruggles, and Publicity, Charles C. Janes.

The Automobile is a consolidation of The Automobile (monthly) and the Motor Review (weekly), May, 1902, Dealer and Repairman (monthly), October, 1903, and the Automobile Magazine (monthly), July, 1907

AMONG the great problems which make up the economic situation, the position of the farmer is the first to be taken into account, and anything that will keep the farmer's son from coming into town, thus adding to an already congested situation, will be a step in the right direction. But if the farmer's son is wanted in the field, it is not too much to surmise that a set of conditions must be induced and maintained, the character of which will be in keeping with the grown-up ideas which now pass current among rural women folks. That the automobile is the best bait that was ever offered for the purpose of bringing harmony into these relations is now an established fact.

* * *

TWENTY-FIVE gallons of gasoline, even assuming that it is enough of a storehouse of energy to furnish the force which will drive an automobile for 250 miles, will run out sooner or later, and the bottom of the tank frequently "lights up" with the unfortunate autoist three miles from the nearest place of replenishing. The trouble is that the gasoline is bound to run out no matter how big the tank, and the last drops depart as silently as the first gurgle out of the tank. There is one remedy which is applied from time to time; it takes on the form of an auxiliary gasoline tank, which is placed on the dash or elsewhere. The trouble with the remedy lies in the fact that the poor autoist does not know when the main tank is empty, nor is he advised when the auxiliary tank is being drawn upon, so that the only difference between the original trouble and that which comes with the auxiliary tank is in a gallon of gasoline. If some means could be provided which would tell the autoist when the main tank is empty, he would have sense enough to shape his course for a new supply within a distance which could be covered by the force of the fuel within the auxiliary tank.

* * *

LUBRICATION is being examined with a critical eye. One phase of it is occupying the attention of the readers of THE AUTOMOBILE at the present time—force lubrication being the subject. It is a great misfortune, the fact that every author in describing a system lays so much stress upon it that all other systems are cast in a shadow. The life of an automobile is absolutely dependent upon the efficacy of the lubricating system. It is also a fair statement that a bearing which will not thrive under ordinary conditions will survive under conditions of force lubrication.

* * *

ANY system of lubrication which depends upon force, otherwise than that due to gravity, works when the mechanism is in working order.

* * *

THE force of gravity is working all the time.

* * *

ELIMINATING the gravitational consideration, the mechanism which is placed to serve as the conveyor for lubricant will be just as detrimental an obstruction as a wad of waste when the mechanism gets out of dorder.

* * *

DOUBLE ignition systems are used on automobiles at considerable expense in order that the autoist will still have something to rely upon when one system becomes deranged. Is it not more to the point to have a double lubricating system?

* * *

WHEN the ignition system becomes deranged, the motor simply shuts down; but when the lubricant fails, the bearings of the motor are destroyed.

* * *

FORCE feed lubrication, because it offers certain advantages, should have the attention of designers; but it should not be so designed that it will thwart the force of gravity and deprive the autoist of a natural and reliable auxiliary system of lubrication.

* * *

IN the selection of material for use in the construction of automobiles, the laboratory method of arriving at conclusions is relied upon to produce dependable results. It is shown in an article on testing steel how some of the results obtained carry with them a considerable measure of misfortune in that they cast doubt upon good materials, and fail to sufficiently lay bare the defects in the other kind. It would be good practice to rely upon the steel fabricator unchecked, in the face of a system of testing which falsifies.

TELLING the embryo autoist how to avoid mistakes is a very pleasant pastime; he probably enjoys the situation quite as much as anyone. But how are we to tell the experienced autoist how to judge distance? Napoleon never measured the ability of a cannoneer on the meter-stick of bravery; it mattered very little as to the courage of the gunner; he would not be allowed to run away even if he wanted to. The real gauge for ability was in the eye of the man; if he could say how far it was from the mouth of the cannon to the mark to be hit he was a first-class gunner. It is this peculiar ability which is needed in the autoist who persists in forging ahead, even when a situation is complicated so that he has to dodge a brewery wagon on the right hand, and take a chance on running over a fruit vendor on the left.

* * *

STANDARDIZATION is a condition which is said to reside in every automobile made, but the article on spark plugs this week is at wide variance with a dictionary interpretation of the word—there must be some mistake.

* * *

IN the foreign exchange there is quite a concise article bearing upon the question of the analysis of lubricating oil. It shows how to detect the presence of resinous oil in the mass, and besides offering this aid, it tells a negative story—resinous products, which are anything but good lubricants, must have been present in the oils which came to the notice of the author; otherwise he would not busy himself telling about how to locate them.

* * *

FORE-DOOR types of automobile bodies are much in vogue, and they offer many attractions. Should they become over-prevalent, other types of bodies will pass out of style. The series of articles, which are now being run in the pages of THE AUTOMOBILE, tell how old bodies may be recast, at small cost. The plan which is being consummated is one which makes it possible to use the old body in the new work, so that the whole cost is confined to that of the addition of the fore-doors, together with a new dash.

* * *

AUTOMOBILE clubs, of which there are upwards of one hundred in first-class working order scattered through the country, are doing such excellent work that it is to be hoped that they will grow and prosper. We sometimes wonder if a lone autoist with a proper grouch, and no way to dispose of it to advantage, remembers that he becomes a thousand strong in the simple process of registering himself as a private in the ranks of a live club. Admission to a club does not carry with it the right to dominate the whole situation. A good club citizen ought to be satisfied by having himself spread out a thousand-fold.

* * *

VALVES, when they are tight, and properly timed, perform their functions precisely; but the autoist who may have discovered that a very minute leak around the spark plug, where it is screwed into the cylinder, will prevent a motor from performing, should have no difficulty in realizing what it means if the valves are in a leaky condition. When a man buys an automobile, he should select the kind which is so made that he will be able to grind in the valves; but when he fails to take advantage of facilities afforded, he will have himself to blame if he has to struggle up every "two-penny" hill on low gear.

* * *

THERE is something of a furor which dims the valorous performances of many of the automobiles which are entered at the various meets, due to the "stock-car" requirements as they are set forth in the rules which were promulgated by the "Contest Board." Of course, those who enter protests are fully alive to one of the requirements in law—"The seeker for justice must come into Court with clean hands." Blackstone is just as good for the plaintiff in front of the "Contest Board" as it is for the plaintiff in a Court of Equity. In the meantime, it would not be too much to expect were the "Contest Board" to furnish finger bowls for such of the plaintiffs as may have occasion to use them.

* * *

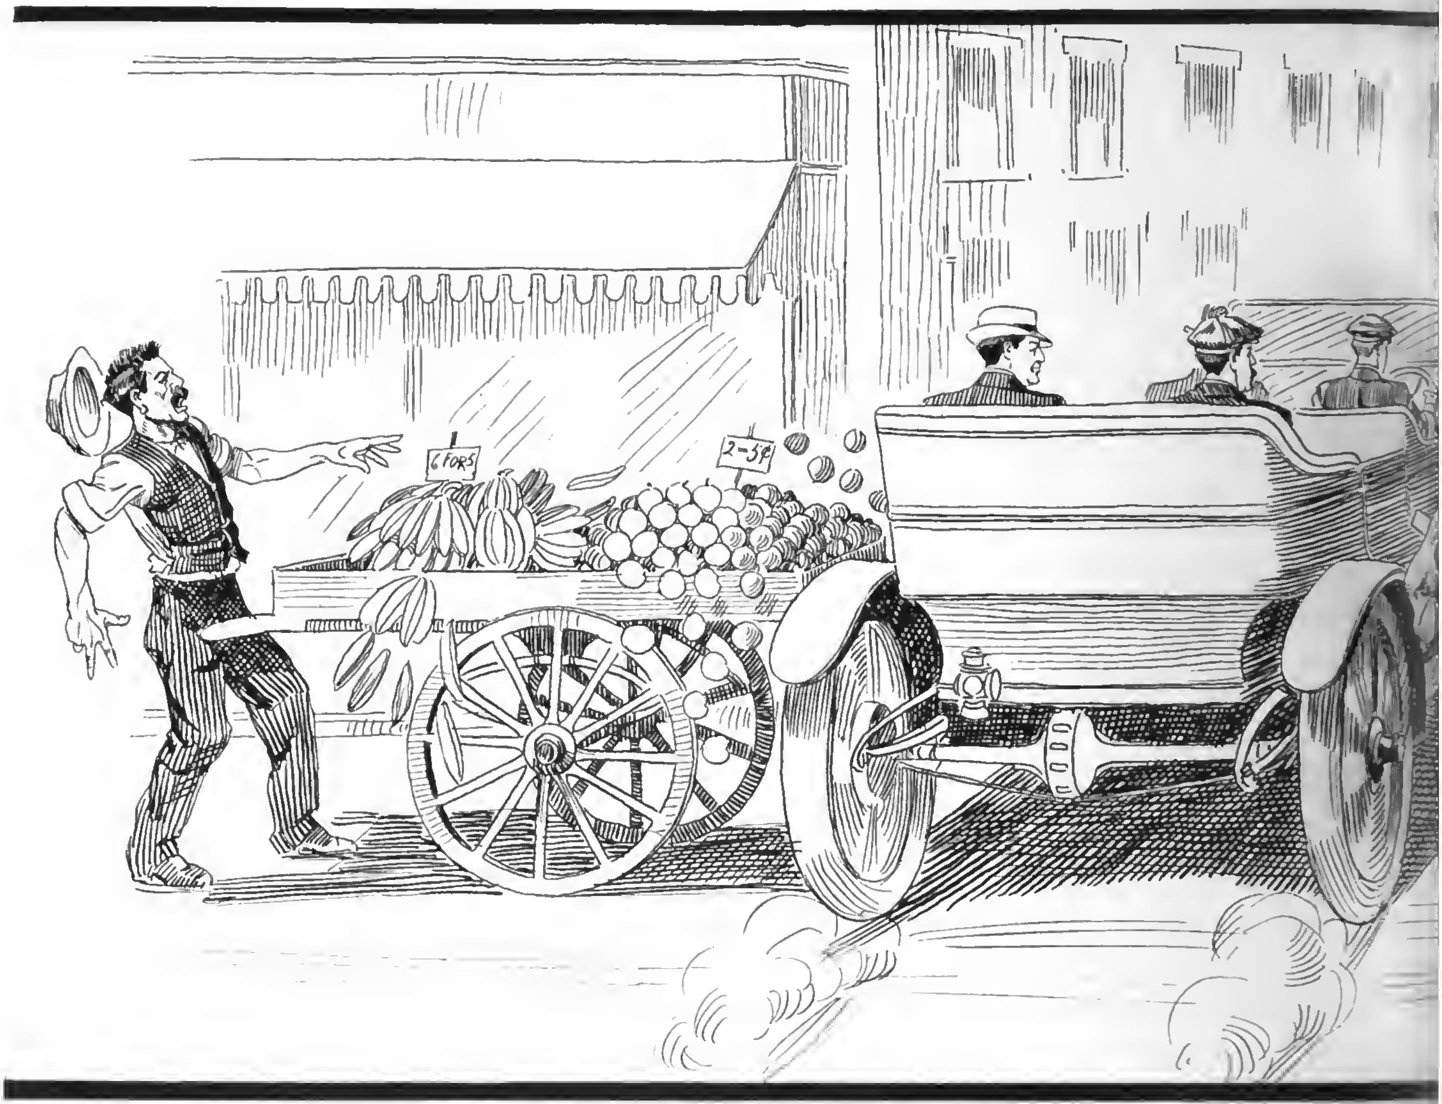
WHISPERINGS coming from the Glidden Tour direction are quite a little out of tune. That the situation is not entirely satisfactory to the makers of automobiles which are entered is the gist of the plaint. It would have been of incalculable advantage to the makers who are supporting this effort had they taken the matter in hand originally, rather than to leave the decision as to the itinerary of the tour to the third party. It is all very well to talk about good roads, and the invasion of new territory, but there must be enough users of roads in any given district to make it worth while to expend the amount of money it costs to make them. Every road builder knows that the elements have a more deteriorating influence than that which comes from traffic. Obviously, a well-built road on the Maricopa Desert would be worn out by the eroding influence of sand-storms, rather than through traffic. The Glidden path is not nearly so isolated from traffic as the desert mentioned, but it is not believed that there is enough traffic along this route to support a road-building campaign in a large way, in which event we fail to see how the Glidden Tour will better the situation. The tax-payers in Texas will scarcely "shell out" for roads simply because the Glidden Tour went by.

* * *

CARBON REMOVER is probably efficacious; there are various compounds which serve as fluxes, and it is a relatively simple matter to so mix a compound that it will combine with carbon to form carbonic acid. so that the carbon, which in crust formation is unwieldy and sticks to the walls of the cylinders, becomes an element in the carbonic acid gas product and floats away with the exhaust. Some of these fluxes are too highly active to be utilized as carbon removers, because they will not only reduce the carbon in the crust formation, but when they shall have completed this task they will then attack the carbon in the polished surfaces of the cylinder walls.

* * *

GASOLINE, if it is fed into the cylinder in excess, "cracks" in the presence of the heat due to combustion with an insufficiency of oxygen, which is the condition that must abound when the gasoline is in excess. To prevent the formation of carbon, avoid the richness of mixture which produces "cracked" gasoline.



SEEN IN NEW YORK—JUDGING DISTANCE IS JUST AS MUCH OF A PROBLEM FOR THE EXPERIENCED

Dull Week in Detroit Brings Out Three or Four Companies

DETROIT, June 27—The Evans Motor Car Company is being formed by R. H. Evans, ex-president of the Zenith City Telephone Company, of Duluth and Superior, to build a commercial wagon of, perhaps, 1,000 pounds capacity. Mr. Evans has secured the Marine City Iron Works plant at Marine City, Mich., for his plant, but will have his main offices in this city.

At Flint, the L. A. W. Aeroplane Company has been formed, and has the construction of its first machine well under way. This will be a biplane and will carry the L. A. W. rotating engine, made at Providence, R. I. The steering device was designed by W. L. Marr, designer of the Buick machine, who will be connected with the company, as will, also, Z. D. Boning, formerly associated with Count Zeppelin in Germany.

In the Bauer Steel Body Company, organized here last week, the accessory field gains a prominent member. This concern will build, not only steel bodies for commercial and pleasure cars, but also radiators, and other steel parts. The capital stock is $20,000, all paid in. The stockholders and officers are: Charles W. Roseberg, president; M. C. Bauer, vice-president and superintendent; Milton C. Hirschfield, secretary and treasurer. The factory will be located at Warren avenue and Fifteenth street, and will open for active operations July 1.

The Champion Ignition Company, of Flint, has increased its capital stock from $60,000 to $100,000.

The Lincoln National Bank has made application to the United States Comptroller for a charter. The bank is to have a capital of $500,000 and a surplus of $100,000. Many prominent and well-known members of the trade are interested, among whom are: Frank Briscoe, president Briscoe Mfg. Co.; E. S. George, proprietor Standard Auto Company; E. A. Skae, president Gommer Mfg. Co., manufacturing steering gears, etc.; Homer Warren, president Warren Motor Company, etc.

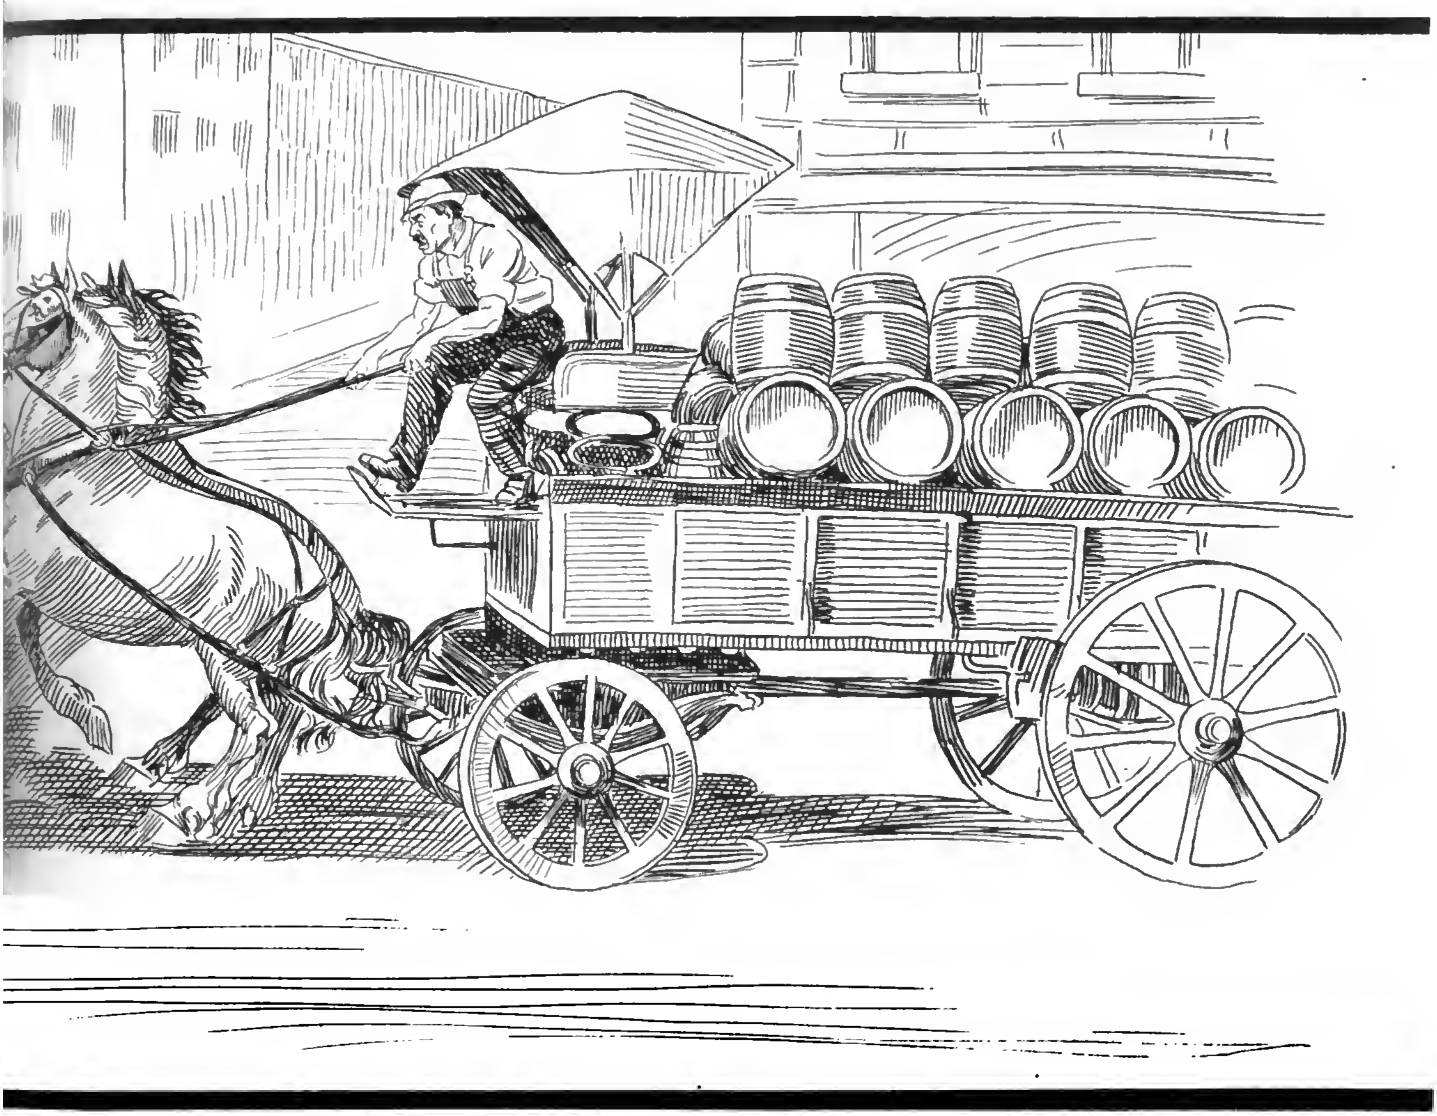
The town of Dearborn is also to have a new bank, incorporated as the Dearborn State Bank. The new concern has purchased the assets of the D. P. Lapham private bank.

The factory of the Sibley Motor Car Company, out at the West End, has been finished and the company is now moving in. This is a large one-story structure, located at Solvay and Mackie avenues. The company is placing on the market a four-cylinder runabout, known as the Sibley 20, to sell at $900.

Sixty-eight thousand dollars is the valuation placed on the new factory of the Regal Motor Car Company, in the building permit.

This unprecedented amount of building and the consequent expansion of the various factories has kept the help problem more to the fore than never before. Good workmen are becoming scarce, despite what other trades characterize as ruinous wages.

Third on the list of Detroit's municipal fire wagons is the machine which has just been accepted and placed in service at



AUTOIST AS LEARNING TO DRIVE IS TO THE BEGINNER—LEARN TO JUDGE DISTANCE

Hose Company Number One, Wayne and Larned streets. This, like its successful predecessors, is a combined chemical and hose wagon.

Great preparations are being made to entertain the Elks, during their convention here the week of July 11. A big automobile reception has been planned for July 15, which the committee in charge is attempting to make the largest automobile affair ever held, both in point of number of cars in line, and in superiority of decorations. To add incentive to the latter, the following prizes have been announced: Sweepstakes prize, silver cup, gold lined, 30 inches high for the best decorated car in the parade; ladies' prize, iced tea set, silver tray and complete cut glass outfit, for the best decorated car driven by a lady; gasoline pleasure cars, first prize, chest of silver; second prize, silver punch bowl; third prize, complete automobile picnic hamper; electric pleasure cars, first, chest of silver; second, cut-glass punch bowl; third, cut-glass water set; comic division, first, Tiffany electric lamp; second, gold scarf pin and cuff link set; third, four gold-plated spark plugs; commercial division, first, gold-lined silver cup 25 inches high; second, gold-lined silver cup, 22 inches high; third. gold-lined silver cup, 18 inches high. Only one of these prizes can be won by any one car. In addition, the Hudson Motor Car Company has offered prizes totaling $50 in value for the best decorated Hudson cars in line, and it is expected that other car makers will follow suit.

Saturday saw the return home of the Regal Plugger, after traveling some 22,000 miles. The car was welcomed by a truck containing a brass band, and a cavalcade of nearly 100 Regal cars and many others. This car, bedecked with labels from all over the United States, has been placed on exhibition in the local sales agency on Woodward avenue.

Another new company entered the local field yesterday, when the Walker Motor Company incorporated with $150,000 capital. The principal stockholders are: G. S. Grantlung, John E. Armstrong, and Thomas E. Morehead.

The latest addition to the industry here is the Bower Roller Bearing Company, of Dayton, O., which is to give up its Ohio home. For this purpose, the company has reincorporated under Michigan laws with a capital of $250,0000. The officers are: R. F. Bower, president; C. H. Heller, secretary.

The E-M-F Company has purchased a tract of land, comprising a total of five acres in Pontiac, fronting on Grove, Baldwin and Howard streets, and lying along the Pontiac, Oxford & Northern Railroad, adjoining the property of the Monroe Mfg. Co., in which the E-M-F Company owns a controlling interest. On this land a large body-building plant to employ 1,000 men will be erected, work starting this month. The present wooden buildings of the Monroe company will be torn down and replaced by brick structures, which will be strictly fireproof. When the new buildings are completed the top department, now housed in the old phaeton building on Willow street, will be removed to the new plant.

From the same city, Pontiac, comes the announcement of the formal transfer of the Welch Motor Car Company, with its plant, good will, and all assets, to the General Motors Company. While it has been generally understood that the Welch company was one of the General Motors components, the formal transfer has just been made.

S. A. E. Plans Important Summer Meeting

Detroit, June 27—The summer meeting of the Society of Automobile Engineers will be held in Detroit, July 28-30. As a result of the active campaign that is being made, this society is occupying an important position in the automobile industry. The July meeting will be the largest and most interesting in the history of the organization, owing to the feeling throughout the membership that under energetic administration, much of the work which should be undertaken by the S. A. E. will be carried to a successful conclusion.

The local Detroit committee on the meeting is constituted as follows: Howard E. Coffin (ex officio), H. W. Alden, chairman, George W. Dunham, Russell Huff, H. M. Leland, F. E. Watts, E. T. Birdsall, A. P. Brush, F. H. Floyd, G. M. Holley and G. E. Merryweather. Various sub-committees are made up of members of this committee.

The program for the different sessions of the convention has been framed as follows:

Thursday, July 28—Morning, business session; afternoon, reading and discussion of professional papers; evening, society dinner, and reading and discussion of professional papers.

Friday, July 29—Morning, visits to manufacturing plants; afternoon, lunch on a yacht, and reading and discussion of professional papers; evening, visit to Light House Inn, participated in by the ladies attending convention.

Saturday, July 30—Morning, reading and discussion of professional papers; afternoon, visit to new Michigan Central Railroad tunnel.

The proposed list of Detroit manufacturing plants to be visited includes the following: Cadillac Motor Car Company, Packard Motor Car Company, E. M. F. Company, Chalmers Motor Company, Burroughs Adding Machine Company, Aluminum Castings Company, Gear Grinding Company, Detroit Steel Products Company, Timken-Detroit Axle Company.

"Little Glidden" Has Thirty-eight Entries

Minneapolis, June 27—Dates for the second annual endurance run for the Minnesota State Automobile Association's prizes are set definitely as July 22 to 27.

The first day's run will be from St. Paul to Mankato, 168.2 miles; the second day's, Mankato to Sioux Falls, 172.2 miles; the third day's, to Redwood Falls, 168.8 miles, and the fourth day's to Minneapolis, 154 miles; total, 658.2 miles.

Officials selected are as follows: Dr. C. E. Dutton, Minneapolis, referee; C. H. Harrington, St. Paul, pilot; W. E. Roby, Minneapolis, chief observer; L. A. Wood, St. Paul, chief checker; Frank M. Joyce, Minneapolis, superintendent of non-contestants; C. F. Philip, St. Paul, superintendent of arrangements; Howard Kahn, St. Paul, publicity agent.

Grand Circuit Meet at Louisville

Louisville, June 27—America's Grand Circuit of auto races will be opened in Louisville Friday and Saturday, July 8 and 9, at Churchill Downs. Manufacturers and star drivers as well as the sport-loving public are showing the liveliest interest in the details of the coming meet, which will be under the management of Homer C. George and W. H. Wellman. The circuit includes: Cincinnati, Columbus, Detroit, Pittsburg, Washington, Baltimore, Providence and Boston.

The local program provides eight races daily ranging from five to twenty miles. Along with the professional events are local races, one at five miles for the Louisville championship and the other a five-mile handicap. In these events only local cars and driven by residents of the city will be allowed to start. Handsome trophies are offered. On the second day a race will be run open to all cars in Kentucky, Ohio and Indiana to give amateurs from those States an opportunity to meet the local flyers.

Offers Blue Book as Prize

Syracuse, N. Y., June 27—At a meeting of the Automobile Club of Syracuse, held Thursday, twenty-three new members were elected, giving a total of 530. The ambition of the officers now is to raise this total to 700 before January 1, and they are confident that it will be done. The weeks preceding the State Fair auto races are expected to be fruitful ones.

The club has offered prizes to the members bringing in the most recruits. For the best record in any month there will be awarded a copy of the 1910 Blue Book.

Brooklyn Dealers Plan Run

Announcement is made by the members of the Brooklyn Motor Vehicle Dealers' Association that they are to hold a two-day reliability contest on Long Island during the latter part of July. The contest will be in the form of a tour, approximately averaging 200 miles for each day. It is not intended to be a pleasure tour but a strenuous test. Aside from the contesting division there will be a tourist section, in which contestants will compete in secret time. Fifteen entries are assured, although entry blanks have not as yet been issued.

More Prizes in Cobe Trophy Race

The Bosch Magneto Company announces that it will award cash prizes amounting to $600 to the first three cars in the Cobe Trophy race to be held July 4 on the Indianapolis Speedway. The purse will be divided, $300 to the winner; $200 to the second, and $100 to the third. The proviso and only condition imposed is that the cars so rewarded shall be fitted with the Bosch Magneto.

EXAMPLES OF RAILROAD TRACK WORK INDULGED IN BY PARTICIPANTS IN THE GLIDDEN TOUR, AT TERRAL.

German Air Line, with Through Sleeper

Travel by schedule through the air will be instituted in the near future when the liner Deutschland, of the German Airship Navigation Company, commences its regular runs from Dusseldorf, through the Rhine Valley. The airship, a rigid dirigible 482 feet long by 48 feet beam, which was formerly known as Zeppelin VII, has already made her final trial trip over the 300-mile route. The trip was made at about the speed scheduled for the regular trips. Conditions were ideal throughout the undertaking, but as the summer season in Germany usually contains only a few bad days, the weather enjoyed is not considered unusual.

The meteorological records show that only 43 days in each year may be regarded as stormy in Germany, and almost all of these occur in the winter. The Deutschland is intended to make the 300-mile trip in less than nine hours. The ship is equipped to carry twenty passengers and sleeping and eating accommodations for that number have been made on board. An elevation of 400 feet will be maintained during the flights. Powerful wireless instruments have been installed on the air cruiser. The passenger tariff, which has been issued to the German public, ranges from $25 for the shortest trip between stations to $125 for the full route from Dusseldorf to Friedrichshafen.

Changes in Bay State Motor Law

Boston, June 27—The members of the Massachusetts Legislature have packed up their things and gone home, and as a legacy have left a few changes in the motor law, which some of them believe are meritorious. They wiped out the section requiring chauffeurs to carry badges. They allowed figures used on the rear of motor cars to be elevated 48 inches from the ground instead of 36. They enacted a reciprocity clause, so that now it matters not how many days another State allows Massachusetts' motorists to use its roads, the visitor from outside has only ten days in any one calendar year to operate in the Bay State, while those States that have restrictions will find their motorists restricted to less than that number, to correspond to the days allowed others in the State they come from.

Another piece of legislation was the changing of the clause relative to sounding the horn at crossroads. The motorists were in favor of abolishing this restriction, which has caused hundreds of needless arrests. However, the legislators provided that out in the country on passing a corner where the view was not obstructed the horns need not be blown. But in the cities it provides that they still be blown, but that no bell, horn or other device for signalling, shall be so sounded as to make a harsh, objectionable or unreasonable noise. Nor shall any driver permit an unreasonable amount of smoke to escape, or make any unnecessary noise. The changes go into effect July 10.

Maryland Motor Law in Effect July 1

Baltimore, Md., June 27—All the provisions of the Swann Motor Vehicle Law, recently passed by the Maryland Legislature, will go into effect Friday. All chauffeurs' licenses and certificates of registration under the old law will have to be exchanged for operators' licenses. All the motor-car records heretofore kept by the Secretary of State will be turned over to Commissioner of Motor Vehicles John E. George. The following fees must be paid for licenses:

Class A—Six dollars per annum for each motor vehicle with a rating of 20 horsepower, or less; $12 for one with a rating of more than 20 and under 40, and $18 for one with a rating of more than 40 horsepower.

Class B—Three dollars a year for each certificate of registration of a motor vehicle used only for transportation of merchandise.

Class C—One dollar and eighty cents a year for each certificate of registration for a motorcycle.

Class D—Twenty-four dollars a year for each certificate assigning a general distinguishing number or marks to a manufacturer or dealer in motor vehicles other than motorcycles.

The rate of speed shall not exceed 12 miles an hour in the thickly settled or business section of cities, etc.; 18 miles in the outlying districts or more than 25 miles in the open country.

Only such horns for warning signals can be used as are operated by hand pressure.

Munsey Pathfinder Making Progress

Bretton Woods, N. H., June 27—The E-M-F Pathfinder, which is laying out the route for the Munsey historic tour, reached this place Saturday.

The car is doing well. Tom Skeggs, who drove it in laying out the "Little Glidden" route this year, is at the wheel. The other members of the party are F. J. Byrne, Harry Ward and E. G. Lynch, of Lazarnick's staff.

During the coming week the pathfinders will lay out the route from Bretton Woods to Burlington, crossing Lake Champlain and continuing down to Lake George, Saratoga, Binghamton and Cooperstown, N. Y.

South Bend Club Elects Officers

South Bend, Ind., June 27—The South Bend Automobile Club elected officers at a meeting held at the Oliver Hotel Friday evening. The following were chosen: Walter Hager, president: Arthur L. Hubbard, vice-president; Jacob Woolverton, treasurer, and A. H. Cushing, secretary. The officers will co-operate with a board of governors to administer the affairs of the club. The board is composed of L. P. Hardy, Edwin Witwer and Dr. George V. Neinstedt.

Getting Ready for Galveston Races

GALVESTON, TEX., June 13—Automobilists from all over Texas, and from the North and East as well, are looking forward to the races to be held on Galveston beach, August 3, 4 and 5, as the motor car event of the summer in this State. The president of the Texas State Automobile Association, J. W. Munn, of Galveston, who is also the director for the beach races here, is now making a pathfinding tour of the State, stirring up interest and securing as large an entry list as possible. Encouraging reports from him are being received in Galveston. He has visited Houston, San Antonio, and Austin, and will go to Dallas, Waco, Fort Worth, and Beaumont before he returns.

The events and prizes for the three days are as follows:

First Day, Aug. 3

Event No. 1: Class B, division 2-B, twenty miles; entrance, $10; prizes, first $100, second $25.

Event No. 2: Class B, division 4-B, thirty miles; entrance, $10; prizes, first $150, second $50.

Event No. 3: Class B, division 3-B, twenty miles; entrance $10; prizes, first $100, second $25.

Event No. 4: Class D, free-for-all, fifty miles; entrsnce, $15; prizes, first $200; second $50, third $25.

Second Day, Aug. 4.

Event No. 5: Class B, division 5-B, twenty miles; entrance, $10; prizes, first $150, second $50.

Event No. 6: Class B, division 2-B, ten miles; entrance, $5; prizes, first $75, second $25.

Event No. 7: Class E, special one mile flying start for beach record; entrance $5; each entrant allowed two trials; prize $100.

Event No. 8: Class B, division 3-B, ten miles; entrance, $5; prizes, first $75, second $25.

Event No. 9: Class B, division 4-B, ten miles; entrance $5; prizes, first $75, second $25.

Third Day, Aug. 5.

Event No. 10: Class D, free-for-all, 200 miles; entrance $25; prizes, first $500, second $100, third $50; for best time first 50 miles $100, for best time first 100 miles $150.

The course is to be a five-mile straightaway and return for all races except the 200-mile event, which will be run over the ten-mile course. The course will be roped off for quite a distance, and police patrol will be provided to see that spectators do not get in the way of the racers. A paddock is to be constructed to protect the cars from any rain or bad weather. The beach, which under normal conditions is about 100 feet wide, is in excellent condition this summer, and some fast records are expected.

Capt. Munn, of Galveston, has entered his 40-horsepower National; S. H. Weis, of San Antonio, an 80-horsepower Chadwick; G. A. C. Halff, of San Antonio, a 60-horsepower Stoddard-Dayton, to be driven by Dehymel. Many other entries are looked for within the next few weeks. Entries may be made until July 28. The races will be run under the rules and by the sanction of the A. A. A.

Central Ohio Automobile Items

COLUMBUS, O., June 27—The Ohio General Assembly adjourned recently without amending the Ohio automobile law in the least particular. It was through the efforts of Secretary of State Carmi A. Thompson, Attorney-General U. G. Denman and State Registrar of Automobiles Fred H. Caley that no changes were made in the law.

The Automobile Club of Stark County (Ohio) is arranging for a club run to start July 9 to extend as far as Detroit. It is planned to touch Akron, Cleveland, Toledo, Sandusky and other cities in the run. Eight cars have already been pledged and other entries are expected to be in later.

First Day of St. Louis Run Shows Sixteen Clean Scores

ST. LOUIS, June 30—The three-day reliability run for the St. Louis *Star* trophy, under the auspices of the St. Louis Automobile Manufacturers and Dealers' Association, started Tuesday morning with 29 contestants in the lists. The Buick pilot car, loaded with confetti, left St. Louis Star square at 5 A. M., and an hour later the first of the contestants was sent away, the others following at 1-minute intervals in their order.

The first day's run took the contestants from St. Louis through St Charles, Wentzville, Harvester, Cottlesville, Darden, Flint, Moscow Mills, Troy, Eolia, Clarksville, Louisiana, New London and Hannibal, a distance of 141.1 miles.

The second day's run was from Hannibal through Palmyra, Monroe, Hunnewell, Shelbina, Clarence, Macon, Excello, Jacksonville, Moberly and to Mexico, distance, 143.3 miles. The third day's run will end at St. Louis, the tour passing through Wellsville, Montgomery, Jonesburg, Warrenton, Truesdale, Middleton, Wright City, Forestel, Wentzville, Darden, Cottlesville, Harvester and St. Charles.

The officials of the run are: Referee, J. D. Perry Lewis of the Halsey Automobile Company; starter, Robert E. Lee; pilot, W. R. Crusoe. The checkers at controls are Samuel Breadon, Charles E. Mitchell, and H. W. Blodgett. The contest committee, Frank R. Tate, John H. Phillips and C. E. Mitchell.

At the conclusion of the tour, Thursday evening, the cars finishing will be driven to the official garage, where the final inspections will be made. The *Star* trophy, a handsome cup, will be awarded to the car which shall have finished with the most nearly perfect score. Should two or more cars tie for the highest score, the contest committee will arrange a special run for final decision, over the same or a harder course.

In addition to the touring car and runabout classes, the contestants are listed in four divisions—Cars valued at $3,500 or over, second, at $2,001 to $3,499; third, at $1,001 to $2,000; fourth, at $1,000 and under. A 15-mile schedule is observed for cars of the first division; 14-mile for second division; 13-mile third; and 12-mile fourth. The first day's score follows:

No. Car	Entrant	Driver	Score
1—Overland	C. E. Goldthwale	C. E. Goldthwale	1,000
2—Moon	Eli Collutte	R. Weinbert	971
3—Buick	Frank De Laney	C. H. Blake	1,000
4—Maxwell	Val. Heinrich	G. H. Houghton	998
5—Oldsmobile	B. K. Olin	John Grenninger	Dis.
6—Mitchell	C. M. Barnard	Marcus Wolff	990
7—Oldsmobile	W. B. Fewell	T. A. Goodman	1,000
8—Cadillac	W. F. Bagnell	W. F. Bagnell	1,000
9—Moon	E. J. Moon	Ed. Moore	975
10—Rambler	Will Smythe	J. H. Ramsden	Dis.
1—Dorris	J. T. Rumble	Ed. Gadsey	1,000
12—Moon	Mathew Blavalt	Ed. Gillespy	998
13—Columbia	E. E. Ernest	J. C. Graham	1,000
14—Buick	James Ladd	Charles Berkley	1,000
15—Everitt	A. J. Whittaker	Frank Morris	994
16—Mitchell	J. H. Little	W. F. Young	993
17—Ford	H. L. Bagley	Dr. H. A. Upshaw	1,000
18—Pope-Hartford	Walter Saigeon	Fred Schmidt	999
19—Haynes	Carl Williams	Carl Williams	1000
20—National	C. Merz	H. S. Reed	1,000
21—Interstate	H. M. Paine	H. M. Paine	1,000
22—Buick	N. C. Tuxbury	H. Paul	1,000
23—Stearns	J. M. Dunwoodie	J. M. Dunwoodie	1,000
24—Hupmobile	Roy Anselm	J. A. Hutchinson	975
25—Dorris	J. E. Baker	K. Funsten	1,000
26—Marmon	Ed. Holthaus	Ed. Holthaus	977
27—Amplex	H. L. Schure	H. L. Schure	1,000
28—Moline	W. von Steiger	J. E. Foland	1,000
29—Stearns	D. B. Brownback	D. B. Brownback	994
30—Haynes	A. A. Franklin	A. A. Franklin	886

In addition to the pilot car and the contestants, there is a Dorris car for the officials and a Standard Six for representatives of the press.

Live Problems Discussed at A. L. A. M. Meeting

At a well-attended meeting of the Association of Licensed Automobile Manufacturers, yesterday, it was reported that the final hearing on the interlocutory decree before Judge Hough in the Ford and Panhard cases has been definitely fixed for the morning of July 19. The testimony on both sides in the supplemental bills and answers has been closed, and now only awaits the hearing of the application for the entry of decrees.

Aside from routine business, there was a general discussion of trade conditions, which showed a continuance of the healthy demand for motor cars, that are now such an essential part of American life, and particularly a strong demand for freight-carrying cars. Reports and figures of the manufacturers indicated very clearly the reason why bankers and railroad men have been decrying the buying and using of automobiles, as the motor-car builders say that many people are buying motor cars now instead of putting their money into Wall Street stocks with their usual uncertainty.

The executive committee of the association held its meeting on Tuesday, while there was also a meeting of the directors of Association Patents Company, at which Alfred Reeves was elected secretary and treasurer in the place of Coker F. Clarkson, who resigned to become secretary of the Society of Automobile Engineers.

President Clifton presided, and among those in attendance at the board meeting were: James Joyce, American Locomotive Company; John S. Clarke, Autocar Company; G. A. Lambert, Buckeye Manufacturing Company; C. C. Hildebrand, Chalmers Motor Company; H. W. Nuckols, Columbia Motor Car Company; M. S. Hart, Corbin Motor Vehicle Corporation; R. M. Brownson, E-M-F Company; G. H. Stilwell, H. H. Franklin Manufacturing Company; Elwood Haynes, Haynes Automobile Company; F. O. Bezner, Hudson Motor Car Company; G. A. Matthews, Jackson Automobile Company; A. N. [illegible], Knox Automobile Company; S. T. Davis, Jr., Locomobile Company of America; S. Regar, Lozier Motor Company; Horace DeLisser, Maxwell-Briscoe Motor Company; Wm. T. White, Mercer Automobile Company; Wm. E. Metzger, Metzger Motor Car Company; A. C. Newby, National Motor Vehicle Company; C. C. Hanch, Nordyke & Marmon Company; C. R. Hatheway, Oakland Motor Car Company; L. H. Kittredge, Peerless Motor Car Company; Charles Clifton, Pierce-Arrow Motor Car Company; George Pope, Pope Manufacturing Company; R. M. Owen, Reo Motor Car Company; Geo. J. Dunham, Royal Tourist Car Company; G. E. Mitchell, Alden Sampson Manufacturing Company; R. H. Salmons, Selden Motor Vehicle Company; R. F. York, F. B. Stearns Company; E. L. Thomas, E. R. Thomas Motor Company; Windsor T. White, Waltham Manufacturing Company; Geo. W. Bennett, Willys-Overland Company; Thos. Henderson, Winton Motor Carriage Company, and Alfred Reeves, general manager.

Seventeen Starters in Denver Post Run

CHEYENNE, WYO., June 28—Seven perfect scores were made in the first of the five days' reliability contest promoted by the Denver *Post*, which started this morning from Denver. The Renault, Studebaker, E-M-F, Jackson, Buick, Rambler and Haynes were in this category, while those penalized included: Reo, 3; Flanders, 103; Hupmobile, 19; Regal, 10; Brush, 8; Gleason, 111; No. 15, Page, 18; No. 16, Page, 13; Firestone-Columbus, 49; Apperson, 10. The Gleason was assessed 100 points for careless driving. To-night it was raining hard, and it is indicated that the run to-morrow back to Denver, a distance of 115 miles, will be a tough one. Thursday the run goes from Denver to LaJunta, 181 miles, and Friday from LaJunta to Hugo, 200 miles. Saturday the cars return from Hugo to Denver, 208 miles.

Winton Continues Sixes for 1911

(*Continued from page* 1167)

ternal expanding brakes. In addition to the torsion rod as shown, there are radius rods extending from the extremities of the axle to the chassis frame.

(J)—Left hand side of the six-cylinder motor showing the carbureter in place, and how the intake manifold extends from the carbureter orifice up and over the cylinders, terminating in Winton design of distributing manifolds, so arranged as to deliver an equal weight of mixture to the respective cylinders. The piping of the self-starting system may be plainly seen in this view, and priming cocks are so placed that they are accessible. The carbureter is above the line of the chassis frame, so that it is accessible.

(K)—View of the power plant, looking down from a position at the left and rear of the chassis, showing the method of suspending the motor, the relations of the parts, notably the control system, also the foot pedals for the clutch and brakes, and the equalizer, by means of which the brakes on the two wheels act in unison. The side levers here come into view, and the mechanism which is employed in the selector system is in a dust-proof housing at the right side of the transmission gear case. The offset at the narrowing point of the chassis frame is laterally supported, and the foot boards are attached to pressed steel brackets.

Choices Given to Patrons for 1911

The choices which will be given the Winton patrons for 1911 are as follows:

Car complete with touring, runabout, or toy-tonneau body, $3,000; the torpedo body will be furnished at $250 more, and the car complete, with a limousine body, will be $4,250; with a landaulette body $4,500; the chassis without body will go for $2,750; and the touring body separately is listed at $500, which is also the price of the runabout and toy tonneau body; a separate limousine body may be had for $1,500, and the landaulette at $1,750. One of the Winton ideas for this year is to offer the chassis with two bodies, and if the purchaser elects to take a limousine and touring body, the price will be $4,500, or, if the selection is a landaulette and touring body, the price will be $4,750; the touring body, however, seats five, and if a seven-passenger touring body is ordered instead, it will be at an extra of $250. The equipment, which is listed as regular, includes two gas head lamps, two oil side lamps, and one oil tail lamp, gas tank or generator, horn, and full set of tools. A locker is provided under each seat, but the front seat locker is of the drawer type, and is partitioned to accommodate the tools. The color options are royal purple, blue, green, gray, maroon, and red. The finish is up to the customary Winton standard, which includes layer upon layer of the finest paint and varnishes, sufficiently to obtain the highest possible carriage excellence. This, together with the straight line style of design of body work, accounts for the particular distinctiveness which draws attention to Winton automobiles on the road.

Peculiarities of Modern Non-Charring Brake Linings

(*Continued from page* 1176)

fer to take chances rather than to give the subject, in the light of a concrete application, the real attention it deserves, with the result that brakes, for illustration, are not always the success that they would have users believe.

The Renne experiments, dating back to 1829, still offer information to the designer who has to deal with unlubricated friction, as when brakes are being designed. The conclusions then reached, which have not been disproven since that time, may be restated as follows:

(A)—The law of solid friction differs with the character of the rubbing bodies.

(B)—With wood, metal, and stone, within limits of abrasion, friction varies only with pressure, being independent of extent of surface, time of contact and velocity of rubbing.

(C)—With fibrous materials, friction is increased by increased extent of surface, and by time of contact, but is diminished by pressure and speed.

(D)—The limit of abrasion is determined by the hardness of the softer of the two rubbing materials.

(E)—Friction is greatest with the soft and least with the hard materials.

It is the condition (C) that is most interesting at the present time, owing to the use of brake linings of asbestos, which are much used, or cork inserts, which follow the same law. The first conclusion to reach is: if a set of brakes of the metal to metal sort will not give satisfaction, it is a positive crime to place fibrous materials under identically the same conditions, which limit surface, increase pressure per unit of area, and accomplish all the other crimes of designing which lead up the narrow alley-way to the goal called failure.

The law says that the fibrous linings will do the best work, (a) with increased extent of surface, (b) by time of contact, but the law also states, (c) ability decreases with pressure, and, (d) with speed of rubbing.

Considering the laws which govern when fibrous materials are employed, what is wanted is:

(A) The greatest possible surface of the linings.

(B) The maximum time of contact.

How is this to be accomplished? Readily, provided the brakes are designed with a large surface, and are placed on the road wheels of the automobile. It must be remembered that as the wheels (on which the brakes are placed) run slower, the time of contact will be longer.

Cork inserts work with excellent satisfaction when the brake surface is somewhat over 500 square inches on a car which weighs upward of 3,600 pounds.

It would seem as if it will be within the range of possibilities to fix the conditions under which brakes are to work, naming the several conditions as, pressure per square inch for the several available materials, speed of rubbing, which regulates the diameters of drums, taking into account the location and spindle speed which follows.

Glancing at the laws which seem to hold, it is rendered apparent that the same character of materials should not be used at all points, under widely varying conditions. If the speed of rubbing is high, and the pressure per square inch is augmented to exceed that which is good practice for fibrous material and cork, it remains to be seen whether or not the brakes will be quite satisfactory.

For metal to metal, it is important to note that the coefficient of friction decreases with speed; the law is as follows:

"The coefficient of unlubricated friction decreases materially with velocity, is very much greater with minute velocities of O +, falls very rapidly with minute increases of such velocities, and continues to fall with decreasing rapidity with higher velocities up to a certain point, following closely the law which obtains with lubricated friction."—*Wellington.*

As an indication of the rate of decrease of the coefficient of friction of metal to metal, all that the occasion demands for the moment, is to quote an account of the adhesion of steel tires sliding on steel rails. An account is given as follows (Westinghouse & Galton):

Speed in miles per hour....	10	15	25	38	45	50
Coefficient of friction......	0.11	0.087	0.080	0.051	0.047	0.040

These speeds are all within the practice as it obtains in brake-shoe work, and granting that geographical location will scarcely alter the coefficient of friction, it is readily seen that the brakes are least capable just when they were the most in demand.

Harris' Cadillac Wins Delaware Sealed Time Run

WILMINGTON, DEL., June 27—Coleman B. Harris, in a 30-horsepower Cadillac touring car, was the winner of the sealed time run of the Delaware Automobile Association, from Wilmington to Oxford, Pa., and return, a distance of 72.6 miles, which took place last Saturday. His time was 4 hours and 14 minutes, while the sealed time was 4 hours and 19 minutes. Mr. Harris had the least number of penalizations. By winning the run Mr. Harris will receive a handsome silver loving cup, offered by the association.

Courtland E. Pierson, in a 30-horsepower E-M-F touring car, was second, and John B. Bird, in a 20-horsepower White steamer, was third, but their time was not learned, the run committee of the association, which computed the time, declining to give out any information on the subject, regarding the details, except as to the winner.

While the number of contestants was not large, only eleven entrants starting, it was full of interest, from the fact that the weather was ideal, but also because of several muddy places in the road, in Pennsylvania, there were some unpleasant incidents to record. All got through the bad places, however, without mishap, and none had any trouble in following the route, which was indicated by confetti distributed by Bissel C. Crommon and Charles G. Guyer in the pilot car, which started an hour in advance of the beginning of the run. The start was made from the court house in this city, at 11 o'clock, the cars checking out in the order given in the table below.

There were four checking stations, which were unknown to the entrants. They were as follows: London Grove, A. K. Barker: Oxford, William Stanier; Avondale, Thomas T. Weldin; Lamope, John B. Martin. All of the entrants finished except J. Danforth Bush, who took a run off the course, for the purpose of visiting Elkton, Md. The run was under the management of a committee comprising A. B. Hazard, chairman; Charles G. Guyer and William Stanier. The entrants finished in the following order:

Checking Out the Cars, A. B. Hazard, Chairman of Run Committee

No.	Name of Car	H. P.	Entrant	Driver	Time
1	White Steamer	20	John B. Bird	John B. Bird	4.24
8	Cadillac	30	Coleman B. Harris	Coleman B. Harris	4.14
7	E-M-F	30	C. E. Pierson	C. E. Pierson	4.25
9	Maxwell	12	C. G. Cann	C. G. Cann	4.25½
5	Stanley Steamer	20	T. C. Marshall	T. C. Marshall	4.30
2	Peerless	38	E. M. Pennypacker	E. M. Pennypacker	4.36
6	Stoddard-Dayton	40	Dr. J. C. Fahey	Frank Chadwick	4.36
11	Stevens-Duryea	24	John R. Wilson	John R. Wilson	4.36½
10	Apperson	30	H. D. Ross	A. M. Otteen	4.41½
4	Stevens-Duryea	24	Wm. C. Corey	Wm. C. Corey	4.55
3	Courier	22½	J. Danforth Bush	J. Danforth Bush	Did not finish

Delaware Achieves Reciprocity

WILMINGTON, DEL., June 27—Automobilists in Delaware now enjoy reciprocal relations with Maryland as well as with Pennsylvania.

This is welcome news to owners of cars in this State, in view of the fact that it is now possible to go to either Philadelphia or Baltimore, or any places in Maryland or Pennsylvania, with Delaware State licenses.

Cars Assembling for the Start at Court House, Wilmington

After considering the subject for three years, the Water Witch Fire Company of this city has given contracts for two automobile fire engines, which are to be delivered the latter part of October or the early part of November.

Virginia Automobile News

RICHMOND, VA., June 27—A test is now being made of methods of laying the dust of the city streets, and the process of the Cincinnati Good Roads Company is being tried. The driveways of several of the city parks are being sprinkled with asphalt oil, and the results are expected to prove highly satisfactory. In case these thoroughfares are free from dust as the result of the oil, the thoroughfares of the city, especially the main ones, will be treated and kept in a dustless condition. This move has been agitated for many months by autoists of Richmond, and Councilman Don Levy has fought for it for over two years, but with indifferent success. Now the prospects are bright for the success of the movement.

The license for the first automobile ever built in Richmond was issued to J. A. Grassberger on Friday, and the machine is now in evidence on the city streets. It is a four-seated roadster, of 18 horsepower. The machine was manufactured as an experiment, and it is stated that a regular automobile factory will be started here by an organized company soon, though definite steps have not yet been taken.

To Wind Up Electric Vehicle Company

Judge Joseph Cross, of the United States Circuit Court of the New Jersey district has issued a rule on the creditors and stockholders of the Electric Vehicle Company to show cause, June 27, why the report of the receivers should not be accepted and its recommendations as to distribution of moneys, granted. The receivers have $22,892 in hand. The chief clause of the report is a petition that the sale of the Electric Vehicle Company's business to the Columbia Motor Car Company be ratified, confirmed and approved.

Studies Involving Refinements of Gasoline Equipment

(*Continued from page* 1181)

When a motor stops and the ignition system proves to be in good order it is not so difficult to deal with the problem if the interruption is permanent. It then becomes necessary to find out (a) if there is any gasoline in the tank, (b) if the quality of gasoline present is good enough to use, (c) if the carbureter is so adjusted that the gasoline is in the right proportion, (d) if the flow of gasoline from tank to carbureter is stopped.

It is not at all difficult to find out if there is gasoline in the tank. Take the filler cap off, and put a measuring stick in through the orifice and upon withdrawing the same note the height of the wetted surface. If the carbureter floods it is of course a sign that the flow of gasoline is not properly regulated by the needle valve as it is controlled by the float. The first thing to do under such conditions is to note if the needle-valve seat needs tightening; if it does, it is then necessary to find out if the buoyancy of the float is normal. The excess of gasoline must be stopped, no matter to which of these causes it is due, before the mixture can be relied upon to conform to the demands of the motor.

If the gasoline flow is insufficient it will be due to one of the causes above named, and if it is found that there is a quantity of suitable gasoline in the tank, but that it does not flow to the carbureter, it is a self-evident fact that an obstruction in the passageway at some point will be at the foundation of the trouble. In dealing with a new automobile it is always well to look for obstructions which may come in the form of a drop of solder, which frequently flows from the joints which are being sweated, to some restricted lodging point, as the orifice through which the gasoline enters. By taking the system apart and blowing through each member the one having the obstruction will be discovered. Referring to Fig. 3 which is of an auxiliary tank on the dash, which receives its gasoline under pressure from the tank, it will be observed that the gasoline enters from the tank to the filter, passes through the same, and then to the float chamber or main portion of the tank, under the control of a needle valve, which is lifted through the buoyancy of a float. The filter is so contrived that it may be screwed out, examined, and cleaned if necessary. This operation should be performed at reasonably frequent intervals, and a water basin should be provided in the bottom of the tank so that the accumulation of water, some of which obtains in gasoline, may be drained off as the exigencies of service would demand.

Fig. 4 is a much more promising design of an auxiliary tank for the dashboard, because it is so made as to eliminate the necessity of using a wire filter, which is bound to be more or less of an obstruction, although in this case means are afforded for draining off the water as it accumulates without running the risk of having the water serve as a plug for the gasoline passageways. In this design the gasoline raises up and then passes in through the orifice which leads to the needle-valve seat, and the water, if any is entrained, will lie on the bottom of the well until it is drained off through the water drain. A large inspection cap is provided at the top; it has a leather packing, which makes it easy to screw the cap to tightness, even by hand pressure, although a large hexagon head is available in case wrench tightness becomes necessary. At the bottom of the tank, where the gasoline flows out, there is a standpipe which affords a sufficient water basin by means of the differences in levels, so that clear gasoline will flow through the carbureter and the water will lie in the basin until it is released by opening the drain cock. One of the ideas in presenting this design was to indicate the desirability of making things accessible.

Hughes Signs Anti-Joy-Ride Law

Albany, June 27—Governor Hughes has signed the Toombs bill amending the penal law so as to enlarge the scope of the anti-joy riding law of 1909. The former law provides that "Any chauffeur, or other person, who, without the consent of the owner, shall take, or cause to be taken, from a garage, stable, or other building or place, an automobile or motor vehicle, and operate or drive, or cause the same to be operated or driven, for his own profit, use or purpose, steals the same and is guilty of larceny, and shall be punished accordingly."

The law was found to have loopholes which lawyers found for the clients' benefit and this year it was amended by inserting after the words "shall take," the words "use, operate or remove"; and, again, after the words "or cause to be taken" the additional words, "used, operated or removed"; and then again there is inserted after "place," the words "or from any place or locality on a private or public highway, park, parkway, street, lot, field, inclosure, or space." All of which expands the scope of the law intended to stop the unauthorized use of automobiles by chauffeurs and others.

Miss Phillips, one of the Overland crew, toting a block to repair a broken spring

Motoring Activities in Wisconsin Field

Milwaukee, June 27—Eighteen cars have been entered in the first annual tour of the Wisconsin State Automobile Association for the Milwaukee *Sentinel* trophy, starting from Milwaukee on Monday morning, July 18, and finishing in that city on Friday evening, July 22. Chairman George A. West of the Contest Board expects another eighteen entries, and believes now that more than twenty-five cars will start.

The entries now on file are: Rambler Garage Company of Milwaukee, branch of Thos. B. Jeffery Co., Kenosha, Wis., two cars; Badger Motor Car Company, Columbus, Wis., two cars; The Kisselkar Company, branch of Kissel Motor Car Company, Hartford, Wis., three cars; Buick Motor Company, Flint, Mich. (Milwaukee branch), three cars; Bates-Odenbrett Automobile Company, Overland; Curtis Automobile Company, Reo; Jonas Automobile Company, Cadillac; Johnson Service Company, Milwaukee, Johnson; Franklin Auto & Supply Company, Franklin; Studebaker Automobile Company (Milwaukee branch), one car, and others, if present indications count for anything.

The 1911 pro-

Miss Scott, the other fair Overlander, blocking up the broken spring

Parry, No. 105, nearing Bowling Green, Ky., in the Glidden Tour

duction of Thomas B. Jeffery Company, Kenosha, Wis., will be 2,500 cars, according to announcement just made at the Rambler works. The number is practically the same as in 1910, and the news may cause some surprise.

Thomas B. Jeffery Company was incorporated last week with a capital stock of $3,000,000. Officers are about to be elected by the company.

Eugene O. Edwards, of LaCrosse, Wis., has invented a new type of gasoline motor. The power is obtained by a revolving motion in the cylinder, instead of the conventional piston stroke, and the ports are in the top of the cylinder. The core of the cylinder forms the water-cooling system, the revolving power wheels being outside of this core. The engine is now being tried out in a gasoline launch. The present motor is in the one-cylinder form, but any number of cylinders up to six can be added without rearrangement.

The National Gauge & Register Company, of Minneapolis, Minn., has moved its plant to LaCrosse, Wis., being the first concern to be attracted to LaCrosse by the new industrial association. The company manufactures eight motor-car accessories and specialties, the invention of Edmond E. Hans, vice-president.

The Mitchell-Lewis Motor Company, of Racine, Wis., will build 2,000 more cars for 1910 delivery than originally intended. About thirty-five cars are being turned out every day and the plant will run all summer.

Future Puzzle for St. Peter

Charles Wells, of the photographing firm of Spooner & Wells. has a reputation for self-contained dignity, moderation and temperance and among the things he particularly abhors is profanity in any form. But, notwithstanding his views and reputation, he came mighty close to the line while he was helping to repair one of the tires of the big Peerless machine in which he was a passenger during the endurance run of the New Jersey Automobile and Motor Club.

The "blow-out" occurred near the new country club house, and Mr. Wells had succeeded in inserting a tire iron between the rim and the shoe and was preparing to give it a yank. Something "beat him to it" and with a grunt the shoe slipped back while the iron, twisting from his grasp, struck him on the thumb with a crack that sounded like a "foul-tip."

The dignified photographer writhed in pain while the crew of the Peerless gathered around him sympathetically.

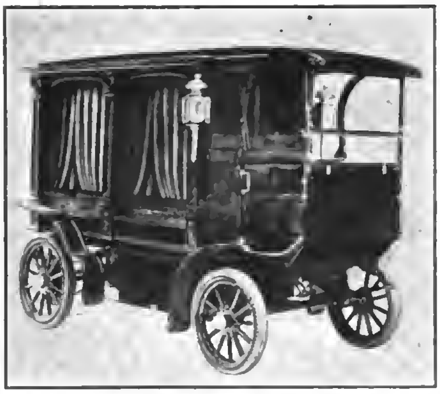
Mr. Wells, with agony distorting his face, shook the injured thumb woefully and to the intense surprise of the crew exclaimed: "Bob jam the jam thing to jell."

After the pain had subsided he triumphantly pointed to the fact that he had used no profane word even under the trying circumstances.

Road Commission Tests Highways

Starting June 28 from Rochester, the New York State Highway Commission, which has been at work for a year in perfecting an organization and in starting road improvements in a practical way, began a two-day tour of Monroe, Wayne, Ontario, Livingston, Alleghany, Wyoming, Genesee and Orleans counties as guests of the Automobile Club of Rochester.

The commission, its deputies, county superintendents and fieldmen, assembled in Rochester for its semi-annual conference Tuesday. The delegates numbered about 200, and the trip over the roads seemed almost as large as a big endurance run, as far as the number of cars engaged is concerned. The trip was undertaken as a road test and demonstration of the value of the work of the commission so far as it has progressed.



The Waverley Electric Hearse—A new and Silent Funeral Car

One of the features of the tour was the use of an unique road map constructed during a preliminary trip over the route, which contained comments on every portion of the road, with criticisms as to construction, material and engineering.

Each evening was devoted to meetings, conferences and entertainments, and the final session was held at Charlotte after the trip had been completed. A general discussion of conditions as revealed on the tour was the feature of the last meeting.

Plainfield Club's Second Climb

Johnston's Drive on Watchung Mountain will be the scene of the second annual hill climb of the Plainfield (N. J.) Automobile Club, Saturday, July 9. A program of eight interesting events has been arranged. Five of them are under "B" classification, according to piston displacement; one is for small cars selling under $800; another is a free-for-all of the widest latitude, and the final race is for New Jersey residents, cars to be driven by amateurs.

The hill is 3,996 feet in length and rises 300.5 ft. with a good imitation of a hairpin turn. The average grade is 7.52 per cent. and the going is of a character to test the capabilities of the best cars on the market.

Cups and medals will be awarded, respectively, to the first and second in each of the events, except for the small car event, in which there is only one prize offered. The entry box will remain open until midnight of July 4. W. R. Townsend, Plainfield, N. J., is secretary of the club.

Nashville News of the Automobile

NASHVILLE, July 27—The newly organized automobile club at Nashville has completed plans for its initial run on July 4 and about thirty cars have entered, with prospects that twice that number will take part. The route goes through Shelbyville, Fayetteville, Petersburg, Lewisburg, Culleeka, Columbia, Franklin. and back to Nashville, a distance of 130 miles.

Robert Rhea left Nashville on June 20 in his E. M. F. thirty for a trip of 2,000 miles. Accompanied by Edward Walsh, he is on his way to Colorado Springs, via St. Louis and Kansas City.

Through the influence of Nashville autoists a considerable amount of oiling of roads is being done around Nashville. Several of the leading pikes have been oiled for several miles. The Harding road has just been prepared for six miles.

Nashville and Memphis automobilists have taken up in a vigorous way a project for a great public road or boulevard from Nashville to Memphis, a distance of about 283 miles. The only way the trip can be made now is over the route followed by the Glidden tour through North Alabama. Of the 283 miles, 123 miles is already good road and 26 miles is being built, leaving 134 miles to be arranged for.

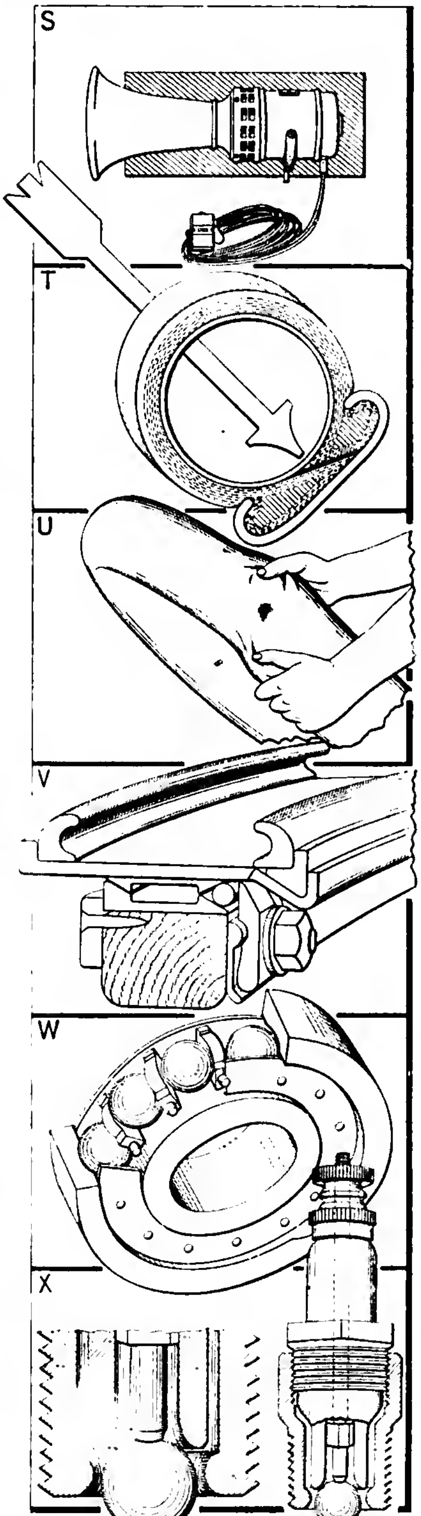
Seen in the Show Window

IN the SirenO (S), which is manufactured by the company of the same name, with offices at 1508 Taylor Building, New York City, the automobile public has a warning signal which, while powerful and far-reaching, in accord with the demands of present-day traffic conditions on street and road, is yet of a sufficient mellifluous and pleasing note as not to jar the sensibilities of the delicately nurtured. It may be had in eight styles and sizes, suitable for the smallest runabout or the largest touring car.

TIRES are conceded to be the most valuable portion of the make-up of the automobile. Tire trouble means time loss. Any device which will minimize these deficiencies should be welcomed. The Stein Laplock Tire (T), which is made by the Stein Double-Cushion Tire Company, of Akron, Ohio, has many points of excellence, which should recommend it to the motorist. Among them are the facts that the laplock scheme does away with the use of bolts or lugs, and that the solid base precludes pinching, chafing or rotting. The gain in durability and mileage, which is one advantage of a perfectly round inner tube, is apparent, besides which this tire is so made that all the air-space is beyond the line of the rim. Besides a distributing branch at 1864 Broadway, New York City, the company is represented by agents in all the larger cities of the country.

TO permanently repair a blow-out or puncture in the tube or casing of a tire in a quarter of an hour, without heating or vulcanizing, and at the cost of but ten cents, means progress. Yet that is the claim advanced for Tire-Doh (U), which has been placed upon the market by the Atlas Auto Supply Company, 26 East Adams street, Chicago, Ill. The process is simple: Clean around the puncture with gasoline, apply some of the cement, allowing it to dry 5 to 10 minutes, then knead a little of the "doh" into the hole and around the edges. The outfit consists of a can of the "doh," one of the cement and one inside casing patch for serious blowouts.

MANY an automobilist who contemplates a different tire equipment for his car frequently abandons the idea when he finds that the tire which he prefers will not fit the rims. This difficulty seems to have been met by the Universal Rim (V), manufactured by the United Rim Company, of Akron, Ohio. This rim has been so named because it will fit all makes of tires, and carries with it the demonstrable feature in its simplest and best form. A car furnished with these rims may be shod with any of the well-known tires, without the extra expense and inconvenience of changing any part of the rim equipment.



S—The Powerful "SirenO" Auto Signal

T—Boltless and Lugless Stein Laplock Tire

U—"Tire-Doh," a Handy Quick Repair Material

V—Universal Rim, Adapted to Any Make of Tire

W—The Schafer Anti-Friction Radial Ball Bearing

X—Ball Multi-Spark Plug, Claimed to be Sootless

EASE of running is a desideratum in the make-up of a car which is not lost sight of by either maker or purchaser. Ball bearings are a means to this end, and not a few American makers, after a thorough search for the best, have adopted the Schafer Radial Bearings (W), of which Barthel, Daly & Miller, 42 Broadway, New York City, are sole importers. The friction, with the use of these bearings, has been estimated to be less than one-eighth of one per cent. of the total load carried. Unlike plain journals, the friction at starting is no higher than when running. Each bearing is handled on a complete unit that never need be taken apart and whose parts mutually retain one another.

THE spark plug problem, which is now being given an unusual amount of scrutiny, is being solved by widely varying methods, and the Multi Type (X) is one which is attracting the notice of users, due to the form of the central electrode, which terminates in a sphere, and affords a plurality of paths for the spark, so that if carbon collects at some one point the spark diverts, finding a new path between cleaner surfaces, and it is claimed for this type of plug that it will not soot up. It is made by the Ball Multi-Spark Plug Company, 917 Hennepin avenue, Minneapolis, Minn.

MANY autoists prefer to spend their vacation up in the mountains, or at some point remote from the congested centers, and one way of accomplishing all there is to be had by way of enjoyment, and the recuperation of jaded nerves, is to take the automobile along and pitch the camp in the woods. A couple of portable buildings, one to serve as the habitation and the other as a garage, renders the camp immune from the ills of a week of rainy weather, affords a wind and weatherproof house to live in, and a locked-up place for the automobile against the machinations of the occasional rover, who, like the magpie, has a penchant for everything that shines, if it is not too heavy to give him a quota of labor in the process of carrying the booty away. The Springfield Portable House Company, 412 Allen street, Springfield, Mass., offers a wide variety of portable houses from which to select the types which will accord with the requirements of the respective adventurers. The portable building idea is not a great tax upon the pocketbook of the autoist.

Capital Stock For Sale

We have a large automobile manufacturing business but need more capital to take advantage of the extraordinary opportunities offered.

Therefore, we have decided to increase our capital stock, in order to take advantage of this new business. Here is an opportunity to put some money into the fastest growing industry in America, and one that is destined to become the largest of all industries. We are offering our stock in blocks of from $500.00 to $10,000.00.

If you are interested and will write the box number given below, we will take the matter up with you in detail. This notice will appear only twice.

Address Box 5050, care The Automobile

THE BEST ADVERTISING CHASE MOTOR WAGONS

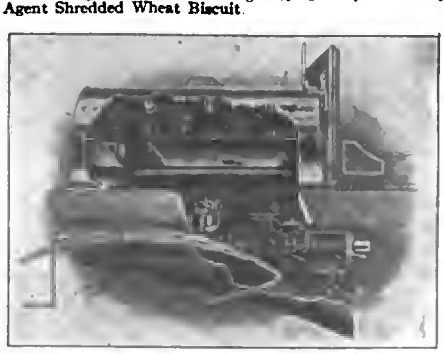
get is the word of mouth advertising of satisfied users.

Read what Mr. Turver, Western Sales Agent for Shredded Wheat Biscuit, has to say about the CHASE WAGON in use on his territory.

Minneapolis, Minn., May 26, 1910

Chase Motor Truck Co.,
Mr. George Gerem, Twin City Representative, St. Paul, Minn

Dear Sir: I am pleased to report that the Chase Motor Wagon, purchased from your Company this spring, has been in operation every day since received, and is giving excellent service. Our experience has been most satisfactory, and the expense of operation has been a revelation. We operate the car six days a week, and from ten to twelve hours per day, and our gasoline consumption per week is from 12 to 15 gallons, which compared with the boarding expense of a team of horses without considering the work done, is greatly in favor of the Chase Motor Wagon. This saving in delivery expense is one which should commend itself to every wide-awake merchant. Aside from the cost of gasoline, oil and dry cells for battery, we have had no expense whatever for repairs. In a short time I expect to send this motor wagon through western Minnesota and eastern South Dakota and shall be pleased to report to you our experience on this trip. Wishing you all success in the sale of your excellent commercial wagon, and with kind regards, I am yours truly, R. H. TURVER, Sales Agent Shredded Wheat Biscuit.



We have built Commercial wagons for every conceivable purpose. Tell us the use to which you would put a wagon and we will tell you just what success it has met in your particular line.

are built to run at all times, under all conditions. Gasoline—Electric—Open—Enclosed. Write for particulars—Some Territory still open.

VICTOR MOTOR TRUCK COMPANY
651 Main Street, Buffalo, New York

The KLAXON

"The X Ray of Sound"

Not a toy

Not meant to be "played with," but

A powerful long-range signal with a definite use and purpose.

No other automobile signal approaches the KLAXON in loudness. Both the volume and the harshness of the tone class it as a country rather than a town signal.

Yet these very qualities—unnecessary at close range—make the KLAXON absolutely ideal for distance signaling. And they are particularly valuable to warn the possible driver unseen around a blind crossing or a bush-hidden bend in the road.

Type L Klaxon, $35.00

Type S, with short projector, $30 00

It is both pleasanter and safer to give the other fellow time to make way in comfort. There are times when it is positively dangerous not to, as every motorist knows.

That harsh tone has a purpose, too. It makes people "take notice" far more promptly than a musical signal. It is in itself a warning. The hearer doesn't stop to interpret it—he acts at once and unconsciously.

Ask your dealer. And send for catalog.
